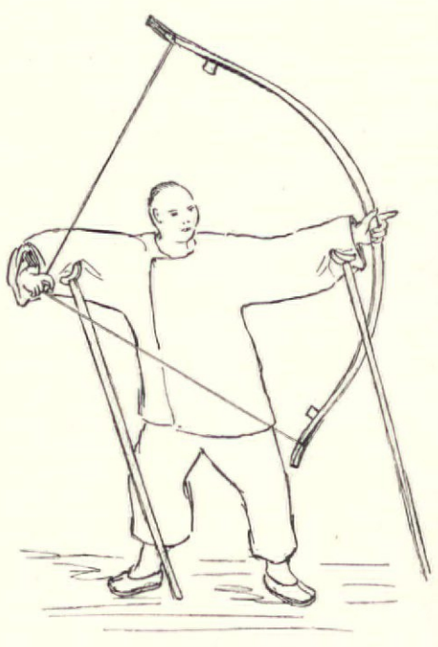
Very near my hotel was a school for archery and other military exercises. My Portuguese landlord offered to guide me to the place. There were a number of Manchu soldiers practising at the time, and they looked up frowningly as we came in. In this place were not only implements for archery practice, but evidently for bow and spear exercises on horseback, as there was a saddle mounted on a big wooden support and numerous appliances were at hand for these exercises. Heavy blocks of stone were on the floor, upon which the soldiers developed their lifting-muscles. Huge iron implements with short cutting swords at the end rested against a heavy framework of wood; these had an iron shaft 7 feet long and at least 2 inches in diameter, with the additional weight of what appeared to be a small grindstone at one end and massive ribs of iron at the other. They were so heavy that I could not lift one from the floor, yet I was told the Manchu would twirl one of these ponderous affairs over his head and thrust and parry and fence and go through a variety of evolutions with great celerity. There were bows of immense size and stiffness and I got permission to try one. In my archery days I used to shoot with what is technically known as a 48-pound bow, that is, a bow which requires a weight of 48 pounds to draw the bow down the length of a 28-inch arrow. With all my strength and hands clutched to the bow and cord I could not pull it more than an inch. It was like stringing a telegraph-pole. A Manchu then took it and not only drew it up to his ear but back of his head and held it quivering in this position for several seconds. The bow was so heavy that an assistant immediately placed props under the archer's arms to support the weight while he drew it in this way. It would almost seem that an arrow shot from such a bow by such a giant in strength would have pierced a dozen elephants in line.



Drawing Heavy Bow, Canton.

The men who were drilling were Manchu Tartars on their way to fight the French in Tonkin, and as I made rapid sketches of them they seemed ugly and suspicious. Suddenly and without a word my Portuguese guide grabbed me by the arm and hurried me out of the room in a very unceremonious fashion, nor did he explain this urgency until we had got some way from the building, when he told me that what they had said made it very dangerous to remain there. Certainly by no act had they displayed any hostile intention, though they were chattering continually and were not very gracious in their actions.

While in Japan I had been greatly interested in the potter's art and made a study of their furnaces and the various devices used in their work. I looked forward with interest to the chances of comparing Chinese methods with those of the Japanese. Shanghai did not offer the opportunity, though the jars and flower-pots seen there in such profusion must have been made in the immediate vicinity. I was told that to see the art in its fullest development one would

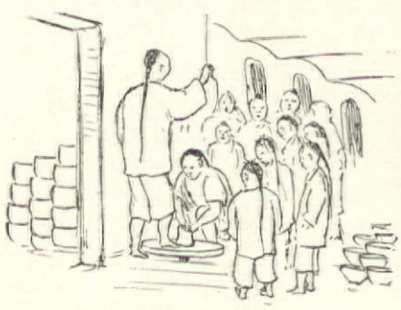
[1] Continued from No. 1380, page 78.

have to go inland 400 miles. At Canton my guide informed me that he knew of no potters' works near by, though bricks, tiles and earthen braziers were made in Canton and its neighborhood. There was a place up the river, about 30 miles, famous as a pottery-centre, but to go there safely, my landlord said, would require a passport, and this was only to be procured at Pekin. Of course there was no time to secure one, so to the American Consul I went, hoping that he might get a letter from some high official in Canton or from the Governor of the Province in which might be set forth the innocent object of my visit. But this could not be obtained; the Consul, however, informed me that only a few weeks before two Americans had gone up the river in a covered boat and on landing at the place had been mobbed, stoned, and driven to their boat, the sides of which had been smashed in, and even the Chinese magistrate who had endeavored to protect them came in for a share of the mobbing, and yet these men were not only provided with a passport from the Government, but with a letter from the American Minister. It is true these men were missionaries, and so I accounted for the rough treatment they had received. Not wishing to go alone, I tried to induce the Consul to accompany me, but official duties prevented; it was impossible to give up the trip, and with a feeling that if one behaved himself with becoming humility one might travel anywhere, I got my landlord to engage a boat with a crew of six men for the journey. A little Chinese boy who had waited upon me at the table and who knew a few words of English was allowed to go with me as guide as he said he knew all about the place. For the first and last time in the East I put a revolver in my pocket. The crew were a sturdy set of fellows, the boat was quite broad and flat-bottomed, and the men stood at their work facing the bow and pushing rather than pulling. The oars were very long and spliced, as one sees them in Japan. I sat in the bow with just room enough to avoid being struck in the face by the forward man; indeed, I had to be very careful in moving about, as the handle of the oar came within 6 inches of my head. We were five hours and a half going up the river and this against a hardly perceptible current. During the entire time of the journey the men never stopped for a single moment in their work, but kept it up with the greatest energy at the rate of thirty-two strokes a minute. It was a somewhat dubious adventure going into the country even this short distance at a time when the region was in a ferment over the French aggressions in the South.

In going up the river we passed one little settlement and then a village. The banks were low and here and there a solitary tree was seen, but the land on both sides was probably under cultivation and the people were too busy at work to saunter on the banks, and so a native was rarely seen. It was quite different on the river, for a large boat-traffic was in evidence, both in the vessels we overtook and passed and the vessels we met. Everywhere along the banks the earth seemed to be charged with old bricks, fragments of roofing-tiles, broken pottery and white porcelain, and this was certainly an indication that the river was bordered by dikes. There were no traces of river-jetties such as one so often sees in the rivers of Japan. It was curious to observe beyond the banks on either side of the river large sails slowly gliding along apparently as if the boats were sailing on the land. Our boat was so low and the dikes were so high it was impossible to see the land beyond, yet these large sails indicated, what every one is familiar with, the remarkable extent of the canal system in China. I was informed that a boat could go by canal from Canton to Pekin, a distance of 1,200 miles, with only one obstruction in the course — a mountain-chain. My experience on the river was anything but encouraging, for in every boat that passed us, and there were many, the occupants showed their hostile attitude by shouting "Fanquai" (foreign devil) and other vile epithets, and, what was more interesting, the men often making up the most hideous faces at me. To see a toothless, dirty old wrinkled Chinese stick out his tongue, contort his features and gesticulate in a threatening way was a new experience and a very unpleasant one. We finally arrived at the town at which the pottery was made. It stretched a long way on the river, and before we reached its southern border the banks were marked by huge dumps of broken pottery and porcelain, in some cases these accumulations forming conspicuous promontories jutting out from the shore. The banks also seemed filled with pottery, and here and there were tall cylindrical piles of wood, interspersed with piles of pottery such as have been already described at the city gateways in Shanghai. Here, indeed, was a pottery-town, but imagine my apprehension as to the treatment that might be accorded me after running a gauntlet of insults and hostile gestures for some 24 miles. If the boat's crew had only returned the epithets it would have been some assurance that I had at least six men as allies, but their cold and forbidding attitude showed very clearly that they endorsed the sentiments of the river population.

The place where we landed was covered with stacks of jars and pots of various kinds and I hoped that a pottery was in the immediate vicinity, but, on inquiry, my guide found that the pottery was at the upper end of the town, a place we might easily have reached in the boat. I then discovered that the guide had never been to the town and really knew nothing about it. However, there was no backing out now. The boat's crew had pulled out into the river, and the guide started ahead and I after him. I certainly did not relish going through the narrow streets with a hooting mob as an escort — a mob that had begun to collect the moment I landed. A troop of the dirtiest and raggedest hoodlums one could imagine started after us and ran ahead yelling "Fanquai" at the top of their lungs. Men joined this mob, some of them insolently thrusting their heads under the broad brim of my sun-hat and grinding their teeth at me; indeed, I believe that the looks of withering scorn and hatred can be better portrayed by a Chinese face than by that of any other race in the world. It was useless to make any friendly advances and so I did not attempt it, but looked as firm and defiant as possible under the circumstances, and kept one hand in my pocket holding on to a cocked revolver. I had already got one scare when I was so unceremoniously hustled out of a Manchu drill-room the night before, and, somewhat depressed by the treatment I had received on the river since early morning, this stern appearance I was assuming did not at all comport with my feelings. My little guide was in a complete funk, and I feared he would sneak off into the crowd and leave me alone. The boat's crew had pulled off into the middle of the river, for even they, though Chinese, came in for rough treatment, probably, for being in the employ of a foreigner. I went into a shop to buy a piece of pottery and the man looked deeply insulted by the intrusion. The extravagant sum I offered for a modelled bird, fresh from the oven, could not be resisted, and I brought back with me a single trophy of my adventures. We had gone over a mile and passed large shops of pottery, but no sign of its manufacture. The guide frequently and timidly inquired and was told to go on. Mr. Drew, at Shanghai, had informed me that the potters were a rough class compared to others, and my landlord had told me that I was to visit a region from which most of the Chinese came who landed at San Francisco and to which region they returned with stories of the heartless cruelties and indignities they had received in a Christian country, the persecutions coming from a class whose religion is most widely presented by missionaries in China, the Catholics. I could not wonder, then, at my reception. The streets were very narrow and literally stinking; the crowd increased in number and turbulence; boys ran far ahead to tell their people that a foreign devil was coming up the street. It reminded me of the way boys run ahead of a circus, and a circus it was, and I would have been gladly out of it.

Finally, and to my great relief, we turned up a narrow alley, followed by the howling mob of roughs. The alley led directly into a pottery. The potters left their work as they heard the racket, and so when I entered the place work had ceased, and a number of rough and savage-looking potters surrounded me with angry and inquiring looks. I made my way through the crowd, found a potter's wheel and made gestures to a man, evidently the boss, that I wanted to see how they turned a pot, and the sight of a fee that was probably equal to a month's wages induced him, without an expression of thanks, to shout to a fellow to go to work. I was at last to see the working of a Chinese potter's wheel. I crowded back the mob, stepped on a naked toe now and then, and fairly bluffed myself into a place where I was enabled to make a hasty sketch of a potter at work. The wheel rests on the ground and the potter squats beside the wheel. A helper stands near by steadying himself with a rope that hangs down from a frame above; holding on to this and resting on one foot he kicks the wheel around with the other foot. The potter first puts sand on the wheel, so that the clay adheres slightly. He does not separate the pot from the wheel by means of a string, as is usual with most potters the world over, but lifts it from the wheel, the separation being easy on account of the sand previously applied. The pot is somewhat deformed by this act, but is straightened afterwards with a spatula and the hand, as was the practice of a Hindoo potter whom I saw at Singapore. The ovens were like those of the Japanese; they were built in a much more substantial manner, however. The roof above them was well made and supported by brick columns. In this pottery there was not a sign of a green leaf or flower; it was as barren as a brickyard. What vivid memories came back of the Japanese potter with his charming surroundings, the offering of tea and cake, the children in the neighborhood bowing as one passed, the potter himself, a courteous soul with a love and knowledge of his craft and the work of the generations preceding him. In contrast, this Chinese pottery in a desolate yard, the ground strewn with pottery fragments, a number of workmen shouting to each other or at me, a horde of ragged men and boys howling vile names, and I thought of my long walk back through the city followed by this venomous mob of thoughtless brutes. I no longer wondered that magistrates could order these people to be beheaded by hundreds without a quiver of feeling, and, at the moment, I should have enjoyed the ordering of such a performance and might have witnessed it with equanimity. By their disputes and gestures it was evident that they could not understand the reason of my visit. That a barbarian and foreign devil should hire a boat's crew of six men and a guide and come all the way from Canton just to see a pot turned was simply preposterous and I must be a spy. A shout of contempt went up when I turned my back on the pottery and started down the narrow lane. The crowd kept up such a yelling that my approach was signalized far ahead, so that I passed through a serried array



A Potter at Work.

of frowning and angry faces. It was a relief to find that my boat's crew had not deserted me, but hearing the uproar had pulled in to the landing and was ready to row out the moment I got aboard. As we pulled into the stream a salute of contemptuous shouts and a few stones followed us. Why they had not assailed me and smashed the boat I could not understand, unless they had noticed that one hand had been in my pocket all the time, through which the outline of a rather heavy revolver might have been detected. We pulled across and down the river some distance and running the bow ashore I prepared to eat my lunch, feeling a great relief in having left the Chinese devils behind, when a number of shadows fell across me and looking up I found the high embankment fringed with a lot of peasants, men and boys, who began jeering at me. These twenty or thirty seemed so harmless compared to the hordes in the city that I felt bold, took out my sketch-book and began to set them down. This act instantly frightened most of them away, evidently disturbed by some superstition in having their pictures taken. A few men remained and defiantly made up faces at me and jerked their arms in a peculiar gesture which the guide said meant to choke me.

If one soberly considers the manner in which the Chinese have been treated by Christian nations he cannot be surprised at the attitude of the Chinese towards him. In the plainest way it may be stated that the "Foreign Devils," under the guise of a diplomatic phrase known as "spheres of influence," have stolen thousands upon thousands of square miles of territory, have robbed them of nearly every open port and have extorted untold millions in indemnities.

It was a relief to start for Canton and leave these justifiable ruffians to their filth and superstitions. On our way down the river we landed at a village which my guide said was the home of his family. He did not find a relative even, and it is probable that some ancestor

Gateway of Village.

lived there many hundreds of years ago, for such is their way of inaccurate statement that it is often impossible to find out what they do mean. (This is stated on the authority of Dr. Smith in "*Chinese Characteristics*.") We entered the village by one gate, passed through the place and out by another gate. The village being an agricultural one, the men, women and children were in the rice-fields at work, so there were few to greet me, hostile or otherwise. It was curious to see at this city-gate conveniences for burning incense to propitiate the evil spirits and bring good luck to the community.

The single trophy I brought back from the pottery-town shows fine taste and skill in modelling. In this town I discovered the origin of the common brown and green glazed pottery figures that one finds for sale in our country; figures that are more curious than beautiful and sell for a few cents. I secured one of these in Canton and have in my possession a figure which had been handed down in an old Salem family and is known to have been brought from Canton over one hundred years ago. It is made of precisely the same clay and glaze as the modern one just alluded to and must have been made in the same place. The fragments of pottery jutting out from the river-dikes were also of the same material, so that from time immemorial a succession of generations have continued making the same pottery; an illustration of the fixed and unchangeable character of these people. The interesting fact about these figures is that the modern one shows a marked deterioration in the art — a change that is seen in Japan as well as in other regions of the world.

I got back to Canton late at night wearied with the strain and anxiety of the day's adventure. In my brief experience in Canton I could not recall a single friendly or approving look, not a sympathetic return of a smile that even the lowest savage will respond to; on the contrary, a contempt and hate of me was everywhere manifest. In a Japanese town in a single day's sojourn I would establish kindly relations with a number of men and children who would come to the borders of the village to bid me good-by. At one place milk was sent to me every morning by some one who knew that the foreigner drank milk; at another place some little souvenir was given me by the servant of some one just as I was about riding away. I wanted to see the good points of the Chinese, but utterly failed to get in touch with any one save my companions at Shanghai, who had lived in Hartford for a few years and had, doubtless, been slightly affected by this foreign contact. Artificial as the politeness of the Japanese is said to be by some English writers, I recall the expression of one who said that politeness was like an air-cushion; there was nothing in it, but it eased the jolts wonderfully. In my short experience with the Chinese I do not recall the faintest indications of kindliness, politeness or urbanity; whether high or low in station, their attitude was always the same. Now, I know there must be kindness, gentleness and politeness among them. In the higher classes etiquette is developed to a degree unknown with us.

The reception a foreigner encounters in China is due to an intense dislike of us, coupled with an absolute contempt for all we do and for all we have accomplished. It seems strange that the cheap crowd of Chinese who come from the poorest regions around Canton and follow the menial occupation of washing clothes despise us and all that our civilization has acquired. They burn our gas and kerosene, ride in our cars, profit by our medical practice, appear in our public courts for justice, follow time with a Connecticut clock, use our mails, yet look on their own ways as infinitely superior to ours in every respect. They are, undoubtedly, deeply impressed and flattered by the fact that in some matters we imitate them. If they are taught history in our mission-schools they know that many of our arts originated in their own country. The art of making paper, printing, the mariner's compass, the manufacture of gunpowder, white porcelain and silk are all due to the Chinese. They further note the use of raised beds, tables and chairs, and probably laugh at our limited use of the wheelbarrow, which, with them, conveys passengers as well as merchandise. They notice the same activity and bustle on the streets, our food is in many respects not unlike theirs, and they go to our markets and without trouble find articles of food to their means and taste, and they observe their national drink dividing the honors with coffee. They further notice that, like their own people, we love noise, and in this matter they probably regard us as superior in that our barbarous factory-whistles wake up invalids in the next county while their racket may reach only a few squares. The factory-whistle and the grinding trolley-car with its clanging bell they delight in and we make no effort to suppress. Their pride must be flattered, too, when they discover that we celebrate our great national birthday precisely as they celebrate their great days and, what is more, we send to their country for the fire-crackers with which to do it. If our people die in any part of the world the body is transported across continents and oceans to be interred in home burial-places. The Chinese transport their remains in the same way to their native country.

In recognizing these similarities they see an approach to their own people, but beyond these matters they are totally blind. Cleanliness, sanitation, good roads and schools, coinage, postal-system, fire-apparatus and all the wonderful development of steam and electricity and the thousand instrumentalities of life that we have acquired through the persistent study of the behavior of nature's laws make no more impression on their brains than it would on the brain of an ox. In that respect they represent a savage race.

EDWARD S. MORSE.

A CRITICISM OF THE SHAW MONUMENT, BOSTON.

IN his book entitled "*The Field of Ethics*," George Herbert Palmer, Alford Professor of Philosophy in Harvard University, treats of the relations between ethics and æsthetics, and in illustration of the kinship between certain traits of beauty and goodness, he gives the subjoined description and estimate of St. Gaudens's Shaw Monument:

"In seeking for a beautiful object which I may fairly assume to be widely known, what can I select better than the wonderful bronze memorial which stands on Boston Common, opposite the State House? All of us are familiar with it, — the Shaw Monument, — and we all feel the sublimity of its motive. It represents a subject race moving towards freedom, seeking that freedom by its own exertions, yet under the guidance of a people more developed than itself. This complicated and exalted motive is made by the artist to address the eye. As a work of art his picture appeals to us not merely through its sentiment, but by the entanglement of this with certain experiences of vision. Visual pleasures of a peculiar sort are made to fortify patriotic emotion. What, then, are these visual pleasures and how are they adjusted to stir our sense of sublimity?

"First, there is rhythm. This multitude — a dozen or more in the foreground, suggestions of an indefinite troop behind — is no mere multitude. It is bound together by harmony of answering lines, and gives to the eye such concord as measured verses give the ear. Then there is its typical character. These men are negroes. The strange and half-formed faces, the large and awkward feet belong only to one race. There is no feature which is not distinctive of a specific people, and all the kinds of man which could enter into a racial army are here represented. Here is the drummer-boy, young, eager for

the fray, delighting in adventure. Here the man of vigorous years, performing his duty with cheerful stoutness, not thinking too much about it or himself. And here the aged man, whose great opportunity has come after a life of waiting.

"Inclusive, therefore, as the piece is, we feel it to be one, however minutely its details are inspected. How united, for example, are its lines of motion. The end which this race seeks is not yet attained. But half-men yet, their goal is ampler manhood. It lies ahead, and towards it every line converges. To these resistless marchers those words of Shakespeare apply, by which he described the minutes of our life: 'In ceaseless toil all forward do contend.' Everything here contends forward. The very slope of the muskets, though never allowed to become mechanical through parallelism, beats out the same reiterated impression — the impression of onward movement. There is no portion of the figures too unimportant for the artist to have studied with this in view. He has related his soldiers' legs, has harmonized their feet; and as these rise on the toes, all their ungainly curves combine to emphasize the forward swing. Spontaneous as all appears, not an ill-adjusted heel can be discovered, no part which is not in some way called to make concord with its fellow-part.

"And if there are features of the composition which might at a first glance seem to jar its chief lines, these will be found on closer study to confirm the ocular argument. Thrown out a little from the rest — they a troop of trudging negroes, he the most refined of white men — sits an officer on his horse. The horse is lightly reined, and the harsh curve of his neck and body breaks the lines of the piece and throws this part of the composition out of full concord with the surroundings. But is not the detachment needed? Does it not reënforce both thought and visual pleasure? Contrast is involved in the subject, and perhaps this jarring of the dominant lines heightens their effectiveness. And then how beautifully the multitude is once more united and its community of aim displayed in the floating Victory above! Hardly noticed by the moving figures, she sweeps over them in her trailing robe, welding all together and assuring their common end.

"When we try to sum up our general impression of the beauty of this monument, I think it will be found in its exceeding harmony. In it there is nothing superfluous and nothing lacking. That is its striking characteristic. If any doubts visit our minds about its perfect beauty, they take the form of pointing to something in it which does not quite go with the rest. Is the figure of Victory rather long? That is to ask whether it is truly proportioned to its surroundings. Does it attract attention to itself, or fix attention on the whole composition? We may think the horse of Colonel Shaw a little too natural, and condemn him for backing too much as a real horse would. If so, we judge that the lines of the creature detach themselves too palpably from the rest of the composition and do not assist, as they should, to confirm human action. That is, in criticising the piece and deciding whether it is singularly beautiful or a worthy work with blemishes, we scrutinize its concord and ask how fully it is organic, whether each part in it is demanded by every other part. If nothing capricious appears, if the single portions, however minute, have been dictated by the law of the whole, then of course we count it beautiful. If we think we can detect any portion which sticks out, hangs off from the rest, and claims attention for itself, then we say that in this respect it fails.

"But is it true that no one can enjoy the Shaw Monument without going through some such analysis of its beauty as I have given here? Far from it; such analysis is quite as likely to hinder the enjoyment as to help. We have approached the matter as students of beauty, trying to bring its elements distinctly into consciousness. But that which makes a beautiful work of art most beautiful is that it calls for no distinguishing consciousness. The separate parts are not specifically observed. The total makes a single impression. The work of art appeals not to intellectual verification. It reaches the unity which should characterize it only when it can be grasped at once by momentary feeling. So long as it is necessary to go over it piecemeal and say, 'This single part accords with that single part and with the other single part,' we may be sure the result is flabby. If the work were really coherent, it would say so at a glance. The crowds who pass before that august bronze and feel the sting of its beauty do not know that they are impressed by congruent features, rhythmic figures, almost parallel muskets, lines of uplifted heels, and converging curves. With no such things are they concerned. To notice these is to disparage the total beauty. By the artist these things are studied before the beauty is born; by the spectator, when the thrill of it is a little passed by.

"We may probably conclude, then, without search for supplemental elements, that this principle of organic wholeness is a central characteristic of the beautiful object we have been examining. And is it not also a beauty everywhere? In a beautiful piece of music there are no accidents. Everything falls there by appointment, nothing by mere happening. The whole demands every note that sounds, and no phrase could have differed from what it is. The case is the same with beautiful writing. When our essay or story turns out badly, it is because we have put in matters which were unnecessary or have omitted what the reader would really need to know. The parts straggle or do not go entirely well together, and in consequence the piece is not integral, solid, firm in texture. It is true my examples have thus far been drawn from the field of the fine-arts — that is, from beauty humanly constructed. But where beauty is an affair of nature and not of conscious construction, its principle is the same. In a beautiful human body 'head with foot hath private amity.' In calling a landscape beautiful, I mean that it possesses such harmony of lines and colors as would have been placed there by a conscious artist. Its easy wholeness is just what an artist labors to produce."

ON COLORED WAX STOPPINGS.[1]

MOST papers begin with an apologia — a disclaimer of authority on the part of the author — an appeal for indulgence because of the writer's youth, or age, or lack of time, or literary inability, or what not; and I have no wish to depart from a form which at least is founded upon experience and the survival of apologetic paper-readers. We all hope that modesty may mollify our audience and that we may have the good fortune to really meet and talk to the "gentle reader" whom our forefathers used to woo in their urbane prefaces. Accordingly I apologize for this paper — a paper which really is better described as a practical note, and a practical note, moreover, on the simplest form of inlay in wood — namely, colored wax stoppings.

The dictionary tells me that "inlay" consists of "pearl, ivory, choice woods, or the like, inserted in wood." Well, you cannot compare colored wax stoppings with such inherently beautiful materials as "pearl, ivory, or choice woods," therefore you must accept simplicity of material in the means at your disposal; at the same time, you may be reminded that fine results have been achieved in the past by these simple means, and so it may be worth while to recall attention to a form of inlay which has fallen into neglect.

If any one will go to the Victoria and Albert Museum, in one of its darkest corners he will see a number of *cassones*, old chests, covered with incisions and carvings. These chests have been filled-in with colored wax. On the oldest, which dates back to 1530, a certain amount of color still remains in the incisions, and where the color has come out, from its being incised, it still tells quite firmly, as designed. What were these *cassones*, and how were they done? So far as I know, they were the wedding-gifts of fairly well-to-do people to the bride — at least from the parents to the bride. They held her costumes — her trousseau. On the outside of them were carved romantic allegories, as was quite fitting in a piece of furniture that had so romantic an origin. You wonder how this was done. When you look a little closer you find that the work is incised, and that the incisions have been filled-in with colored wax — green and red wax as a rule. They had three ways of expressing their design in this method; it is either done by spaces of color silhouetting the figures, or else it is done by lines, or it is done by spots — and in the lines and in the spots you will find nearly all the stopping has vanished; but in the larger spaces you will see that the stopping has remained fairly firm — for 500 years. I attribute that to the fact that the larger spaces would be got out with small gouges and chisels, and that therefore there was a key at the bottoms; and that where the lines and spots came it was with the blade, just cut down like engraving, and that there was no key in the bottoms in those lines, so that in time the stopping came out. That has been the case. But I think that you will be surprised to see how beautiful the thing still is; it has faded, yet it still possesses the bloom of its early beauty. You feel what a beautiful thing it is. It is not the least like a painting, part of which has been effaced, and which always has a look of disease — an appearance of something or other gone wrong; but this merely looks a little faded. Just as in another art altogether — the *carillons* of Bruges — although some of the bells are wanting, they still sound extraordinarily beautiful, with that dim misty sound of broken air. So in these old *cassones* there is a broken air of melody in the design that still remains a thing of beauty, although the wax colored inlay has gone.

These old examples show what fine things can be done in this method by artists who understand the graphic possibilities and the limitations of flat surface-decoration.

About fifteen years ago, urged on by admiration of these old examples, I made several small experiments in this method, and as I have been asked by the Council of the Royal Institute of British Architects to give the results of my experience — which has now stood the test of some time — I am glad to repeat the methodical notes which I contributed on this subject to the July number of the *Art Journal* last year. First trace your design on the panel of wood to be incised; cut it, either with a V-tool or knife-blade fixed in a tool-handle; clear out the larger spaces with a small gouge, leaving tool-mark roughness in the bottoms for key; when cut, stop the suction of the wood by several coats of white hard polish. Your colored stoppings you must make. Resin (as white as you can get it), beeswax, and powder distemper color are the three things needful, and "*Spon's Workshop Receipts*" will put you into the right way of making your stoppings — with this reservation, reduce the proportion of resin, as this tends to make the wax over-brittle. For running the melted wax into the incisions — that is, for the inlay — I have made use of the small funnel with handle and gas-jet affixed which I have here: by means of india-rubber tubing it is attachable to the nearest gas-burner, and thus a regulated heat can be applied to the funnel. When thus attached and heated drop pieces of wax of the intended inlay color into the funnel, and soon there will be a run of melted wax dropping from the end of the funnel-spout, which is easily guided by means of the wooden handle, and thus the entire panel may be inlaid with the melted wax. When this is all done

[1] A paper by Heywood Sumner, read before the Royal Institute of British Architects, and published in the *Journal* of that Society.

clear off the superfluous surface wax with a broad chisel so as to make the whole surface flush, and then, if you have rightly stopped the suction of the wood by the white hard polish, your panel should all tell with clean sharp contrast of flush wood-lines against colored stopping surface, color stopping lines against wood surface: if the suction is not stopped the hot wax will enter the grain of the wood and stain it.

I have also filled-in incised panels successfully with japanner's gold-size and powdered distemper color, using a palette-knife to distribute the slab mixture. This sinks as it hardens, and will probably need a second filling-in to make it a flush job.

In both cases, I should add, the stopping has proved durable and tenacious, but the melted wax gives a more interesting and accidental result, and is better suited for designs that depend on spaces of color-stopping for their effect.

Individual preference will suggest the wood to be used for this work, a close grain being the one thing needful. The specimens I have brought here are lime, birch, and a box of *kauri* pine. The last you will see is not sufficiently close-grained and is slightly wax-stained in the inlay, but it was made where choice of woods was limited. As to design, that which is suited to this sort of inlay may be compared to a broad sort of engraving. The lines must be wide enough to hold the wax and the spaces of color must have occasional ridges — like cloissons — in order to hold the wax and to keep the flush surface of the panel when the chisel shaves it down; but within certain limits, which must be felt, the manner of design is more free than is the case with inlay composed of veneers of hard material; and the absence of beauty of material — *e. g.*, pearl, ivory, or choice woods — must be forgotten in the beauty, fancy, and austere freedom with which the incised decoration is expressed. Certainly, I think that the specimens which I have spoken of in our Museum show all these qualities of design — beauty, fancy, and austere freedom of handling — and accordingly I cannot do better than to urge the claim of these old relics to be studied both for method, application, and romantic design of colored-wax inlay in wood, and to hope that others may be fired with the desire to further experiment in this simple method.

As to its application, I will not suggest beginning with results — with such fine results as the old examples to which I have called attention, but will turn to real homely requirement, from which a more stately application might arise. I think that we have in our time lost a number of nice little simple household things that our forefathers used to enjoy. Our grandmothers, when they made tea, used to have a tea-caddy. They had a nice tea-caddy with delightful inlay. Where is that tea-caddy gone? We drink more tea than ever, but the tea-caddy has departed. Then some of us smoke cigarettes, but the cigarette-box makers do not seem to care to use this process of inlay. Again, when I was at school I had a nice brass-bound desk with a secret drawer in which I was always hoping to find money. Those are quite things of the past. When I send my boy to school, and ask for a desk, I get a deadly dull thing with a lump of brass in the middle, that a boy, if he tried with both hands, could not get fond of. Then, again, clocks. Just think of the beauty of a clock-case. We all want to know the time nowadays, and we bustle more than ever; but for modern artistic clock-cases there seems very little demand. There is a demand for chiming clocks — why I do not quite know, since they are maddening things. But no one seems to crave a stately clock that will make him feel a better sort of man! This qualification is very true, for if you have a fine thing in your house you try to live up to it. There is another neglected thing, the barometer. It seems odd to me that so admirable an instrument has never suggested fine craftsmanship to the imagination. Why should not craftsmen in inlay give us these quiet, homely things that we are always needing and using? If anything I have said to-night were to turn our really skilful cabinet-makers — the men who understand the whole mystery — to this simple side of the craft, I should feel that I had done a very good evening's work.

THE UNDERGROUND PASSAGEWAYS OF ENGLAND.

THERE are, however, numerous traditions of other achievements of underground architecture which are not altogether, or at all, unauthentic. There is the often-talked-of passage from Highgate or Hampstead to St. Albans, invariably associated with the redoubtable Dick Turpin. Certain traces are said to have been found, and of the many hazarded explanations perhaps the most plausible is that which suggests that it was the commencement, in Roman times, of an enormous military work between London and Verulamium. There was said to be an underground passage in connection with Sir Thomas More's house at Chelsea, though neither its destination nor dimension seems to be known. Tradition asserts, too, that there was a similar way from the Tower of London to the Old Palace at Eltham; and a less shadowy authority declares that it was from a subterranean passage at Hampton Court that Charles I effected his escape from the jailership of Colonel Whalley. Relating to the other principal actor in the grim drama of rebellion and regicide is the tradition of an underground passage from Cromwell's house at Westminster, and readers of Dumas will not forget the effective use he makes of this belief in "*Twenty Years After*."

It is only natural that many of these traditions of underground passages and dwellings should associate them with religious houses or churches, the obligations of sanctuary, the political importance of ecclesiastics, and the fluctuating relations between Church and State, making secrecy of transit and abode often absolutely essential. There was the alleged subterranean communication between Southampton and Netley Abbey; another between Warwick Castle and St. John's Priory; another between the Castle and Priory at Lewes. From the famous Abbey of historic Tewkesbury there ran, it was said, a passage underground to Malvern — possibly to the monastery founded there by the Confessor.

From Durham Cathedral, "half Church of God, half tower against the Scots," the monks could pass to the beautiful Abbey of Kirkstall; from the stately Benedictine Church at Reading, whose massive walls, 8 feet thick, had a circumference of half a mile, a similar passage ran, so the story goes, to Caversham.

When any of the mighty Nevills, Lords of Middlesham, needed ghostly counsel, it was said that a confessor could come, all the way underground, from the distant Abbey of Gervaux; and the Percys or Seymours of Wressil could in like unseen manner attend mass or evensong at Howden Church, 4 miles or more away. The pious nuns of Watton, concerning whose rigorous discipline Fosbroke relates so many quaint particulars, were wont, tradition said, to attend at the Holywell at Kilnwick, and there perform miracles of healing.

But what doubtless seemed the greatest miracle of all was, how they got there, till the mystery was put an end to by the discovery of a subterranean passage to the nunnery. From Guisborough Priory a tunnel ran for a mile and a half to a place called Toccotes, and in the midst of this, so we learn from Ord, was a mighty chest of gold. Easy enough to be plundered, it would seem, since its only guardian was a raven — but this raven, like Poe's,

> Had all the seeming
> Of a demon that is dreaming,

and when any venturesome wight approached with felonious intent, the seeming came true and the dreaming ended, and the Foul Fiend himself stood revealed. There was a passage, the old books tell us, between Someries Church and St. Mary's, Luton, and another from Newnham Abbey to the priory at Bedford, some 2 miles distant. This appears to be fairly well authenticated, and perhaps the same may be said of the tunnel between Larkbeare House, in Exeter, to the castle and cathedral, and of that between Sawley and Whalley Abbeys in Yorkshire, stated to have been 7 miles long, and of which traces are said to be found. Intervening water was as little of an obstacle in those days as now, always assuming the existence of these reputed passages.

From Pontefract, for instance, a tunnel was said to run under the moat, and have its exit at a mound a mile distant; and from Richmond Castle a similar passage led to St. Martin's Priory, on the other bank of the river Swale. Still more staggering are the legends which affirm a submarine communication between the Giant's Causeway and Rathlin, a distance of 8 miles, and between the coast of Wigtonshire and the Isle of Man, about 30 miles. These find their parallels in the legendary passage from Naples to the Castle d'Elmo, and that convenient tunnel, 4 miles long, which led from the mainland to the delightful island of Capri. But there is nothing new, more especially in the way of underground architecture, and we need not, accordingly, be astonished at reading that ancient Egypt boasted its subaqueous passage between Assuan and the island of Elephantine. — *London Times.*

ILLUSTRATIONS

[*Contributors of drawings are requested to send also plans and a full and adequate description of the buildings, including a statement of cost.*]

CORRECTION. — Owing to an unfortunate mixing-up of proofs, there was published last week under this heading the title of the Birmingham University, an illustration which was not actually contained in the issue. The plate which ought to have been entered as among the illustrations was the Prince Regent's Theatre at Munich.

THE UNITED STATES COURT-HOUSE AND POST-OFFICE, SALT LAKE CITY, UTAH. MR. JAMES KNOX TAYLOR, SUPERVISING ARCHITECT, WASHINGTON, D. C.

EXTERIOR DETAILS OF THE SAME.

NOTES AND CLIPPINGS

BLASTING-RIGHTS ON MANHATTAN ISLAND. — Justice Giegerich of the Supreme Court has refused to continue an injunction granted to Maria del Carmen Santos de Carvajal, the owner of the premises at 214 West Twenty-fourth Street, restraining the Young Men's Christian Association, and Canavan Brothers, the contractors, from blasting in an excavation adjoining the plaintiff's premises. The latter claimed that the blasting was seriously endangering the safety of her building. The contractors answered that the work was being done with the utmost care, and pointed to the fact that no damage had been done by them to other buildings similarly situated, where the work has been completed. The plaintiff based her case on a decision of the late Justice McAdam that the owner of a house erected upon a stratum of rock extending through adjoining premises may enjoin the owner of the adjoining premises from blasting the rock, where the blasting, even if conducted with the greatest care, would cause serious injury to the house. (Brennan *vs.* Schreiner, 28 Abb. N. C., 481.) Justice Giegerich holds that this case has been overruled by the Court of Appeals in Booth *vs.* Rome, Watertown and Ogdensburg Terminal Railroad (140 N. Y., 267), where it was said: "The rocky surface of the upper part of Manhattan Island makes blasting necessary in the work of excavation, and unless permitted the value of lots, especially for business uses, would be seriously affected. May the man who has first built a store or warehouse or dwellings on his lot, and has blasted the rock for a basement or cellar, prevent his neighbor from doing the same thing when he comes to build on his lot adjoining, on the ground that by so doing his own structure will be injured? Such a rule would enable the first occupant to control the uses of the adjoining property to the serious injury of the owner and prevent or tend to prevent the improvement of property. The fact of proximity imposes an obligation of care, so that one engaged in improving his own lot shall do no unnecessary damage to his neighbor's dwelling, but it cannot, we think, exclude the former from employing the necessary and usual means to adapt his lot to any lawful use, although the means used may endanger the house of his neighbor. It (the blasting) was not an act which, under all circumstances, would produce injury to his neighbor, as is shown by the fact that other buildings near by were not injured. To exclude the defendant from blasting to adapt its lot to the contemplated uses, at the instance of the plaintiff, would not be a compromise between conflicting rights, but an extinguishment of the right of the one for the benefit of the other. This sacrifice, we think, the law does not exact. Public policy is promoted by the building up of towns and cities and the improvement of property." — *N. Y. Times.*

THE "RIGHT OF WAY" AT STONEHENGE. — There are few privileges of which the rural population of England are more tenacious than those of right of way. Any attempt to close an old footpath, even if unused and almost forgotten, at once precipitates a fight. A question of this sort has now arisen in connection with the venerable ruins of Stonehenge. A year ago Sir Edmund Antrobus enclosed Stonehenge with a barbed-wire fence, and imposed a charge of one shilling for admission to see the monument. The immediate object was to protect the stones and raise funds for certain works of restoration and exploration. But the effect was to deprive the nation of free access to a national monument. Not unnaturally, therefore, the question at once arose whether the enclosure was lawful. There seems to be no doubt that Sir Edmund has become the possessor of the land on which the stones stand, but it is equally certain that the public have always enjoyed the right of free access to them. One fact alone is sufficient to prove the antiquity of the footpaths. The outermost circle of Stonehenge consists of an earth vallum worn down by time and weather, but still rising some feet above the natural surface of the ground. The paths in question cut through this vallum, which rises abruptly some three feet or so on either side of them. In other words, so persistent has been the use of the roads that it has gradually worn away the earth where the circle is crossed until it has brought the surface to the natural level of the ground. The whole matter is under investigation by the local County Council. One fact of singular interest has been elicited. There seems to have been a special gathering every year, numbering thousands of persons, at Stonehenge to witness the rising of the sun on the 21st of June. As Stonehenge, according to the best opinions, was originally constructed with reference to rites performed at this very moment, it is supposed that there has been a public assembly on Salisbury Plain at midsummer ever since the circles of Stonehenge were first completed. — *N. Y. Evening Post.*

A FEAT OF BRIDGE-BUILDING. — The double tracks of the Pennsylvania Railroad cross the Schuylkill River at Girard Avenue, Philadelphia, on a stone-arch bridge with a single steel-truss span over the middle channel. This was recently replaced in 15 minutes, without the least delay or interruption to the almost continuous traffic of long, heavy freight-trains and high-speed expresses which cross the bridge every hour in the twenty-four, without obstructing the river. A temporary steel span was built alongside the old one and at a lower level, so that its top was a little below the bottom of the old structure. On this was erected, in the usual way, the complete new span with the tracks laid on it. Powerful hoisting-engines were set on platforms at the ends of the old span on the opposite sides of the bridge, and operated four sets of tackle, by which, after the tracks had been cut, both spans, weighing together nearly 2,000,000 pounds, were pulled sidewise on double tiers of long horizontal rails with over 300 solid steel rollers between them. In this way the old span was displaced by the new one, which followed it like a very substantial shadow, until permanently seated in exactly the same position. Two and a half minutes after the last train crossed the old span, the connections were broken, the engines were started, and in 2½ minutes more had pulled both spans simultaneously the full distance of about 37 feet. In 8 minutes more the first train had passed over the new span, and it was in regular service. The engines and tackles were shifted, and a set of greased rails was arranged at a low level, on which the temporary span was pulled to a position directly below the old span, and served as a support while the latter was taken to pieces. The great weight of the spans, the difficulties from incessant traffic, and the speed and accuracy with which the spans were moved, make this one of the most remarkable of feats. — *Frank W. Skinner in the June Century.*

CONCHOLOGY AND SPIRAL STAIRS. — One of the most remarkable architectural structures in existence is the left-handed spiral staircase in the Château de Blois, Touraine, built during the sixteenth century from designs by Leonardo da Vinci. In the May number of the *Monthly Review*, Mr. Theodore Cook shows that the design of this staircase corresponds so exactly with the spirals on the common Mediterranean shell known as *Voluta vespertilio* as to leave little doubt that the artist had that shell before him as his model. The spiral on the central column of the core of the staircase corresponds exactly, for instance, with the spiral ridges on the *columella* of the volute, as seen in section. This of itself would be strong, although perhaps not absolutely convincing, evidence as to the origin of the design. But the staircase has also an exquisite outer balustrade, which shows a correspondence to the coils on the external spire of the shell as close as that which obtains between the interior of the staircase and the *columella* of the volute. Such a dual resemblance could scarcely be the result of coincidence, and the author seems justified in the view he has taken. It is remarkable, however, that the spirals in the staircase run in the reverse direction to those in normal examples of the shell, that of the central shaft being left-handed instead of right-handed. The spirals are, in fact, those of a "reversed," or dextral, example of the shell, of which, perhaps, one in a million occurs in nature. That Leonardo da Vinci had such a reversed shell from which to copy is unlikely; but it is known that he was left-handed, and a left-handed man would naturally draw a reversed spiral. The author has in hand a work on natural spirals in general. — *Building News.*

WHITE ONYX DEPOSITED IN ARIZONA. — A very large deposit of white onyx has been found in the Baca land-grant in Yavapai County, recently purchased by an English syndicate. One of the specimens, weighing 50 pounds, is of solid creamy white. The deposit is said to be the only bed of white onyx known. It is without a flaw or crack. The vein is 5 feet thick, extending 800 feet in one direction and 1,000 in another. It is covered by 250 feet of limestone, which probably accounts for its freedom from cracks, flaws and discolorations. Slabs of almost any marketable length can be taken out. — *Exchange.*

CHARACTER OF THE DEPOSIT UPON ST. PAUL'S. — Under the coping of the balustrade surrounding the Stone Gallery at the base of the dome of St. Paul's, in London, is a black deposit about three-fourths of an inch in thickness. This deposit resembles boiler-scale, and it has lately been subjected to chemical analysis to determine its nature. The analysis reveals the curious fact that it is a sulphate-of-lime, or gypsum, and it is assumed by the chemists that it was deposited by the air. Their argument is that in two hundred years the smoke and gases from London chimneys have charged the rains with sufficient sulphurous and sulphuric acids to make this deposit. — *Boston Transcript.*

THE FORESTS OF RUSSIA. — The gradual deforestation of Russia is attracting increased attention throughout the Empire, and the Forestry Society as well as the Forestry Department of the Ministry of Agriculture and Domains are discussing means for regulating the consumption of timber and for propagation. There does not seem to be any great cause, however, for apprehension, as a recent official report states that forests in Russia now cover an area of 188,000,000 hectares (464,000,000 acres). Among European countries, Sweden comes next with 44,000,000 acres of forests. In Russia the forests cover 36 per cent of the whole area of the country. The Swedish forests occupy 44 per cent of the total area, and the Austro-Hungarian 32 per cent of the territory of the dual monarchy. Reckoned by the population there are 4.9 acres of forest to each inhabitant of Russia, 9.5 acres in Sweden, 10.4 acres in Norway, and .69 acre per head in Germany. The forests have a greater importance for Russians than for people of Western European countries, as villages and country-houses are largely built of wood, stone and brick houses being almost unknown, and the forests furnish the main sources of fuel supply. — *Journal of the Society of Arts.*

A LARGE CRANE. — German papers claim that "the largest crane in the world" is to be seen in use at Kiel. Its own weight is 450 tons, and it is capable of lifting as much as 150 tons. Its arm stretches 50 yards from point to point, and is 50 yards and more high above the foundation. It is worked by electricity. — *Exchange.*

THE RESTORATION OF THE ERECHTHEUM. — The Greek Archæological Committee has decided to restore the Erechtheum. The greater part of the famous ruin on the Acropolis is still standing, and the fragments necessary for its complete reconstruction are all lying around. — *N. Y. Evening Post.*

A JAPANESE SLEEPING-CUSTOM. — The Japanese never sleep with the head to the north. This is because the dead in Japan are always buried with the head in that position. In the sleeping-rooms of many of the private houses and of hotels a diagram of the points of the compass is posted upon the ceiling for the convenience of guests. — *Exchange.*

NOTES AND CLIPPINGS. 96

IT would take a very strong and nearly unanimous appeal from our subscribers to induce us to continue the form of publication which, during the current quarter, has been given experimentally to our International Edition. We are not satisfied with the practical working of the new method, which seemed to have the promise of many desirable possibilities in its favor, and believe that no mistake will be made in returning at the earliest practicable moment to the original form of publication. From the first issue for July, therefore, subscribers to the International Edition will again receive their copy in its familiar blue-covered weekly form.

MR. A. J. OVERMIRE, a Minneapolis architect, makes some comments on the great and increasing fire-tax in this country which are favorably mentioned by the New York *Evening Post*. Mr. Overmire's most novel suggestion, that municipalities "should take action against owners who disregard common-sense principles of fire-protection" is not, unfortunately, a very practical one, for the reason that "the common-sense principles of fire-protection" are very ill-defined, and are constantly changing, as new materials and methods of construction come into use; and to authorize municipal officials to prosecute owners of real-estate on such uncertain and arbitrary grounds would be to put in the hands of political heelers a weapon which would be used for blackmailing on a gigantic scale. If the principle of neighborhood responsibility, which is applied nearly everywhere in Europe, outside of Great Britain, were accepted here, as some of the most thoughtful insurance men now urge, careless and selfish owners of buildings would be sufficiently held in check by the fear of civil suits for damages, without needing the application of the criminal law. Mr. Overmire, however, indicates, unconsciously, a less radical method by which, pending a change in the laws, the situation might, so far as underwriters and the public are concerned, be immediately and greatly improved. Speaking of the fact that the insurance-companies, during the last year, carried on their business at a net loss of about nine million dollars, he says that in Philadelphia, for the last seven years, the net losses in the congested district have been five times as large as the total net loss, "because the premiums, as a whole, reduced the loss in that city, taken as a whole." This means, apparently, that the profit on the premiums on insurance outside the congested district made up the losses in the latter territory. Supposing, then, for the sake of making the matter clearer, that the amount of insurance carried in the congested district was the same as that carried outside, the obvious inference from the statement that the loss in the congested district was five times as great as the total loss is that the policy-holders outside the congested district paid premiums five times as great as they should have been, in order to make up the losses which the underwriters suffered from charging their customers in the congested district only one-fifth as much as they should have paid. This is not the first time that we have called attention to the fact that insurance-companies in this country, notwithstanding their professions of adapting the premium rate to the hazard, still grossly overtax the owners of dwelling-houses and other good risks, to make up the losses which they suffer from underbidding each other to secure large contracts on department-stores and warehouses, the premiums on which, by their own confession, are totally inadequate to the probability of loss; and the Philadelphia figures, which Mr. Overmire seems to take from official sources, show that we have not overstated the matter. Under these circumstances, we may, as representatives of a profession interested solely in the art of building, be permitted to say that if the insurance-companies in Philadelphia, instead of groaning and lamenting, would forthwith add four hundred per cent to their premium rates in the congested district, reducing them from that standard only in consideration of the adoption of safeguards which every architect understands, and would deduct four-fifths from the premiums paid by the owners of dwelling-houses outside the congested district, they would do more to call public attention to the conditions which increase or diminish the fire-hazard, and to promote the adoption of improved methods of construction and maintenance of city warehouses, than could be accomplished by criminal prosecutions in every State in the Union.

IT is rather amusing, in view of the lectures which American architects continually receive from insurance officials in regard to the superiority of foreign methods of building over our own in regard to resistance to fire, to read the account of a real fire in London or elsewhere, with the comments made upon it by the newspapers. A few weeks ago a fire broke out in a warehouse in London, in the quarter of the Barbican, where a large number of such warehouses are clustered together, with narrow streets between. How the fire originated is not stated, but it spread very rapidly, until nearly forty buildings were destroyed, with property to the value of more than five million dollars. In its remarks on this fire, the *British Architect* says, not without reason, as even the profession in America will acknowledge, that "internal partitions need no longer be made of match-boarding," while even "automatic sprinkling arrangements have got beyond the experimental stage, and ought to prove of real utility in coping with the incipient stages of a fire outbreak." The idea of fitting a storage warehouse with partitions of matched boards would seem preposterous to any American architect, and, in this country, at least, automatic sprinklers are so far beyond the experimental stage that their utility in putting out incipient fires is no longer a matter of speculation. The *British Architect* observes, further, that "the insurance-companies seem also to be disposed to quote reduced rates for buildings constructed on fire-resisting methods." It is indeed gratifying to learn that English insurance-companies are "disposed" to find the fire-risk greater in warehouses divided by matched-board partitions, with sheet-glass windows, opening on narrow streets, than in those glazed with wire-glass, and subdivided by partitions of masonry, but we can hardly infer from this circumstance that knowledge of such matters in England is enormously superior to that attained in this country, where insurance schedules have for many years taken account, in rates, of nearly every detail of construction affecting the fire-hazard.

THE fact seems to be that English methods of building are, at present, inferior to ours, and the comparative immunity of English towns from fires is due less to the solidity of their houses than to the methods of heating them. Open fireplaces, although they offer a certain danger, are, at least, easily watched, and, when there is no fire in them, which is the case with most English fireplaces all the year round, they present no hazard at all. If the same buildings were heated by steam or furnaces for six months in the year, as would be necessary here, and were provided with elevators in the American proportion, it is doubtful whether they would resist fire any better than our buildings. In another case in London, a man was working at night in a shop on the ground-floor of a house. In moving a lamp, he dropped it, and the oil, running over the floor, took fire. The fire spread so rapidly over the house that seven of its inmates were burned to death before they could be reached. The oil used in the lamp was tested, and found to flash at eighty-eight degrees Fahrenheit. We need hardly say

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

that the sale of such oil in most American communities is forbidden by law, while shops in dwelling-houses are guarded, in our large cities, in such a way that an accident of this kind would hardly be possible.

THE last *Bulletin* of the Department of Labor contains an interesting article, by Mr. Henry J. Harris, on the present condition of the smaller industries in Germany. It is hardly necessary to say that statistical treatises on social and economical subjects are abundant in Germany, and the figures which Mr. Harris uses are well chosen and significant. We have heard a great deal of late years about the economical revolution which would be effected by the supply of cheap motive power to small establishments, as distinguished from the great factories which have become characteristic of modern industry; and, in France, the characteristic French care for the individual citizen has led to the introduction, under the favor of the Government, of various schemes for the distribution of power in small quantities, by means of compressed air or otherwise. However this system may have succeeded in France, it has not made much progress in Germany, where the number of small establishments using motive power is insignificant, and tends rather to diminish than to increase. The substitution of small motive-power units for large ones has, indeed, progressed rapidly, but it is not the family workshops which have created the demand for small motors, but the great factories, which have found that the cost of motive power is so small an item in their expense-account that it is more economical, in the end, to use a considerable number of engines or motors, working independently of each other, than to depend upon one large central power-producer, the stoppage of which involves the cessation of operations in the whole establishment. So far is this new theory carried in Germany that in a great textile factory at Chemnitz every loom is driven by an independent motor. Such improvements in factory management do not, however, tend to throw work from the factory to the domestic workrooms, but the contrary. Every economy in production on a large scale makes competition more difficult for the small operator, and the little home establishments, of the mediæval pattern, steadily diminish. Undoubtedly, the disadvantages of the change are, to a great extent, offset by the enormous improvements which have taken place in modern factory life; and those who mourn the disappearance of the old German workshop, where the master and the apprentices worked side by side in producing charming articles of everyday use, and where the most intelligent and industrious apprentice usually, at least in the story-books, married the master's daughter, and became, in his turn, rich and respected, may console themselves in part by comparing the German factory-village of forty years ago, filthy, degraded and neglected, with that of the present day, orderly, well policed, and provided with numberless advantages, in the way of schools, hospitals, nurseries, churches, model dwellings, playgrounds and parks, which the last generation hardly dreamed of. It is true that much still remains to be done in this direction, but it now seems not impossible that the factory system, through careful regulation by law, and, still more, through the intelligent charity of the owners and managers of great establishments, may become the most powerful of all agents in the elevation of a large portion of the community.

OLD people in Massachusetts can still remember that the early cotton factories in Lowell were intended, not only to earn dividends for their owners, but to promote the intellectual and moral good of those employed in them. It was then thought that the management of a loom was quite compatible with refinement and modesty, and the farmers' daughters from the neighborhood, who formed the greater part of the operatives, were properly cared for, and, according to their own account, were happy and respected. Those who had a taste for literature united in composing and publishing, in their leisure moments, a very creditable little periodical, called, we think, the *Lowell Offering*, copies of which are still to be seen in public and private libraries, and very many of the operatives, both men and women, reached, later, high social standing. Somewhere in our own family is preserved a silver pitcher, presented to a cotton-mill manager by his grateful employés; and the relations between operatives and managers were generally pleasant and creditable to both sides. In the course of years, competition on one side, and socialistic eloquence on the other, brought a change in the conditions. The cotton-mill managers thought it necessary, in order to reduce cost of production, to lower wages to a point which would attract only the most destitute and ignorant operatives. It is doubtful now whether this was not a mistake; but it became the accepted policy, and the Anglo-Saxon farmers' sons and daughters were replaced by French Canadians, Hungarians, Poles and Portuguese, among whom the agitators proclaimed that capital was robbery. Although the Lowell mills have always been managed in such a way as to suffer comparatively little from labor troubles, they could not escape altogether the consequences of the alliance of ignorance, poverty and agitation, and, in a mitigated form, they share the common condition of textile and other factories employing cheap labor, in an absence of anything like the old sympathy between employers and employed. Whether this will ever return is, here as all over the civilized world, a question of great importance. It is possible that the improvement of machinery, and a demand for finer goods, may raise the standard of intelligence necessary in operatives, and with it the capacity for appreciating and reciprocating good feeling on the part of the employers, and it is at least an encouragement to think that whatever is done to elevate the character of factory operatives throughout the world will not have to be repeated for a lower class, the operatives themselves being now the lowest in scale among citizens of civilized communities, instead of being, as in mediæval times, representatives of the middle class, with a great mass of serfs and proletarians below them.

LE GENIE CIVIL publishes an interesting essay on trusts and other industrial combinations, in America and elsewhere. Concerning the American variety it quotes Mr. Havemeyer's opinion, that "the tariff is the mother of trusts," and mentions the example of the wire-nail trust, which sold in Hamburg for twenty dollars a ton the nails that it was selling at the same time in Baltimore for more than fifty dollars a ton, to show the effect of combination to monopolize a highly-protected domestic market. At the same time, it believes that trusts of a certain kind are useful, and may prosper, even in countries without a protective tariff. Thus, an association has existed in Germany for several years, among the coal-mine owners of the Westphalian basin, to regulate the output of the mines, as well as to fix prices. Naturally, in a country surrounded by other coal-producing regions, it would be impossible, without the aid of a protective tariff, to maintain exorbitant prices, and the operations of the association, or "cartell," as it is called, have tended to the advantage of consumers, by preventing violent fluctuations, while they have benefited the community by avoiding waste, at the mines, of the precious mineral which we are so rapidly exhausting. The Westphalian cartell is authorized and protected by law, and the Government itself is a partner in it, through certain mines belonging to the Government, which are members of the association. Under its constitution, the affairs of the mines are regulated by a Commission, chosen by the associated mine-owners. The Commission decides upon the amount of coal to be mined every year, and assigns to each mine its proportion of the total to be produced. If any mine produces more than its proportion, it is fined a certain sum for every ton in excess, while a certain indemnity is paid for the production of less than the proportion assigned. All the mines in the association are obliged to sell their coal to the cartell, and agree not to sell to any one else; and the Commission of the cartell sells again. As the Commission always knows how much coal it will have to sell, and how much it will cost, it can fix its prices without adding any margin for contingencies, and its customers can do the same, to their great advantage. The result of the system, as administered by the Commission, has been that, within the last six years, the difference between the highest and the lowest price paid for Westphalian coal has been only about twenty-two per cent; while, before the formation of the cartell, a variation of two hundred per cent had taken place within fourteen months, and the average price for four years before the formation of the cartell was considerably higher than for the four years following its complete establishment.

A PATENT has been taken out in Germany for a kind of brick, made with porous concrete, saturated with tar, for building into walls, in place of the ordinary wood brick, for nailing grounds and finish. In this country, where wood bricks, when exposed, in winter, to the drying atmosphere from furnaces or steam, soon become loose, grounds and nailing-strips are usually secured to the walls by nails, driven into the joints of the brickwork; and this method answers well; but, occasionally, a more secure nailing is required, and for this purpose the concrete and tar bricks seem likely to be well adapted.

THE GENIUS OF MICHAEL ANGELO.[1]

EMERSON says that when we learn the age of the ornaments on our iron fences, we shall think very well of the first men or ill of the latest.

We are constantly reminded, by religion and by the fatality of our own existence, of the eternity which lies before us; we recall too seldom the eternity of the past which becomes unknown. The architect should be brother to the astronomer, who computes time in such great epochs that the age of the earth is to him of little significance; to the geologist, who sees in the present but one layer superimposed upon innumerable other strata; then he shall learn to set a proper equilibrium to his thoughts, — to see the art of the present in proper relation to that of the past.

The spirit of novelty is ever present with its illusions, not because there are so many new things in the world, but because we ourselves are so novel to our surroundings. We know so little concerning the past of the earth wherein we live that we are prone to regard every recurring experience as being something new and original, but there is indeed not much that is original about us outside of the fact that we are new in our own sphere of existence, and may have power to impress our personality somewhat upon prevalent ideas which are the heritage of all.

Much is said of Nature and of fidelity to Nature in Art. We are, in fact, part and parcel of one creation and may safely assume that we can be original only in the same degree and in the same manner in which Nature herself is original. Human understanding is thought to be the culmination of nature; human intelligence may be more subtile and more comprehensive than other demonstrations of natural laws, yet it is not possible for us to elevate ourselves beyond, nor to separate ourselves from, other forces which move the visible universe.

Let us inquire, How is Nature original? Nature never produces a new form where an old one will answer her purpose. She sometimes makes new leaves, she sometimes creates new flowers and new fruit, but her processes are long and tedious; she clings to old forms long after they have ceased to be of service to her. If she is hurried in her interminable processes she produces freaks. Her oaks are always oaks; she may transpose them from soil to soil, and from clime to clime, until they have changed their forms, until they have altered the shape of their leaves, but she will never come to a period when they will bear other seeds than acorns. And yet new forms and new species she does produce out of the long periods of time at her disposal; also because she once labored under less restriction on this globe than she does at present. Earth, like ourselves, was once young and pliable, before she became set in the rigid mould of the present.

Cultivate the form of Nature if you will; change her daisy into a chrysanthemum; eliminate the seeds from the apple and orange; employ your art to shorten the length of her periods; to compress her epochs into seasons, her years into days and, yet, she will refuse to depart from fundamental types. Let us, then, turn to Nature for instruction, we who would invent new styles and new orders of architecture. She will offer us little encouragement, but she may set us in the right path. She may impart to us some of her sincerity, some of her unconscious power, some of the humility which is her strength. Let us not distrust the methods of Nature; she copies without hesitation; ofttimes in a perfunctory manner. God above us is Himself Prime Copyist when He rolls His nebula together to form new worlds.

In the town of Lancaster, Ky., there is a court-house erected at a period when vernacular building was at lowest ebb. The architect of the structure may have been a carpenter who knew nothing of the architecture of books. There is an arcade across the front of the building upon which he chiefly exercised the resources of his calling. He knew nothing of orders and arches, or of Vignola. He did not even take time to study orders from the Grecian example at Richmond Court-house, fifteen miles distant; he, in fact, flourished at a time when columns and entablatures were not in proper vogue. He made his piers exactly as he had seen the most recent examples of wooden columns in his own native village; somewhat more massive, it is true, in deference to the material employed, but square and with chamfered corners, after the manner of those with which he was familiar; he provided them with bases like those of his prototypes; he embellished them with capitals, not at the top of the shafts, but at the spring of the spandrels or braces; he produced his stone spandrels in direct imitation of those of the wooden verandas; he then set his architraves from column to column after the immemorial fashion. Now, I consider that man to have been a genius; I make this assertion in all confidence because he possessed the prime element of genius, sincerity. He but needed further opportunity; had he been permitted in like fashion to have builded for a sufficient length of time, he might have evolved a new style of architecture. For in this manner were the styles of the past brought forth; they were creations of times and circumstances rather than of conscious or continued effort. They are the outgrowth of the ages which fostered them, and not inventions of individual minds.

But I have mentioned Michael Angelo, and what may this digression of the village carpenter have to do with that most eminent master? They do not, indeed, stand so very far apart; there is no missing link to the chain which connects them one to the other. Michael Angelo is omnipresent in his personality. He stands amongst the most universal of men that have lived, and as such belongs to all times, to all men, to all things. It is not probable that the village carpenter (assuming him to have been such) was familiar with Vitruvius; Homer and Virgil may have been to him but mere shadows of names; yet I fancy that he must in some degree have been acquainted with Michael Angelo. That supreme genius must in some fashion have been connected with the development of his understanding; in some indescribable manner blended with what intuition of the symbols of art he may have possessed. Special knowledge he may not have acquired, neither of sculpture, neither of painting, certainly not of architecture, to associate with any of these the name of the Great Master. Yet, symbols of art of some sort he must have possessed. These belong to all who have attained the first degree of enlightenment. Vague or definite, mean or exalted, the mind turns instinctively from symbol to symbol. The building suggests the monument, the monument suggests the statue, the statue the painting, the painting the song, the song the instrument. We all of us are architects, sculptors, painters, poets, musicians, in some degree, at some moments of our lives. We all of us have symbols, whether conscious of the fact or not, and in so far as these pertain to modern art they are in some manner associated with Michael Angelo. We will therefore allow our village carpenter to have been, at the moment he set his architraves upon their columns, somewhat inspired and therefore imbued with some measure of the spirit of the Great Master.

On the Italian steamer on board of which I was a passenger from New York to Naples, there was a bright boy, presumably a new apprentice in the art of navigation; his duties were of the menial sort, yet he evidently was not an ignorant lad and may have been at the commencement of some successful career. One day he was employed at painting on deck, and his remarks seemed to amuse those of our company who understood his tongue. "What does he say?" I asked. "He says, 'I am the Michael Angelo to-day,'" responded an Italian. The lad had but reminded us of the vast influence of Michael Angelo over the entire world.

When, shortly after that incident, I saw in Florence the drawings executed by Michael Angelo as a student — first attempts which seemed so near akin to our own primitive essays at drawing — I recalled the boy on the steamer. We are so much alike, with the same human nature after all, the greatest and the least; the difference which separates us one from another is more often in degree of sincerity than in measure of resource. Every one of us is a Michael Angelo to the extent and degree in which he is endowed with faith and that strength of purpose which is not the outgrowth of craft, but the spontaneous sincerity of the soul.

The qualifications of the great artist do not consist in logic, or in any faculty of abstract reason. Art is the spontaneous expression of intuition. Art has always flourished in more intimate relations with religion than with science, insomuch that Faith may be considered as the foundation of Art. Without faith, intelligence may build bridges, railroads, skyscrapers, warehouses, produce scientific marvels, but cannot create architecture, cannot give vital expression to any form of art. If we do not entertain that ideal which is so very near akin to religion, then is the artistic spirit not within us. The intuition of the beautiful may be fostered and cultivated, but cannot be wholly acquired; it must be inborn, and cannot be attained through education, however much education may be necessary to give it form and expression. Therein lies genius, the true and trite reason why geniuses are born, not made; yet, we all of us have some spontaneous sincerity within our souls, and are to some extent geniuses. Art being the heritage of the soul rather than of the mind, we can readily understand how those ages which were less enlightened than our own should have surpassed us in those things which appeal to the emotions and to the feelings. They were believing ages; they were dominated by men who worked through faith. The Great Masters of those times were Dante, Titian, Michael Angelo, giants of truth and sincerity. We may not approach them without adding to the measure of our own faith. We may not write a poem, paint a canvas, conceive a monument, without becoming conscious that the eyes of those masters are resting upon us. They accuse us of hypocrisy, of frivolity, of shallowness, yet they will in no wise discourage us, but add to the measure of our strength. Their faith enables us to understand the elements of truth. If we have not already entered within their influence, we are as yet as little children that have not learned their A B C's.

The entire world has been under the spell of Michael Angelo; his influence has been greater than that of any other man who has given impetus to the development of art in our own times. Three hundred and fifty years have passed, and his greatness has not lessened, neither has any appeared to be his rival since his day. He stands before us a lofty mountain in eminence; he may be compared to Napoleon in the magnitude of his personality. His individuality is in itself more significant to the world than any specific achievement of his skill. He appeared capable of all things; he surpassed other men in the intensity of his faith, the depth of his sincerity, the warmth of his imagination, the fertility of his resource, the measure of his industry. It is interesting to follow every incident of his long and eventful life. He imparts form and color to everything upon which the impress of his gigantic mind is cast. He is not alone the man of imagination, the sculptor, the painter, the architect, but also the skilful engineer, the builder of roads and ramparts, the counsellor of princes, the man who dared confront the

[1] An address by S. E. Desjardins, F. A. I. A., before the Cincinnati Chapter of the American Institute of Architects, May 20, 1902.

Pope, the man of impulses who tolerated no rival; in all things more than other men.

If we conceive of originality as being embraced in individual force and personality, and not in novelty nor in ability to effect unusual combination and achieve striking results, then is Michael Angelo the most original of men. Otherwise he was original in no extraordinary manner; he understood the futility of striving after novel effects and novel forms, the meagreness of all resources, the inadequacy of mere dimensions to produce results. He was adept in device and invention, making more use of these in painting than in architecture, but he fully understood their subordinate purpose, their secondary province in the realm of art.

I restrict my attention chiefly to Michael Angelo in his relation to us as architect. Architecture was to him but one of the many incidents of his long and productive career. It was but late in life, at a period when the labors of most men are drawing to a close, that he began the serious task of the dome of St. Peter's. He did not propose the dome as an original idea, but merely undertook to carry on the work of his predecessors. Even the oft-quoted assertion that he proposed to suspend the Pantheon in mid-air did not originate within his imagination. Bramante had entertained a similar proposition a hundred years before. It is quite certain that St. Peter's would have had a dome had Michael Angelo never been called upon to produce that remarkable culmination of his genius. It is also probable that the dome would have been fully as great and fully as high as the one which was carried into execution. It is also to be conceded that without the Great Master the dome would have exhibited as much invention in conception, and, in all probability, would have been more profuse and elaborate in detail. Rosselini probably embodied a dome in his original scheme submitted to Pope Nicholas; Bramante conceived a grand dome for St. Peter's; Sangallo designed another and more elaborate one. Since the day when Brunelleschi began the great dome of Florence, it had become the dominating idea in architecture; no monumental structure was conceived without the dome. Michael Angelo set about to finish the work already begun: to complete the dome which should exceed all other domes; not in breadth, although it needs must be vast; not in height, although it needs must be lofty; height and breadth the dome must possess, but it must include far more than mere dimensions. He was a Florentine, born within the shadow of the great dome of Florence, while here in Rome he was restricted within limits less in extent than the vast area crowned by the vault of Brunelleschi. Notwithstanding this restriction he made his dome to exceed that of Brunelleschi in all those essentials which embody the conception of greatness, grandeur and simplicity. The dome of Florence which he was to copy and to surpass was vast, grand, lofty, sublime, sombre, ponderous. He embodied in his structure the first of these attributes; he eliminated the last, sombreness and ponderosity. Before him Brunelleschi also had studied the Pantheon at Rome so as to conceive the stupendous idea of suspending the Pantheon in the air and setting it aloft upon lofty piers, but he labored under greater disadvantages than did his successor, and the Pantheon in transformation lost his contour of its vault, the beauty of its proportions. Michael Angelo was equal to the task of overcoming all objections, literally suspending his dome above its vast supports, where it looms in unsurpassable majesty the most notable architectural achievement of modern times. This he accomplished, and, with intuition yet more subtile in simplicity, produced in the exterior structure of the dome a worthy complement of the interior.

The contrast between the dome of Brunelleschi and that of Michael Angelo is the difference between first experiment and final result. In the former we are at once reminded of the ponderous weight set upon the piers, we admire the invention and daring ingenuity of the architect. In the latter we are unconscious of the piers, oblivious of the personality of the architect. The grandeur and majesty of the vault is all-prevailing; it is the true Pantheon in mid-air.

There is no invention, no novelty of form; the same columns, pilasters, capitals, architraves, pediments, which are the heritage of all Italian architects. Nothing new, but the great result, the thing, itself.

This simplicity is characteristic of all of the architectural creations of Michael Angelo. He employed few forms, the most simple motives, the most ordinary types, yet he invests these with individuality they had never yet possessed. The pediment assumes grandiose proportions; the festoon, Titanic magnitude at his hand. To him especially belongs the high segment introduced so effectually in St. Peter's and in St. Mary of the Angels. Neither may we pass without notice the Farnese Palace. Here we find the crowning feature, the great cornice of the Florentine Palace transported to Rome with added dignity and inimitable grandeur.

We arrive at a definition which enables us to understand the distinction between originality and servility, and it embodies in a comprehensive sense the difference between copy and unworthy imitation. The master mind which copies learns to begin where others have left off; knows how to finish where others have begun, and this talent is not within the range of the servile, who begin where circumstance may place them and never attain more than a portion of the success of others who have labored in the same fields before them. If we have learned what our predecessors have acquired and are able to complete anything whatever which they may have left unfinished, then have we achieved success and have accomplished the work of the original minds.

Great men are the product of the places and times which offer them unusual circumstances in which to achieve renown. In order to understand the career of Michael Angelo, we must also learn the history of Florence during the three centuries which preceded his day. We must be familiar with the career of Arnolfo, Giotto, Brunelleschi and a host of others who exerted before him their influence upon the art of Florence.

We turn from Italy and find an illustration of this fact in the works and fame of Shakespeare. We are all familiar with Shakespeare, but we are not sufficiently alive to the fact that Shakespeare might not have been immortal to us had he not been preceded by many who prepared the way for his coming; had he not been surrounded by a hundred other poets and dramatists of no mean genius, of whom his greater genius was the culmination. We may in our own country find an opposite example in the career of Richardson, the greatest architect of our times. He came at the beginning of these things, as it were; not to impress his large individuality on work which others had begun, but to give expression to genius with foreign symbols in a land where there were no established traditions of art. He achieved remarkable success; exhibited great originality and strength of purpose, but exerted no lasting impression upon the architecture of the age. In fact, he left none to complete the work which he himself could do no more than to begin. His forms were alien, his symbols exotic; it would have required greater geniuses than he to have carried out his style to rational development, and this the natural limits of human ability precluded. His works remain to us interesting in themselves, but they will not serve the future as prototypes because they are not in harmony with the spirit of our times. Had Richardson remained in Paris; had some great opportunity like that of the Grand Opera-house come to him, then might he have attained immortality when our more primitive conditions denied him. The right sphere of the great master is at the culmination rather than at the beginning of events.

It may not be within the range of our experience to be great masters; the world has not place for many Michael Angelos; we are obliged to do those things which are set before us to be done, but nevertheless the masters' lesson is given us to learn; the power of discrimination, the distinction between originality and imitation is put to us at all times and under all circumstances. We may all of us have within us some of the spirit of Michael Angelo. We may not have opportunity to build enduring monuments and domes, but it is necessary that we should in some measure have the souls of those who build monuments and domes in order to achieve the least success in anything. It is necessary for us to have within us far more than we have opportunity to impart to our work, and we require not mere knowledge of facts, but intuition which gives the mastery over facts. If a man has expended all of his resources in the accomplishment of anything, something will yet be wanting in the result of his effort. His work will not stand in complete entirety, but will, in some measure, be a failure if in its conception or execution he has exhausted the power of his art. This fact cannot be too strongly impressed upon us in this practical age wherein so many are eager to undertake tasks which are beyond their measure. The Great Master was in himself more than his statue of Moses, greater than the allegories of the Sistine Chapel, greater than the dome of St. Peter's. His career was an evidence of supreme power which he could not express in any of the works, and in his old age he poured forth yet more of the inexpressible depth of his nature in verse, for he was a great poet as well as a great sculptor, a great painter and a great architect. In a sonnet to the Supreme Being he voices the universal prayer: —

> "The fetters of my tongue do Thou unbind,
> That I may have the power to sing of Thee
> And sound Thy praises everlastingly."

These words have a familiar sound, and they also serve to remind us that all familiar things have great origin, else they cannot endure long enough to become universal. We feel our spirits expand, we become greater in the presence of so vast a soul, wherein genius is so intimately blended with simplicity. If we study all of the achievements of Michael Angelo we shall find that they are all comprised within primitive elements: sincerity, faith, application. He followed beaten paths of knowledge; he adhered to standards set by others of his own times; he employed invention sparingly; he tried few experiments; he troubled his spirit little concerning originality. The principal lesson of his life is that of application. He studied long, continually and unremittingly; he labored patiently and untiringly. We all of us may do these things. He taught us the important lesson that nothing of permanent value may be attained without long preparation and assiduous preliminary study. He impresses us with the fact that the untutored spirit may not aspire to the work of the trained imagination, the well-stored mind, the skilful hand. We may all of us learn these lessons if we have time and opportunity before us. Cultivate the talent, and the genius will come forth in the well-beaten path, the originality will find new expression. The sum of originality in any one man, even the greatest, is so small as to be of little avail, unless when to the personality of genius is added the considerable heritage of others who have preceded in the same path.

We will place beside the dome of St. Peter's at Rome, the Mole Antonelliana at Turin. The Mole Antonelliana is one of the most original structures of our times. Its conception involved much creative skill, brilliant imagination and constructive ingenuity. There appears to have been no utilitarian problem involved in the planning

of the pile to compel its author in any manner to sacrifice the artistic proportions of the monument. It is unlike any other great building ever projected, and yet I will venture to assert that no one would revert to it as a type from which to conceive any monumental pile. It may be more beautiful than the average skyscraper, which we forgive as the outgrowth of conditions which in themselves are not beautiful, but it is nevertheless an object-lesson of the futility of invention when applied to art.

I will bring in contrast to the above another structure which bears a distinct message to us in these practical days when we find it difficult to associate beauty with utility and are prone to consider that they bear no relation to each other. I refer to the Or St. Michael at Florence. This building was erected as a grain-market and for the storage of grain, and upon it all the guilds of Florence lavished the symbols of their crafts. It was built at a time when the Artist was more powerful than the King, and among such treasures of art was the greatness of Michael Angelo fostered. We have need of such to stand before us and accuse us of our sins of ugliness. If we but strive to make our markets and warehouses as beautiful as the circumstances which surround us will permit, we may come again to a time when men will spend less for sordid desires and more to elevate the spiritual nature of the people.

For if we consider the relation of art to other dominating forces of our age we shall be compelled to admit the fact that we do not live in an age which can be favorable to the presence of great masters. Their spirit is not in our atmosphere, their examples are not among the incentives which actuate the people of our times. But we are not to entertain the idea that the day of art has departed forever. All things are recurrent. All periods pass away but to return. We may arrive at some rare epoch when the soul of sincerity and truth and the spirit of science and investigation shall work hand in hand, and progress in harmony; when some master of the future shall attain greater results than the world has yet conceived. We have at least this consolation: if we are devoted to the beautiful, we are in employ of the highest on earth. We are followers of the truth, and, like St. Christopher of the ancient legend, we serve none but the strongest. The millionaire may buy nothing better than architecture, sculpture and painting with his money. Else wherefore this eagerness for fine houses and rare works of art? Is not Michael Angelo this day greater than the great pope whom he served? If we cannot ourselves be masters we are preparing the way for the masters that will come; and wherein might we find more exalted occupation? When the day of greater things in architecture arises, then shall the architect cease to be primarily a man of affairs and an engineer and shall resume once more his real avocation; he shall once again be artist equal to the task set before him. Think not that the influence under which we live may be sufficiently powerful to change wholly the current of events so that the future shall have nothing in common with the past. Think not that the artistic feeling may ever wholly be crushed from the soul of man; it is too deeply rooted in the very essence of human nature ever to become extinct. We are told that every philosopher is a failed poet, that is, he became a philosopher after he had made the discovery that he could not be a poet. In like manner the ranks of the busy world are filled with men who follow other avocations because they cannot be artists. Else wherefore this universal eagerness for things which appeal to the imagination? Is it the wood and the stone, the brick and the cement which brings us here together? Is it not rather the symbols these things represent which attract us, and do not these seem more beautiful to us than they are in reality because we carry more of the ideal within our souls than we are willing to acknowledge to ourselves and to one another?

Our small measure of effort is all necessary to the future; none of it can be spared. We are all working towards a time when the people shall themselves become possessed of more artistic intuition, more power of discrimination between the beautiful and the deformed; when all men are in themselves artists in some measure or other; when the man shall have conquered his monster of iron and the machine shall have imbibed the spirit of inspiration from the soul of man. At that time the Great Master shall reappear and he shall be surrounded by multitudes of lesser masters.

We may receive the consolation out of the midst of our own inartistic surroundings. Think ye that the streets of Florence never fostered unsightliness, even when the artistic spirit of the age was concentrated in that city? Let us not consider that the circumstances under which we labor are utterly hopeless. We see much deformity in the present, and are prone to magnify the beauty of the past, but we are not to entertain too intimately the idea that the present is devoid of beauty, that the past was freed from the restrictions of our conditions. Nearly all of the past has been wiped out from our remembrance forever; what has remained to us has been the best and most cherished, and to complete our illusion Time has softened the outline of all remnants of the ages to lend them grace. Our remote ancestors, did they not have their daily problems, also? They did not build monuments and temples alone. They must have places to eat and places to drink and places in which to transact business. Are we to suppose that all of these were beautiful and sublime? Perhaps they were beset with no conditions of smoke and steam-engines, no problems of pipes and electric-wires, but compromising conditions and forms of ugliness they surely must have had with them at all times. The familiar history of the past is comprised chiefly in recitation of the affairs of potentates; of war, bloodshed and contentions. Had we but more definite knowledge of the peaceful annals of peoples; had we but clearer record of their customs and domestic habits; could we but enter intimately into their abodes and have introduction into their daily lives, then might we have better understanding of the past and better profit by the experience of others who have solved the same problems before us.

Some sixty miles south of Naples lies the site of the ancient city of Pæstum. Nothing remains within the walls but the ruins of three temples. Within the vast enclosure of the walls are cultivated fields and a few farm-buildings; nothing else but those impressive ruins. At the time of Christ these temples were already five or six hundred years old. During the long existence and in the many vicissitudes of that city, what other buildings, what succession of other buildings, occupied all of the space within these walls? We know, indeed, little whatever concerning them. Temples, theatres, halls, markets, storehouses, dwellings, all structures required to constitute a great city (and human nature was not so very different long ago from what it is at present), such there must have been to supply the wants and customs of so many centuries. They have been utterly wiped off from the face of the earth, and we may reasonably suppose that they were not all worthy objects in their own day. Perhaps the architects of those times complained of lack of opportunity to build monuments and temples very much as we do to-day, since out of so many centuries so few of these remain. We have, in fact, but one clear glimpse into the daily life of the civilization of antiquity, and that is in the object-lesson of the buried city of Pompeii. We know but little of the ordinary buildings of ancient Rome, and out of that vast city of monuments but one structure has been preserved to us intact — the Panthéon. The present alone is ours in which to perform our little parts, and when we learn how Time has preserved to us so little of the past, how may we question the future with any degree of assurance?

We will revert once again to Michael Angelo ere we close. His vast personality is present amongst us in the material sense, in a manner scarcely realized by multitudes of those whose intellectual development has come within the range of his power. The most imposing structure in our land, the dome of the Capitol at Washington, may attribute its beautiful form to a reflex of the supreme genius of the great master, through the intermediary of Christopher Wren and of Walter, it is true, but with salutary presence in our midst; redeemed by noble form from the baseness of the material in which it is embodied and exerting grateful influence upon the architecture of the present day.

PARIS

THE ANNUAL SALONS. — THE SALLE DE LOUIS.

FROM a general visit to the architectural section of the two Salons this year, one brings away this first impression, that there is in particular at the Société Nationale des Beaux-Arts a lot of furniture, and at the Société des Artistes Français many water-colors. Water-colors, which generally deal with motives of architecture, even when little surrounded by plans, façades and technical drawings, can always be held somewhat to represent works of architecture, but furniture rather calls to mind the exhibits of cabinet-makers. This reproach, formulated last year apropos of the Salon of the Société Nationale des Beaux-Arts, is addressed anew to that school of artists who, architects, and talented architects, exhibit hardly anything else than tables, cabinets, chairs, arm-chairs, book-cases and bedsteads. There is exaggeration about this. This is no longer an exhibition of architecture. It is interesting, and I will repeat it again and again, to see an architect compose a bit of furniture and all the accessories of a dwelling of which the *ensemble* will in this way form a unity, adding all the more effect to an attractive harmony. But an isolated bit of furniture without its architectural enframing is a manifestation of art which is more open to criticism. If this piece of furniture is exhibited by a furniture-maker, we do not demand of it any other qualities than those of elegance, satisfactory shape, good taste and solidity. If it is an architect who exhibits this same bit of furniture, we have the right to demand of him a reason for the forms he has adopted, and why he has used this style rather than another, and the best way of enlightening us is to show by the side of the furniture which is the mere accessory the building which is the chief end. Decoration of an isolated room may be interesting, but the neighboring room may afford a contrast which is simply shocking. The tapestry decorators do not hesitate to make a dining room in the Henri II style balance a drawing-room in Louis XV style. The architect ought to show a greater regard for the æsthetics of harmony in the *ensemble* of his work. And this is why a piece of furniture, agreeable enough to see by itself, only has a mediocre interest if it is exhibited by an architect. And the whole story lies in this.

La Société Nationale des Beaux-Arts is essentially modern, and it is in that school of design which it has been agreed to call " L'Art

Nouveau" that it most willingly seeks its inspirations; and this very peculiar art demands above all a greater harmony in its manifestations. Without this it runs the risk of amazing the observer rather than anything else, by underscoring, as it were, an originality which may easily become sheer eccentricity or pretentiousness. Yet I do not take sides for or against the tendencies of L'Art Nouveau. It has already sufficiently proved what there is in it in the way of suppleness, charm and homelikeness, but only on condition that it does not overpass certain limits of allowable fantasy. In architecture it has not yet learned how to get along without dwelling-house, villa and cottage. In this class of work the house of M. Majorelle at Nancy, exhibited by M. Sauvage, architect, is very interesting. Majorelle and Gallé, both citizens of Nancy, have given a great impulse to modern furniture. Both have sought to give it a new style, new forms, and they are among those which exhibit the best taste. M. Sauvage has set himself to preserve unity in the composition of his house, although one perceives his pre-occupation to do something other than that which is ordinary and banal. Bays, up to the present time, have only been square-headed, full-centred or with pointed arches. M. Sauvage has found means of conciliating these three forms by creating a fourth, which evidently lacks frankness, — he snips off the top of a pointed arch and at the point of snipping joins the curved lines of his arch with a horizontal line; but yet in the interiors which he exhibits at the Salon, these new forms do not lack elegance. This is to say that everything in M. Sauvage's work operates to help the harmony of *ensemble* and so makes one pardon certain excesses of the imagination and the constant pre-occupation of the designer to avoid the banal at any price. Here, at least, one feels unity in the style and taste. M. Bracquemond does not satisfy this demand in the decoration undertaken by him for a gallery and billiard-hall. Why does M. Bracquemond, who is an artist of the first class, an engraver of great talent, not content himself with exhibiting his talent in that form of art which has won him his reputation? "Each one his own trade" very wisely declares the proverb. An engraver is not perforce a decorator, nor even an architect. Does M. Bracquemond believe that he has found a new formula for his mantelpiece in ebony and amaranth, composed to support and enframe an alto-relievo by Falguière, carved in wood by Léopold Savine, and painted by himself? Alas! The result is heavy, mournful and ugly. A massive crosspiece of ebony-wood is supported on two uprights of the same wood with impoverished mouldings, and supports the alto-relievo grossly painted in flashy colors. Probably M. Bracquemond ranks among those who lament over the banality of our modern architecture, and the powerlessness of architects to escape from ready-made formulas. Ah! Rather, a hundredfold, let them rest where they are in these ancient formulas than seek a new one such as this.

Ebony has also tempted M. Charpentier, who, not content with being a charming sculptor, energetic or graceful according to the case, has attempted a composition for a grand piano, all in black, massive and heavy, which the moderately decorative paintings of M. Besnard overload rather than enliven. After seeing these things one turns with feelings more inclined to indulgence to the furniture exhibited by architects who, for their part, construct and put their materials together in logical fashion.

Among the works of architecture exhibited by the Société Nationale des Beaux-Arts, we find a very serious study of the church at Cormeilles-en-Parisis by M. A. Besnard, and also certain other projects for churches, of no great interest, which rather strike one with astonishment as one sees them in the midst of the "modern style" furniture which fills the halls. We must mention also the dependencies of the Château de Bois-Chicot by M. Lucien Roy, presented in the shape of photographs and drawings whose skilful rendering makes still more attractive a composition very seriously studied in a pseudo-Renaissance style. M. Plumet, who always exhibits furniture which does not vary much in style, has known how to devise for an apartment-house a very personal and modern note, all the more interesting that it indicates a very rational feeling in the employment of his materials. And this proves that L'Art Nouveau does not exclude the spirit of method.

Architecture, properly so called, is represented in a more complete fashion at the Salon des Artistes Français. I have said there was to be found here an enormous number of water-colors. This is not displeasing, and the public is rather attracted by the picturesque sketches, freely colored by skilful brushes, and finds them more attractive than plans and technical drawings in which it does not find many things to understand. One style of work does not interfere with the other, and there is something for taste of all kinds. So it must be acknowledged that the Salons d'Architecture are much more frequented than formerly, and though one does not meet here the crowds that fill the galleries of painting, one does find in them a certain number of interested visitors.

How can one not but render homage to an effort as considerable as that of M. H. Eustache, who sends a remarkable study of the present condition of the restoration of the Via Sacra at Rome, and the Byzantine edifices of Mistra in Greece. The restoration of the Via Sacra is a learned evocation of ancient architecture, and from its ruins, so picturesque in themselves and having such elements of grandeur, M. Eustache has caused to be born again temples, triumphal arches and basilicas, the arrangement of which on the right and on the left of the Via Sacra forms a very important composition. It is a superb and precious work of archæology which allows one to judge of the importance of the excavations recently made, thanks to which M. Eustache has been able to push to so high a degree the exactitude of his restoration.

M. Eustache's second *envoi* yields in nothing to the first, from the point of view of interest. The town of Mistra, in Greece, has lain in ruins since 1770, but some portion of it has remained still usable. M. Eustache has drawn out a plan of the town and the present condition of the two monasteries of Peribleptos and the Pantanana, the details of whose architecture, sculpture and decoration are presented with skill.

Another work of restoration attracts the attention of artists who are interested in the history of our French architecture. This relates to the Salle de Spectacle, to-day the Théâtre Français, built by Louis in the Palais Royal in 1790. After the fire of March 8, 1900, the reconstrution of the theatre was entrusted to M. J. Guadet, who chose as his assistants his son, Paul Guadet, and one of his pupils, M. Charles Prudent. It is these latter who exhibit at the Salon the interesting restoration of the Salle de Louis. In the works of demolition and reconstruction of the Théâtre Français, MM. Paul Guadet and Prudent uncovered remains of ancient construction imbedded out of sight in later additions, very interesting documents, quite unknown until these discoveries. These investigations which they made have resulted in enabling them to present the first elements of a monograph which will be published after the close of the Salon.

Louis, who had already built the great theatre of Bordeaux, was instructed by the Duke of Orleans to make a study for a new salle de spectacle on a site at the corner of the Rues Richelieu and St. Honoré. The work, begun in 1786, was finished in 1790, but the new theatre, originally intended for the opera, was occupied by a troupe of comedians of the most modest merit, and was leased to the director of the "Variétés Amusantes." It was in 1791 that the Comédie Française, with Talma at its head, was transported thither. In 1799 two architects of medium talent were employed to renovate the Salle de Louis, and they partially destroyed his work. Fontaine, in 1822, was entrusted with the remodelling of the hall, and it is his work, with some slight changes, which was preserved up to 1900, Chabrol, in 1863, having changed almost nothing during his restoration, and M. Guadet in rebuilding the hall in 1900 has made few changes in the auditorium of Fontaine and Chabrol, except so far as concerns the stage.

To-day, we read in the notice which accompanies the study of MM. Guadet and Prudent, there remains nothing of the theatre of Louis except the walls of the façades on the Rues Richelieu and Montpensier, the foundations and some small portions of the circular vestibule. The restored plans of the theatre of Louis are accompanied by a perspective view of the ancient hall, very original and picturesque, and this study [see Illustrations] is certainly one of the curiosities of the Salon of 1902.

There are always the same school *projets*, the same drawings offered in public competition, churches, barracks, town-halls, châteaux and villas. All this would be very monotonous without the water-colors, which are truly superb and skilfully done. Some are sketches more or less picturesque, others are measured drawings of more serious architectural interest. For example, M. Chauvet shows a drawing, quarter full size, of the frescos decorating the old manor-house of Challant at Issogne, in the valley of Aosta in Piedmont. M. Polart shows a drawing of a lavabo attributed to Luca della Robbia, in the Church of Santa Maria Novella in Florence. This artist has marvellously rendered the real aspect of the *faïence*. There are numberless other architectural water-colorists who deserve notice, and of them I will mention at the side of those I have just named MM. Moisand, for his monument to Giovanni at Florence, Ottin, for his old stained-glass window in the church of Ploërmel, Patouillard, Perrin, Rey, Riquet, Santerre, Tauzun and Yperman, the latter, a master in the art of rendering an impression of fresco-paintings. The one which he exhibits this year after Benozzo Gozzoli, in the Campo Santo at Pisa, continues in a marvellous fashion the documents which for a long time this most scrupulous of artists has been collecting.

BOOKS AND PAPERS

SO many people in this country are engaged in one way or another in the arts of decorative composition that this book[2] of Mrs. Vanderpoel's meets a serious want. People who have no practical acquaintance with the subject often say that a decorator must "depend on his eye" for harmonizing his colors, and that without "an eye for color" no one can expect success; but, although this is quite true, the only way in which a mere "eye for color" can be made available is to present to it a series of combinations, and let it choose the best among them. This process takes a long time, and even the most sensitive artist in decoration will find his work immensely facilitated by the possession of a set of rules, deduced from the practice and experience of others, which will show him at a glance the combinations of colors, and the values and proportions of each, which have been found to be most agreeable. With data of this kind to start from, he can plan his scheme at once, so as to

[2] "*Color Problems.*" A Practical Manual for the Lay Student of Color. By Emily Noyes Vanderpoel. New York: Longmans, Green & Co., 91 Fifth Avenue. 1902. Price, $5.00.

include the colors which he selects in their most advantageous values and proportions, without wasting time in blind and unsatisfactory experimenting; and the intention of the present work, which has been carried out, on the whole, very successfully, is to supply an ample quantity of what may be called the raw material of color-harmonies, from which the practitioner can choose what he needs for each particular case, developing, of course, the proper proportion of pink into roses or cherubs, as he may please, and his blues into summer skies or knots of ribbon, but secure in the certainty that, if he keeps the quantities and values of each color within the rule, his work is sure to please. Dr. Christopher Dresser, in his admirable books on Decorative Design, which, curiously enough, Mrs. Vanderpoel does not mention in the extensive bibliography in the Appendix, went over much the same ground, in the same way, and gives a set of exercises for the student which might advantageously supplement the theoretical information in Mrs. Vanderpoel's book; but the latter contains much more matter than the Dresser books, and gives a series of analyses of Chinese, Japanese and other decorative works which are of great value. We regret our inability to say the same of a few plates, purporting to convey "color notes" from nature; but, as they do not seem to relate to anything in the text, and as there are more than a hundred other plates, the student is not obliged to trouble himself about them. In another edition these might, perhaps, be advantageously replaced by plates showing the process of analysis of a piece of Japanese embroidery, or Chinese porcelain, or Moorish tile, by giving the actual pattern in its colors, divided into squares, so that the student can count for himself the number of squares showing the relative area of each color. This is an extremely valuable exercise, and prepares the way for a better understanding of the diagrams which, like those given, simply show the colors in their relative proportions, without any hint of their distribution, and are, in consequence, although easily interpreted by an expert, rather difficult for learners to use.

THIS little book[1] presents very well the examiner's view of brickwork, and, in fact, as the preface tells us, it is intended primarily to cover the City and Guilds of London Institute's examination in the theory and practice of brickwork, as well as that part of the examination of the Board of Education in Building-construction which relates to brickwork; and, after this, to "assist bricklayers in the principles of bonding, and cutting and setting gauged work generally. It does not follow from this that the book is not practical; on the contrary, it would be difficult for the most experienced journeyman bricklayer to write one more practical; and it has the advantage of containing a great many suggestions which are outside the experience of most journeymen, but which will add materially to the resources of a mechanic who finds himself obliged, in actual work, to deal with new or unfamiliar problems.

It is hardly necessary to say that the English methods differ greatly from ours, in bricklaying, as in most other branches of construction. The author, for example, calls English bond, of alternate courses of headers and stretchers, "by far the strongest, and, in the opinion of many, the best in appearance," of all bonds. Among our masons, this bond is regarded as deficient in longitudinal tie, and, where the utmost strength is required, the usual bond in this country consists of one course of headers to five, seven or nine courses of stretchers. Mr. Richards does not mention at all the variety of English bond often used in France, in which the stretchers break joint over those in the second course below. This bond is considered by the French masons superior in strength to the plain English bond, and is certainly more attractive in appearance. It may be observed that American bricklayers, when they speak of "old English bond," always mean what is known in England as "Flemish bond," consisting of alternate headers and stretchers in each course. This bond is often used here in face-work, on account of its old-fashioned "Colonial" effect, but neither it nor the genuine English bond, of alternate courses of headers and stretchers, are ever seen in walls where strength is considered rather than appearance.

After these observations on the different bonds, a very good set of diagrams is given, showing how corners are to be managed in walls of different thicknesses, this not being always an easy problem in walls built with English or Flemish face. Illustrations are given of diagonal and herring-bone bond for the interior of very thick walls, but nothing is said about the best and most useful form of diagonal bond, where face-bricks, which are always laid with us all stretchers, have the corners clipped off, to allow a diagonal header in the backing to be brought nearly out to the face of the wall, resting, of course, on the middle of the stretcher below, and tying the facing course very effectively to the backing. In the same way, chimney-stacks, which, in this country, almost always show stretchers exclusively on the outside, can be well bonded by clipping corners of the withe-bricks, and inserting the ends in the spaces formed by clipping corresponding corners of the outside bricks.

Next, follow some useful directions in regard to forming chimneys, fireplaces and so on, which complete Part I; the succeeding Part being devoted to "gauged work," which, in England, includes all the varieties of cutting and rubbing used in brickwork. Here, again, although this portion of the book is particularly well written and valuable, the English practice differs greatly from ours. Although a good deal of cutting and rubbing of brick is done with us, we are obliged to use hard bricks for the purpose, as the soft English "rubber" bricks will not stand American frosts, and our work is, therefore, rough in appearance, in comparison with the fine and accurate English gauged work; but, as a compensation, we have at command an almost unlimited variety of moulded bricks, which replace advantageously those cut and rubbed to shape. However, in case a cut brick is needed, it is well to know how to cut it accurately, and no book with which we are acquainted gives such careful and clear directions for the purpose.

[1] "*Bricklaying and Brick-cutting.*" By H. W. Richards, Examiner in Brickwork and Masonry to the City and Guilds of London Institute. With over 200 Illustrations. New York and London: Longmans, Green & Co. 1901.

INCRUSTATION ON ST. PAUL'S CATHEDRAL.

IN a recent "Note" in the *Builder* reference was made to the paper read by Mr. E. G. Clayton before the London Chemical Society on the subject of incrustations taken from the Portland-stone balustrade round the base of the dome of St. Paul's Cathedral. Some further consideration of the subject may be of interest.

This balustrade is surmounted by a heavy coping-stone of the same material; much of the surface is greatly "weathered," and is coated by a stratum of a gray or black substance which in some places (especially on the underside of the coping-stone) attains a thickness of three-quarters of an inch. This material, which is brittle and detachable with a knife, has a very rough and irregular surface, is stalagmite in character, and though differing in color, in other respects resembles very closely some boiler deposits, and is easily reduced to a fine gray powder.

ANALYSIS OF THE INCRUSTATION.

Water (lost at 100° C.)	2.06
Water (lost at 150° C.)	22.48
Organic matter	1.10
Lime	26.44
Magnesia	.27
Ferrous-oxide	1.31
Sulphuric-acid (combined)	34.93
Phosphoric-acid	1.02
Carbonic-acid	none
Chlorine	trace
Silica, sand, etc.	10.39
(including combined silicic-acid, SiO_2)	2.33)
	100.00

From the above results the substance is evidently composed chiefly of hydrated sulphate-of-lime associated with some silicious matter and minute particles of carbon in the form of soot. The solvent action exerted by rain charged with sulphurous and sulphuric acid derived from the gases and smoke of innumerable chimneys of the surrounding buildings, has after the lapse of two centuries transformed the original carbonate-of-lime of the Portland-stone into sulphate-of-lime, which, in a more or less soluble condition, has been carried by water action and gradually deposited as calcareous tufa or stalagmite on the underside of the coping-stone.

The practical conclusion to be drawn from this research is very obvious, namely, that buildings in large cities, and especially in manufacturing towns, should not be constructed of limestone, which is readily decomposed by the acids existing in the smoke due to the use of coal largely impregnated with sulphur.

Granite and hard sandstone appear much better adapted for city buildings, but stone of a calcareous character was doubtless originally employed on account of its being more readily, and therefore more economically, worked into suitable shape by the stone-cutter.

JOHN HUGHES.

BUILDING OF H. HACKFELD & CO., LTD., HONOLULU, HAWAII. MR. O. G. TRAPHAGEN, ARCHITECT, HONOLULU, H. T.

MATERIAL of façades: native blue basalt, copper dome, plate-glass windows. Length of frontage on three streets, 423 feet. Interior finish: in general, white quartered oak and mahogany. Counting-room finished in St. Beaume marble, with marble counter fronts and bronze grilles over, and domed frescoed ceiling. Floors of public lobby and corridors are of marble mosaic in elaborate patterns. The building is entirely occupied by the firm for which it was built, and is equipped with private telephone system, conduit system of electric-lighting, three elevators, patent fire-hose reels, fire-escapes on rear, with stand-pipes, patent rolling steel fire-shutters, and the interior construction of floors and partitions is of a form of slow-burning construction.

NOTES & CLIPPINGS

SOME COURT LABOR RULINGS. — The Missouri Supreme Court, sitting *en banc*, handed down an opinion on March 19 declaring that courts of equity have no power to enjoin labor organizations from enforcing boycotts on corporations. The opinion, rendered by Judge Sherwood, affirmed the judgment of a lower court, which had refused the application of the Marx & Haas Jeans Clothing Company, of St. Louis, for an injunction to restrain Anthony Watson and other officers of a local Knights of Labor organization, and a branch of the United Garment-workers of America in that city, from pushing a boycott. Chief Justice Burgess and Judges Brace, Gantt and Marshall concurred in the opinion, and Judge Robinson dissented. Judge Valliant, who heard the case originally when on the Circuit Bench, took no part in hearing the appeal. The opinion handed down by the Court on March 19 says: "If the labor-unions of the State are not permitted to tell the story of their wrongs, or their supposed wrongs, by word of mouth, or with pen and print, and to endeavor to get other persons to aid them by all peaceable means in securing redress of such wrongs, what becomes of free speech?"

ON April 7, Judge Ferris, in a Wilkes Barre court, rendered an important decision in a boycott case. Last June, J. E. Patterson & Co., of that city, refused to grant the demands of their employés for an increase of wages. The Building Trades Council then declared a boycott against the firm. The Court was appealed to for an injunction to prevent the Trades Council from carrying out its threat. A temporary injunction was granted, and to-day Judge Ferris made it permanent. In the course of his opinion the Judge says: "The boycott is destructive to personal liberty and utterly subversive of all social order, all law and all government, and is therefore unlawful."

IN a Philadelphia court Magistrate Rogers recently discharged Director Haddock and Chief Hand, of the Water Bureau, who were charged with misdemeanor in employing stonemasons in the Water Bureau more than 8 hours a day, in violation of the Act of July 26, 1897. "I think the Legislature, when it passed this Act, gave the workingmen a gold brick," said the Magistrate. "The trouble is the Act does not say that a workman may not agree with his employer to work longer than 8 hours if he wants to, and that is, moreover, beyond the power of the Legislature to say. An analysis of the Act fails to show any words which forbid a workman to work more than 8 hours if he wants to, nor an officer of the State or city to employ a workman more than 8 hours with his consent. It is clear that the Act nowhere expressly forbids either of these things."

THE New York Court of Appeals at Albany, on April 1, handed down a decision, affirming the rights of labor-unions to limit their membership and to refuse to work with non-union men. The Court stood four to three on the question. The prevailing opinion was written by Chief Judge Parker, and concurred in by Justices Gray, O'Brien, and Haight. It was dissented from by Judges Bartlett, Martin, and Vann. The plaintiff, the National Protective Association of Steam-Fitters and Helpers, is an incorporated association, consisting of a few members who worked for lower wages than the members of the defendant associations: the Enterprise Association of Steam and Hot-Air Fitters and General Workers and Motive Power of New York City and vicinity. The defendants, through their walking-delegates, insisted that the contractors should not employ the plaintiff's members, but should employ defendant's members, and in several instances caused a strike of all employés working upon a job, with the result that the plaintiff's men were ousted from employment and defendant's members put in their places. In other instances the defendants made threats that they would strike unless the contractor employed defendant's members instead of those of the plaintiff. Justice Truax, at a Special Term, grantedan in junction, restraining the defendants from striking or making threats, which judgment was reversed by the Appellate Division, the Court of Appeals to-day concurring with the Appellate Division. In his opinion Judge Parker says: "They [workingmen] have the right to strike, provided the object is not to gratify malice or inflict injury upon others, but to secure better terms of employment for themselves. A peaceful and orderly strike is not in violation of the law. A body of men having organized for purposes deemed beneficial to themselves have the right, if they feel it is detrimental to interests of their organization, to refuse to work. Their reasons may seem inadequate to others, but if it seems to be in their interest as members of an organization to refuse longer to work, it is their legal right. So long as workmen must assume all the risk of injury that may come to them through the carelessness of co-employés, they have the moral and legal right to say that they will not work with certain men, and the employer must take their dictation or go without their services. . . . A labor organization is endowed with precisely the same legal right as is an individual to threaten to do that which it may lawfully do."

THE Missouri Court of Appeals gave a decision on March 18 in the case of Froelich, a musician, who was expelled from his union because he rode on boycotted street-cars during a strike, and who sought reinstatement by the Courts in his union. The Court held that when a so-called trade-union becomes the tyrannical master and a monopoly, it puts itself beyond the protection of the Courts, and no member of such a union can have a standing in a court of equity. Therefore it could give Froelich no relief from his expulsion, since the musicians' union was a gigantic monopoly.

WHILE presiding at the recent teamsters'-strike hearing, Judge Braley of the Massachusetts Superior Court said: "The Court rules that a combination by these defendants to regulate their own conduct is allowable and is lawful, though others may be indirectly thereby affected, but if upon this evidence, and it is a fact subsequently to be found and determined, they have combined to do injurious acts expressly directed against the plaintiff in this case, by way of intimidation or constraint of persons employed or seeking to be employed by it, that is unlawful. Intimidation, if subsequently it is found as a fact in this case, is not limited to threats of violence or of physical injury to person or property, though it may and is claimed by the plaintiff in its bill to include both. It has a broader signification, and *there also may be a moral intimidation which is illegal.* Patrolling, picketing, 'blocking,' cutting of harnesses and unhitching horses have elements of intimidation, and if these things were done for the purpose of interfering with the business of the plaintiff, a court of equity may grant relief." — *Exchange.*

DORIAN ANTIQUITIES. — The Prussian Knights of St. John, who were formerly in possession of the island of Cos, the modern Istanköi, have contributed three thousand marks towards the cost of the expedition which is about to make excavations in the island, under the leadership of Drs. Herzog and Vosseler, of Tübingen University, and Herr Necht, of Würtemberg, the architect. The expedition is being organized at the instance of the Imperial Berlin Archæological Institute, which has given five thousand marks for the purpose. A portion of any antiquities that may be discovered will be presented to the Royal Museum of Antiquities at Würtemberg, which also contributes to the cost. Prince Albert of Prussia, Grand Master of the Knights of St. John, has given two thousand five hundred marks towards the cost of publishing a report on the expedition. — *Berlin Dispatch London Standard.*

CHRISTIAN ANTIQUITIES IN THE SOUDAN.—Mr. John Ward, F. S. A., writes us from the Savile Club: "We have all heard of the temples and pyramids at Meroë, but few were prepared for the discovery of ruined Christian cities beyond Khartoum. In the beautiful garden of the palace at Khartoum, I saw a huge stone Paschal lamb, of evident Roman structure. Father Ohrwalder told me that this was brought from the ruins of Soba, on the Blue Nile, 25 miles beyond Khartoum, in Gordon's time, and that he knew the place, which abounded with the remains of Christian temples, and was once the centre of a civilized kingdom. Colonel Stanton, Governor of Khartoum, found me a map of the country round Soba, with the ruins laid down. Since then he has visited the ruined temples himself, and is preparing to have them cleared from the sand, and photographed. About 80 miles north of this there are the extensive ruins of another city — Naga — with fine temples of Roman architecture, avenues of lambs, the same as the one at Khartoum, leading up to them. The inscriptions are in hieroglyphs, while the composite capitals of the columns bear the cross, both at Soba and Naga. The lamb at Khartoum has a long hieroglyph text and the cartouche of some ancient king. This inscription had not been observed before I discovered it on the base under the gravel. So far south, Roman work of Christian times with hieroglyphic texts is a novel combination and demands further research. Since I left Khartoum, Colonel Stanton writes me that he learns from the natives that there are many similar ruins spread all over the country, and, 80 miles east of Khartoum, sculptured rocks and inscriptions, while as far away as Darfoor, tidings of ruins of temples reach him." — *London Times.*

BIRD'S-EYE MAPLE. — What is bird's-eye maple? That is a question which just now seems to be baffling not only people who use furniture made of this particular wood, but even woodworkers themselves. In a recent number of a woodworking magazine an article was published which stated that bird's-eye maple was not a peculiar maple, but simply ordinary maple cut in a certain way. In a recent issue of the New York *Sun* that statement is refuted. It is there stated, on the authority of a wood-worker, that bird's-eye maple and curly maple are both cut only from the logs of the rock maple-tree, *Acer saccharinum*, in which a beautiful lustrous grain is produced by the sinuous course of the fibres. This tree is not at all the common hard maple. It is a hard maple, but is full of little gnarls called eyes. Men looking for bird's-eye maple-logs go through the standing timber and pick out the bird's-eye maple-trees, paying for them from $30 to $50 a thousand feet in the woods. Ordinary hard maple-logs are worth only from $6.00 to $7.00 a thousand feet. It would be impossible to cut a piece of veneer with eyes in it from a common hard maple-log, and it would be equally impossible to cut a bird's-eye maple-log, no matter how you cut it, so that it would not show the eyes. — *Exchange.*

NOTES AND CLIPPINGS. 103

IT would take a very strong and nearly unanimous appeal from our subscribers to induce us to continue the form of publication which, during the current quarter, has been given experimentally to our International Edition. We are not satisfied with the practical working of the new method, which seemed to have the promise of many desirable possibilities in its favor, and believe that no mistake will be made in returning at the earliest practicable moment to the original form of publication. From the first issue for July, therefore, subscribers to the International Edition will again receive their copy in its familiar blue-covered weekly form.

THE present fashion, we might almost call it a craze, for syndicate building, has much in common with the rage for coöperative apartments which seized New York twenty years ago. At that time, the apartment, or "French flat," had been newly imported from Boston, where it was popular long before it occurred to the New Yorkers that fashionable people could live in anything but a separate dwelling-house, and the new idea was, as usual, dressed in appropriate costume for local acceptance. As an apartment-house on Fifth or Madison Avenue was a much more expensive affair than the modest Hotel Hamilton, or Hotel Agassiz, or Hotel Kempton, which housed the good society of Boston, it was necessary to devise unusual means of financing such an enterprise, and a special Act of the New York Legislature was passed, to enable people to hold a portion of real-estate separated from neighboring portions by horizontal, as well as vertical, divisions. In point of fact, this law was not much used, the device of vesting the title to the structure in a stock-company, ownership of shares in which carried with it the right to occupancy of a certain portion of it, being found simpler. Such stock-companies multiplied, and were, for a time, very successful, a score or more of large houses having been erected in this way. It was the ordinary practice to mortgage the property to about sixty or sixty-five per cent of its value, so that a stockholder, in paying for his stock, took it subject to a lien to at least an equal amount. This circumstance led, perhaps, to the decline of the system. Naturally, the mortgage interest on property of the kind, and the expense of maintenance, always heavy in a first-class apartment-house, required a large income, which was usually provided for by reserving a portion of the apartments in the building to be rented to persons not owning stock; and if tenants could not be found for these apartments, the stockholders had to make up the deficiency. With some of the houses, unfavorably situated, or unattractive in other ways, this state of affairs was not long in coming to pass, and, after a few years of struggling, the mortgages were foreclosed, of course cutting off the interest of all the stockholders. The mortgagees, on assuming control of the property, naturally took what they could get in the way of rent of the apartments, and the competition of the foreclosed houses still further increased the perplexities of the owners of the solvent ones. Now, although there are no more foreclosures, and the better-managed houses are still occupied by the successors of the original stockholders, or by their sub-tenants, no coöperative apartments have been built for many years, and no more are likely to be built, at least in New York.

WHETHER the fashion of syndicate office-building will have a similar career remains to be seen, but there are many reasons why it is desirable to be cautious in following it. As real-estate men know, the office population is very fluctuating. When business is brisk, and new enterprises numerous, offices are in demand; but after a panic, when everybody imagines that no revival of speculation is possible, the promoters of new schemes disappear, leaving their offices vacant. At the same time, the expenses of maintenance continue, and many an office-building has shown, at certain times, a very small margin of income over expenditure. For well-situated and conservatively managed buildings, the chances would always be in favor of a small return on the investment, even in the worst times; but, for those situated at a distance from the business centre, heavily mortgaged and cheaply built, it is quite conceivable that there might come a time when repairs, expenses and mortgage-interest would more than consume the income from rents. Then the troubles of the certificate-holders would begin. The wiser ones would undoubtedly sell their interest at the first sign of danger, preferring to take a small loss, rather than risk a greater one, and those who were left would have to meet the deficiency. It is said that in syndicates of this kind, which are virtually partnerships, the law makes each certificate-holder individually liable for all the partnership debts, and this consideration, while it should be encouraging to the mortgagees, is not likely, in time of distress, to please the richer certificate-holders, and foreclosure would, of course, cut off all subordinate interests in the property, even if it did not leave a deficit to be paid by certificate-holders in addition to the loss of their investment. So far, there has been little trouble of the kind. A few office-buildings, injudiciously financed, have been sold under foreclosure, but the better class have prospered, and their managers, we hope, have been wise enough to lay up a reserve against contingencies.

THE so-called McCreary Bill, authorizing a Commission to prepare plans, and a report on site and design, for the proposed memorial to Abraham Lincoln in Washington, has been passed by the House of Representatives. The members of the Commission thus authorized have been already selected, and have agreed to recommend the site contemplated in the Burnham-McKim-Olmsted general plan for the improvement of Washington, at the intersection of a line drawn through the centre of the Capitol and the Washington Monument with the north bank of the Potomac. In this position, the Lincoln Memorial will not only add immensely to the effect of the Washington Monument, which is now out of relation with anything else, but will serve as an introduction to the bridge which it is proposed to build from this point to Arlington, on the Virginia side. What will be the character of the Memorial is not yet decided, but several suggestions have been considered, and it is hoped that a decision may be made very soon, so that the cornerstone of the structure may be laid on the occasion of the meeting of the Grand Army of the Republic in Washington in the autumn.

EVERY one will regret the last misfortune which has attended the excavation in the Park Avenue section of the New York subway, and is likely to prove fatal to the brave and able contractor for the work, Major Shaler. It will be remembered that, soon after work on this section was begun, a collision took place in the New York Central railway-tunnel near by, by which nineteen persons were killed, and thirty-six injured. Nineteen days later, a quantity of dynamite, stored for use in the work, exploded, nearly destroying the Murray Hill Hotel, killing six persons, and injuring about ninety others. Less than four weeks afterwards occurred the fire in the Seventy-first Regiment Armory and the Park Avenue Hotel, close to the opening of the tunnel, by which seventeen persons were killed, and work on the tunnel greatly interfered with; and, four weeks later still, a slip of the rock excavation damaged four houses on Park Avenue to the amount of about one hundred

Entered at the Post-Office at Boston as second-class matter

thousand dollars. It is said that Major Shaler, as contractor, was financially ruined by the dynamite explosion and the giving way of the ledge, but he bravely persevered with the work until, a few days ago, while standing in the excavation with the engineers of the Rapid Transit Commission, he was struck by a stone falling from the roof of the tunnel, forty-five feet above him, his skull fractured, and his back seriously injured, so that paralysis has set in, and it is believed that he cannot recover.

TWO elevators, crowded with people, fell recently in New York, fortunately without fatal consequences. In one case, twenty-two men and three girls crowded into the elevator of a clothing-factory. The weight seems to have been too much for the machinery, for, although the ropes did not break, the car descended so rapidly as to tear away the iron gates at the landings, striking the bottom of the shaft with such force as to injure seriously one man and a little girl of eleven, and cut or bruise about a dozen others. In the second case, an elevator in Macy's department-store, carrying a large number of persons, fell from the third story to the cellar. Eight or more of the passengers were injured, but none very seriously. In neither case is anything known, as yet, of the cause of the accident.

THE *Builder* gives a report of a discourse on the "Origin and Symbolism of Church Ornaments," delivered not long ago in London, before the Church Crafts League, which suggests the idea that a book on this subject, treated in the modern critical spirit, and with the aid of modern archæological knowledge, might be extremely useful, not merely in elucidating a subject of real importance, but in dissipating the clouds of sanctimonious absurdity by which it has been surrounded by the people who find in their own illuminated intelligence the explanation of the symbolism which they profess to discover everywhere. Of inspired expounders of this class there seems to be no end, and the incalculable mischief that they do to rational religion might perhaps be better counteracted by a book, written with real learning, and decent respect for historical truth, than in any other way. Of course, the foundation of all modern works on religious symbolism is the book of Durandus, but the worthy Bishop of Mende, if he was too good a Christian to presume to find in his own moral consciousness the explanation of the sacred mysteries, was very credulous, and lacked the wider and more exact knowledge of antiquity, and of ecclesiastical history, which we now possess; so that the subject might very well be treated as one altogether new. As one of the elementary questions for discussion might be mentioned that of the orientation of churches, which, although certainly as practical a subject as history or architectural ecclesiology affords, is in a state of almost hopeless confusion. We know the facts, that the churches of northern Europe, for at least fifteen centuries, have almost invariably been planned with the altar at the east end, and that the feeling in favor of this disposition is still very strong among the races of Germanic descent, while the churches of Italy, the cradle of Christianity, show an uncertain orientation, the altar being quite as frequently at the west as at the east end; and we know, again, that many of the early Greek temples had their sanctuary at the west, their principal door opening toward the east; while the entrance-doors of the Pyramids of Egypt open toward the north; but what is the explanation of all these dispositions, or whether they have any connection with each other, remains to be discovered. The modern view, that the early Greek temples were devoted to a modified and poetic form of sun-worship, and that the orientation was such that the first rays of the sun, on the morning of the longest day in the year, fell, through the open door of the temple, upon the statue of the god at the other end, is both reasonable and scientific, and investigation and inference, of the kind which has led to this explanation of the orientation of the Sicilian and Greek temples, might be applied to other religious traditions with great profit. In the same way, the inclination and direction of the entrances to the Pyramids are such that, when they were built, the North Star could be seen at all times from them, and this circumstance at least suggests interesting possibilities in connection with the elucidation of Egyptian history. On the other hand, when we come to Christian churches, we fall at once into a fog of ignorant assumption. We are told that the Christians put their altars in the east, because the heathen had theirs in the west; a theory which loses, to say the least, much of its force in view of the circumstance that the largest and oldest Christian churches have also their altars in the west. We have also been told, with some probability, that, as the ancient inhabitants of northern Europe were originally sun-worshippers, they were accustomed, in their open-air ceremonies, to bow down to the rising sun, which they saw, naturally, in the east; and that, in consequence, after they became converted to Christianity, they found it more consonant with their inherited religious habits to worship their new Divinity also with their faces turned toward the east. This hypothesis is open to various objections. While it is true that the ancient inhabitants of Europe were probably sun-worshippers, they were quite as much so in the South as in the North. In fact, some of the peculiar rites of sun, or, at least, of fire worship are practised to this day in the Pyrenees, as well as in the remote parts of Brittany, and, more particularly, in Sardinia; yet in none of these regions has the eastward orientation of Christian churches ever been much regarded. Moreover, even if the Christian missionaries, who regarded the heathen gods as demons, had been willing to preserve the heathen disposition of religious structures, merely substituting the Cross for the grinning image of Thor or Loki, which is extremely unlikely, it remains to be explained how the sun-worshippers could have accepted, as a substitute for an enclosure open to the rays of the rising sun, a building which often had not even a window to the eastward, and from which, with the curious, and possibly significant, exception of England, the sun at early morning could not be seen at all.

IN regard to many other details of church arrangement there is the same need of common-sense discussion. The lecturer before the Church Crafts League informed his audience, as a specimen of the way in which "the highest thoughts" were expressed by symbols, that "Going back to the early Egyptians, they found the crocodile deified, and when they inquired why, they found the crocodile could see through the muddy waters of the Nile, and was a tongueless animal, and consequently it was taken as symbolic of the all-seeing eye of God and the voiceless God." How the distinguished canon explained, on these principles, the symbolism of the cat, which was deified by the Egyptians at least equally with the crocodile; or how he made his interpretation of the symbolism of the crocodile fit the circumstance that the animal, if it has no tongue, has a very loud voice, while its capacity for seeing through muddy water is by no means proved, we will not undertake to say; but the lover of truth, in psychological as well as historical science, is not likely to derive much edification from such discourse. Coming down to matters architectural, the distinguished lecturer informed his audience that the chancel-screen was "symbolic of the drawing back of the veil," and, "therefore," "in the early days the screens became the finest objects of art in the cathedrals." As a matter of fact, in "the early days" of the Church there were no chancel-screens, and the cathedrals of the most ancient foundation, which might be supposed to retain most fully any symbolical traditions, have never had any. On the contrary, the high screen peculiar to the Northern churches, in all probability, was originally erected to protect the Benedictine missionaries during service from assault on the part of the more zealous heathen in the half-converted congregation; and its subsequent development as an ornamental feature simply followed the general artistic development of church architecture. It may be observed that ecclesiastics, although they seem to think that symbolic mysticism is good for the laity, pay very little attention to it themselves, and the slaughter of a priest at the altar, which was by no means an infrequent incident of the conversion of the Northern tribes, was far more likely to have suggested the building of a stout fence across the church than any consideration of "veils." Even the reverend lecturer himself showed a little of the utilitarian spirit which, fortunately for their flocks, is really more congenial than mysticism to the clerical mind, by suggesting that the ancient Hebrews, although they were "of a highly poetic nature," in his opinion, used incense "as a disinfectant." The idea that incense could be advantageously replaced by carbolic acid is one which will strike a good many people as novel, if not highly poetical.

THE friends of M. Bénard, the distinguished winner of the competition for the buildings for the University of California, who, as our readers know, resigned the commission, on account of the difficulty of attending to his duties in Paris and California at the same time, will be interested to learn that he has been appointed Professor of Elementary Architecture in the School of Fine-Arts, in place of M. Coquart, deceased.

NOTES ON IRON AND STEEL CONSTRUCTION.[1]—VIII.

HAVING decided upon the structural rolled shapes that are to be used in the column, and the best arrangement for them in order to secure an economical column-section, and one that is readily utilized for rigid girder and beam connections, it is necessary to consider the design for the base of the

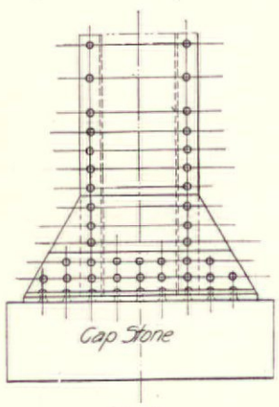

Fig. 51.

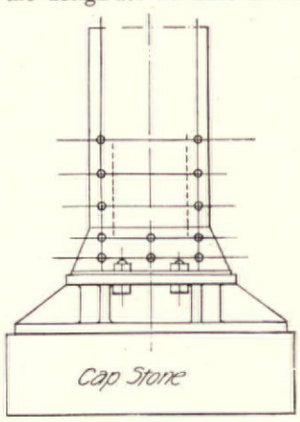

Fig. 52.

column, the manner in which the floor-beams and girders are supported, and the spacing of the rivets, that the rolled shapes and plates may be adequately secured to each other so as to act in unison under the load.

The base of a structural-steel column may rest either directly upon the top of the capstone of the foundation-pier, or upon a cast-iron base-plate. In any case, the end of the column must have ample bearing-area, and must be reënforced so that there is no danger of failure by the plates and rolled shapes separating or spreading at the ends.

When the column rests directly upon the capstone, the form of base shown in Figure 51 is usually adopted, and consists of a heavy bearing-plate, from $\frac{5}{8}$ inch to 1 inch in thickness, held securely to the end of the columns with angle and gusset plates, as designated, the rivets holding the plate to the column being countersunk and chipped on the under side so that a level bearing may be obtained for the column upon the capstone.

Where the structural-steel column depends upon a cast-iron base for the distribution of the pressure upon the capstone or pier, the design shown in Figure 52 is frequently adopted. It will be noted in this figure that the column is held to the cast-iron base with the necessary bolts through angle clips, riveted to the end of the column. It is not usual, however, to secure a cast-iron base to the capstone or pier by anchor-bolts, for this practice is now considered entirely unnecessary. Where a column rests in this manner upon a cast-iron base it is necessary to face both the top of the base and the end of the column. It is not, however, usual to rivet to the bottom of such columns a steel-plate bearing between the end of the columns and the top of the cast-iron base-plate; the usual column is faced across after the clips have been put in place, the ends of the columns, and clips as well, being finished. An exception, however, to this occurs with the Phœnix columns, as shown in Figure 53. Here the end of the column only bears upon the base-plate, the clips being kept $\frac{1}{8}$ inch or $\frac{1}{4}$ inch back from the end of the column, so that none of the bearing is transmitted through the rivets holding them. The end of such a column requires little reënforcement, and the clips add nothing to its bearing-strength; besides, the difficulty in finishing the clips, as well as the end of the column, would preclude such work being done. The elevation in the figure shows the clips kept back from the end of the column, and clear of the face of the base-plate.

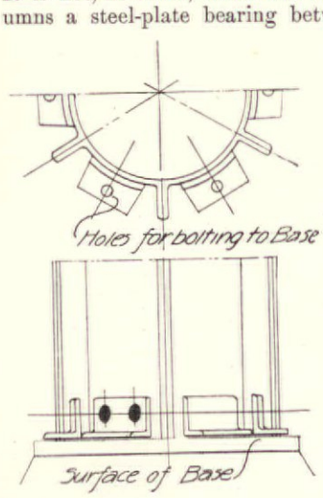

Fig. 53.

The floor-beams may be secured to the column in many ways, and great care and ingenuity have been exercised in the design of these connections. It has become the practice, however, to endeavor to provide bearings for these beams upon a bracket riveted to the column, and to make no attempt to support the beams by the web and through the shear of rivets

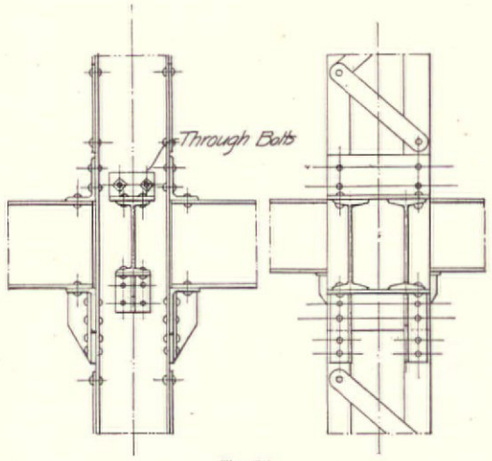

Fig. 54.

through the web and angle-clips riveted to the column. The most practical connection, and one generally used, is designated in Figures 54 and 55; in the former is shown the principal girder and beam connections to a channel-bar column, while in the latter is designated the same character of floor-beam connections to a Z-bar column. The brackets supporting the column are made of angle-iron reënforced by a web, likewise formed of angles; the beams are held in place, top and bottom, by rivets through angle clips. This form of connection is most rigid, as it gives a framing which provides considerable resistance against lateral motion and offers the greatest possible leverage for this resistance where knees or other forms of wind-bracing are not used.

This connection is far preferable to that shown in Figure 56, for while the latter has the advantage of being economical, it certainly offers less rigidity to lateral motion.

Outside columns of buildings must have specially designed connections for the support of the curtain-walls. These connections are usually quite complicated, as, besides providing support for the curtain-walls, there is usually required adjacent thereto a connection for the floor-girders. The usual and simplest connection is designated in Figure 57.

Besides the design of the beam-connections, the splicing of the columns in the tiers of the several stories requires careful consideration. Owing to the difficulty in shipment and handling, and also to the fact that structural shapes are limited in length, the columns must be spliced at several places throughout their length from foundation to roof. Numerous splices should be avoided, and structural-steel columns should be designed of as great a length as convenience in shipment and

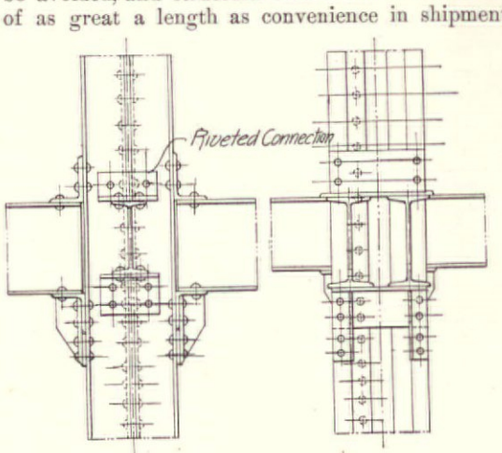

Fig. 55.

erection will allow. Where it is possible, a column should run through several stories without a splice, and the splices upon the different sets of columns should break joints. Where it is necessary to splice the column it is usual to make the connection between the upper and lower column close to a beam-connection, in order to facilitate the erection of the column above

[1] Continued from No. 1379, page 70.

and the riveting of the splice. In fact, the splice-plates often carry the beam-connections as designated in Figure 58. The ends of the abutting columns should be milled or faced, and it is usual to place between them a plinth-plate, as designated at *a* in Figure 58; the flat sides of a column are held between two splice or fish plates which extend past the joint for from 18 to

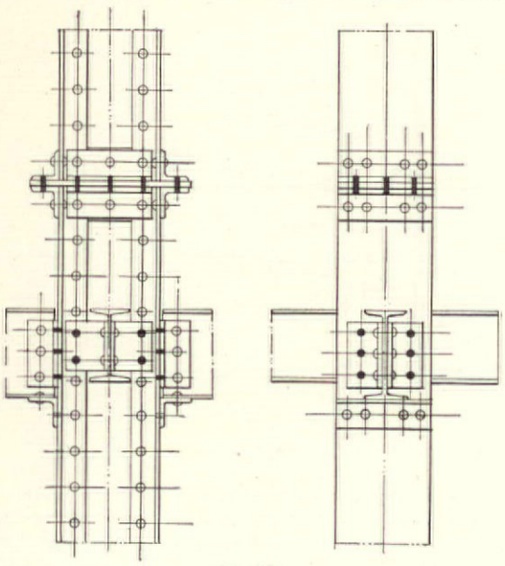

Fig. 56.

24 inches upon each column. These plates are securely riveted, usually to the lower column in the shop and necessarily to the upper column in the field. In angle columns the plinth-plate and connecting angles are sometimes omitted, and instead of the side-splice plates web-splice plates are used. This makes a very rigid connection, but it is not frequently employed.

In spacing the rivets throughout the length of the column, the rivets holding together the several rolled shapes forming the shaft of the column should be spaced at the minimum pitch for a distance of from 2 to 3 feet from the bottom and adjacent to the floor-beam and girder connections; through the balance of the shaft of the column they may be spaced the maximum distance for compression-members, namely sixteen times the thickness of the thinnest outside plate, provided such a thickness does not exceed 6 inches.

At the beam and girder connections the brackets should be

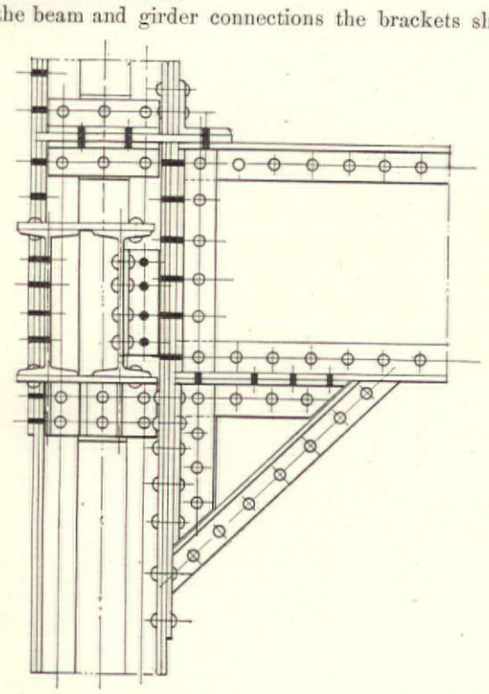

Fig. 57.

held to the shaft of the column with sufficient rivets so that their safe allowable shearing-strength will take care of the reactions at the ends of the girders. In designing connections a rivet should never be considered in tension. Where a connection requires by its design such a means of securing a plate, angle or clips, bolts should always be used. The reason for this is that very little dependence can be placed upon the heads of rivets, especially when driven in the field, as they are often driven at a low heat and are partially crystallized, in consequence, where the shank joins the head.

If there are any bending-moments upon gusset-plates forming an important member of a connection, they should be carefully studied and provided for by riveting or bolting. The rivets in splice-plates are spaced from $2\frac{1}{2}$-inch to $3\frac{1}{2}$-inch centres. The principal consideration in designing the rivet-spacing in such connections is to provide sufficient resistance in the rivets to equal the strength of the net section of the plate.

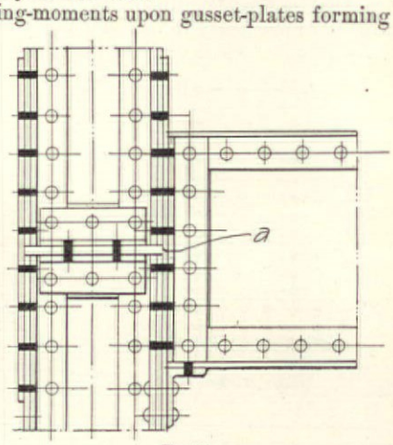

Fig. 58.

There is no more important matter in the design of tall buildings, outside of the foundations, than the lateral or wind bracing. It is a well-conceded fact that the floor-systems and the usual fireproof partitions as constructed in high buildings do not provide adequate lateral resistance against vibration of moving machinery, jars and shocks from accidental causes, and particularly from the wind-pressure upon the large area which the sides of such buildings offer. The different methods of bracing a building of the skeleton-construction type are practically five, and they may be enumerated as follows: —

First. — The connections of the floor-beams and girders to the columns may be so rigid as to provide all of the stiffness required. Rigidity is obtained in such connections when the floor-principals are of deep beams or plate-girders, securely

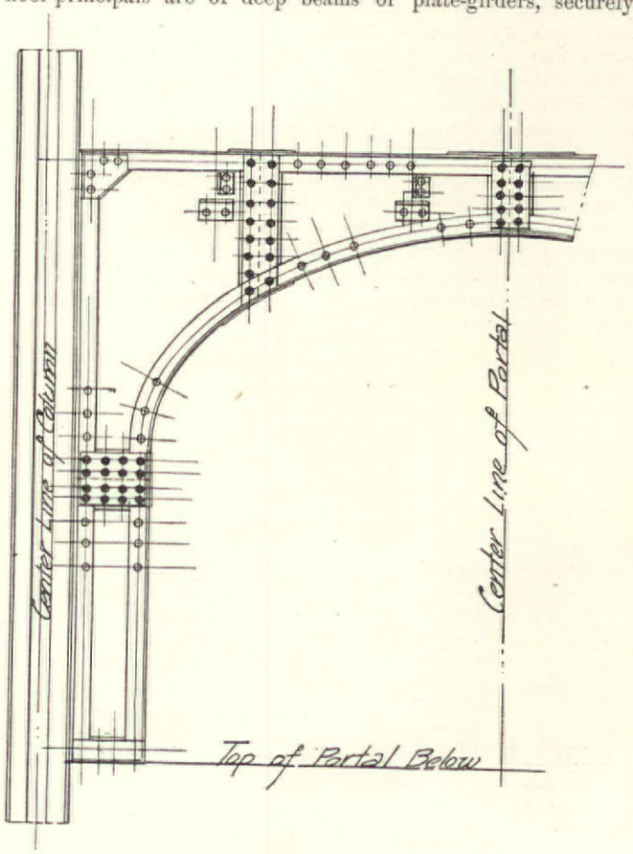

Fig. 59.

bolted or riveted to the columns. For buildings whose height is limited to two and one-half times their least base, it is probable that such connections offer the necessary resistance to lateral movement. Such connections may be employed in buildings as high as three times the length of their least base

when the exterior walls are substantially built, and when the building is braced by several brick partitions.

Second. — The most usual form of lateral bracing for buildings of moderate height is the gusset-plate or corner-brace.

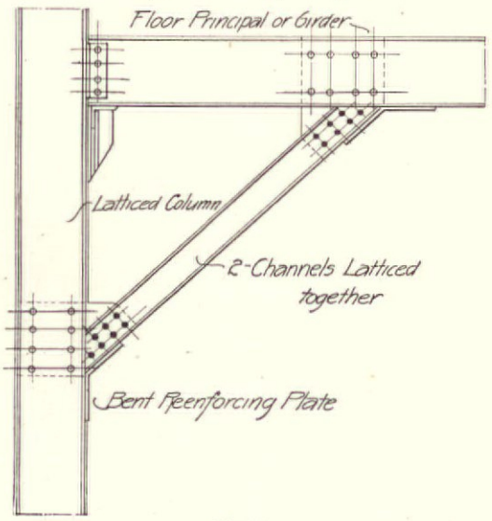

Fig. 60.

This consists of bracing the floor-principals to the column at its junction with this member by means of a triangular plate, usually reënforced with angles, extending at an angle of 45 degrees with the flange of the beam or girder, and the vertical axis of the column. A typical detail for such a connection is shown in Figure 57.

Third. — A system of lateral bracing has been evolved from the gusset-plate, which consists of a steel arch formed between the structural-steel columns, as designated in Figure 59. This detail of construction is known as portal-bracing, and is used in the lower stories or other certain sections of very high buildings. It furnishes great rigidity, but the cost is considerable, and it is open to the objection that it can only be used where the portal or archway is a feature of the architectural decoration.

Fourth. — A system of knee-bracing that is sometimes used is shown in Figure 60. It is efficient, but produces great bending-stresses upon the columns, a stress which is always an objection upon members subjected to compression, and of as much importance as the columns in a tall building.

Fifth. — Sway-bracing, which connects the cap of one column with the foot of the other by means of tension-rods crossed

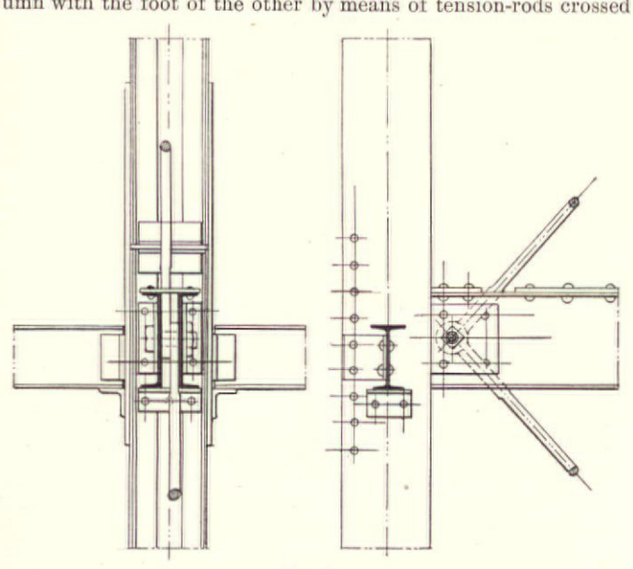

Fig. 61.

diagonally between the panels formed by the columns and the floor-principals, is, undoubtedly, most economical in material and construction. It makes of each set of columns a cantilever truss, its support being the foundation of the building, and its load the pressure of the wind against the area depending directly or indirectly for lateral support upon these columns. The objection to this system of bracing exists in the fact that the diagonals or tension-rods are an inconvenience in placing of doors or other openings; but usually this system of bracing is arranged so that the tension-rods or supports are contained within a partition. This type of bracing is shown in Figure 61.

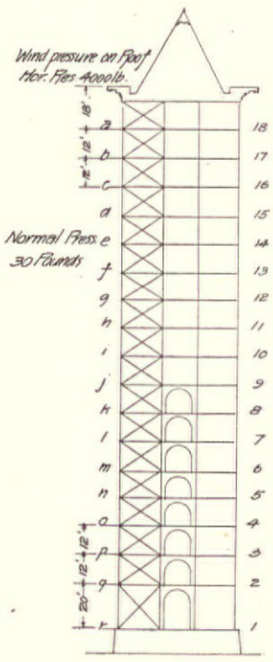

Fig. 62.

It is not necessary in tall-building construction to place a lateral bracing in bay, but it is usual to provide a system of bracing at several points throughout the length of the building. In a narrow building having a length of 100 feet or so, and a considerable height, it is usual to provide lateral bracing between two tiers of columns near the centre of the building. In a building of great length and of extreme narrowness, several systems of bracing would be required, which would be placed about one-fourth of the distance from the end of the building each way. In the location of the bracing much depends upon the situation of the building, and upon the plan, or interior arrangement — that is, the position of the partitions, or hallways.

In determining the stresses in the bracing for high buildings it is usual to assume a lateral wind-pressure of from 30 to 40 pounds per square foot of vertical surface. Since it has been determined that the maximum wind-pressure of 40 pounds upon a vertical surface is seldom realized, and is hardly probable, even if attained, to extend over a large surface, a pressure of 30 pounds per square foot is usually adopted. The stresses in the wind-bracing are maximum when the direction of the wind is normal to the external wall — that is, in a plane parallel with the bracing. In the consideration of the stresses in a braced frame of this character, any rigidity from the floor-construction or partitions that might be given to the building must be disregarded, for they are indeterminate. The floor systems can, however, be depended upon to transmit the direct horizontal shear due to the wind. Since even a pressure of 30 pounds per square foot is seldom attained, and also because, while the lateral rigidity imparted by partitions and floors must be disregarded, it still exists, and a low factor-of-safety is used in the design of the wind-bracing. The factor-of-safety usually employed is 3.

The method of determining the stresses in the several forms of wind-bracing differs somewhat, and though the solutions assume theoretical conditions, any errors are upon the side of safety. The determination of the stresses in the several methods of bracing may be taken up successively as follows: —

Before the stresses in any system of wind-bracing can be computed, it is necessary to determine the horizontal shear at each story due to the wind-pressure, acting normal to the exposed surface of the side of the building.

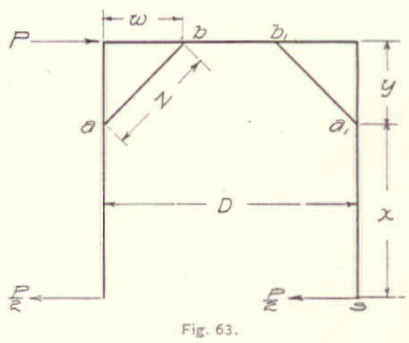

Fig. 63.

This shear is practically the same as would exist from a uniform load on a cantilever girder and is the accumulation of the loads at each story or tier of beams. For instance, in Figure 62 let the skeleton-diagram represent a cross-section through an eighteen-story building. The horizontal shear at the top floor is that due to the wind-pressure on the surface above *a* and including any horizontal pressure upon the parapet-wall or the sloping roof, but the shear horizontally at *b* is not that alone on the surface included between *a* and *b*, but includes as well the shear accruing from above the point *a*. Likewise, the horizontal

shear at c is equal to the pressure on the area from b to c, including the shears at a and b respectively, while the shear at the point d is equal to the pressure upon the area $c\,d$ plus the sum of the shears at c, b and a.

Assume that the length of the exposed surface on the side of the eighteen-story building shown in the figure is 20 feet and that the distance between floors is 12 feet, excepting the bottom story, which is 20 feet high, and the top story, which is 18 feet to the top of the parapet-wall, also that the horizontal wind-pressure per square foot of vertical surface is 30 pounds and that the pressure upon the sloping roof which must be taken care of by the bracing is 4,000 pounds. The horizontal shear at the several stories determined by the notation just described will then be as follows: —

Shear at point a = 18 × 20 × 30 + 4,000 = 14,800 pounds.
Shear at point b = 12 × 20 × 30 + 14,800 = 22,000 pounds.
Shear at point c = 12 × 20 × 30 + 22,000 = 29,200 pounds.
Shear at point d = 12 × 20 × 30 + 29,200 = 36,400 pounds.
Shear at point e = 12 × 20 × 30 + 36,400 = 43,600 pounds.
Shear at point f = 12 × 20 × 30 + 43,600 = 50,800 pounds.
Shear at point g = 12 × 20 × 30 + 50,800 = 58,020 pounds.
Shear at point h = 12 × 20 × 30 + 58,020 = 65,400 pounds.
Shear at point i = 12 × 20 × 30 + 65,400 = 72,600 pounds.
Shear at point j = 12 × 20 × 30 + 72,600 = 79,800 pounds.
Shear at point k = 12 × 20 × 30 + 79,800 = 87,000 pounds.
Shear at point l = 12 × 20 × 30 + 87,000 = 94,200 pounds.
Shear at point m = 12 × 20 × 30 + 94,200 = 101,400 pounds.
Shear at point n = 12 × 20 × 30 + 101,400 = 108,600 pounds.
Shear at point o = 12 × 20 × 30 + 108,600 = 115,800 pounds.
Shear at point p = 12 × 20 × 30 + 115,800 = 123,000 pounds.
Shear at point q = 12 × 20 × 30 + 123,000 = 130,200 pounds.
Shear at point r = 20 × 20 × 30 + 130,200 = 142,200 pounds.

When such a calculation has been made and the resulting horizontal shear has been obtained as above, and when the type of bracing has been decided upon, the calculation for the size of the several members entering into the design of this element in the structure may be found from the following formulas for the different cases.

Case I, the Gusset or Knee-brace. — A skeleton diagram of this system of bracing is designated in Figure 63 and the accumulated wind-pressure at the story under consideration is represented by p. This force p is assumed to be transmitted equally to the foot of the uprights or columns, so that at these points there will be a reaction equal to $\frac{p}{2}$ acting in opposition to p. The force p acting at the top of the frame tends to distort the panel to the leeward, and the result of this tendency is to create tension in the member $a\,b$ and compression in the member $a_1\,b_1$, and these forces while of different kinds are assumed as equal, and as there is under ordinary conditions as much likelihood of the wind blowing from one side of the structure as the other, whether gussets or knee-braces are used they must be proportioned to resist tension and compression. Under tension the member $a\,b$ tends to pull downward upon the floor-beam or girder at b, and under compression $a_1\,b_1$ tends to push the beam or girder upward at the point b_1. These forces require opposing reactions at these points, b and b_1, which must be furnished by the stiffness of the beam against flexure so that the wind-pressure acting on the frame causes bending in the floor beams or principals. Similar forces are exerted by the knees or angle-braces at a and a_1, so that the columns are subjected to bending as well as the floor-principals. Besides these several forces and their attending stresses the horizontal wind-pressure p tends to revolve the entire structure about the point s and, in consequence of the overturning tendency the left-hand, or windward, column is subjected to an uplifting tendency which must be resisted by tensile stress, while the right-hand, or leeward, column is subjected to a pressure corresponding in amount to the tension in the windward column and which creates additional compression in this column other than that due directly to the statical load from the live and dead floor loads.

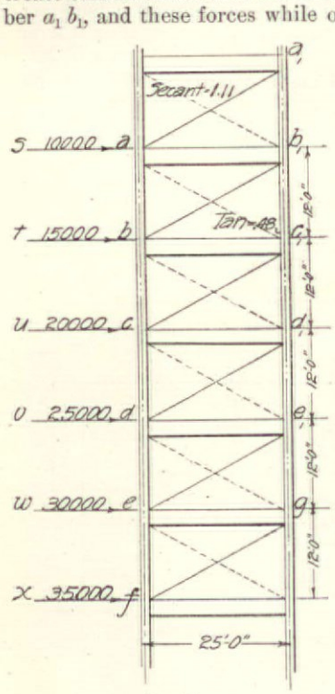

Fig. 64.

The amount of these several forces or stresses created in the different members may be determined by the following formulas in which the notation used in Figure 63 has been adopted in the expressions: —

Knee-braces. — Tension or compression $= P\left(\frac{1}{2} + \frac{x}{4\,y}\right)\frac{z}{w}$.

Columns. — Tension or compression $= P\left(y + \frac{x}{2}\right)\frac{1}{D}$.

Columns. — Bending-moment $= P\frac{x}{4}$.

Girders. — Tension or compression $= P\left(1 + \frac{x}{4\,y}\right)$.

Girders. — Bending-moment $= P\left(\frac{1}{2} - \frac{w}{D}\right)\left(y + \frac{x}{2}\right)$.

These formulas being exceedingly simple in their application need no examples for their demonstration. After the required stresses in the several members are obtained they may be proportioned by the rules and formulas for columns, beams or tension-members. The dimensions of the girders necessary to sustain the floor-loads must be increased sufficiently to take care of the bending-moment due to the wind, and in proportioning the columns the unit compression for the combined dead, live and wind loads must not exceed the unit compression allowed by the following formulas: —

For high buildings $s = 20{,}000 - 75\frac{l}{r}$.

For shed including mill buildings $s = 18{,}000 - 75\frac{l}{r}$.

In both of these formulas r equals the least radius-of-gyration and l the length of the column in inches.

By inspection of the bending-moment in the column at a and a_1, it would seem that the bending-moment would equal $\frac{p\,a}{2}$, but it must be remembered that the columns are rigidly fixed at the top and bottom so that the bending-moment at a and a_1 is about one-half this amount, or $\frac{p\,a}{4}$.

Case II, Sway or Diagonal Wind-bracing. — The skeleton of this system of bracing is shown in Figure 64, and by inspection it is clearly evident that where the diagonals are designed only to resist tension only one set is in action at the same time; the set not in action when the wind is to the left is shown by dotted lines.

The calculation for this system of bracing is quite simple and, as previously stated, involves the principles by which the stresses in a trussed cantilever are obtained.

The accumulation of the loads at the several stories are first found as previously described. Then referring to Figure 64, which shows a cross-section through a portion of a sway-braced building, the loads are as designated at $s\,t\,u\,v\,w$ and x, and these loads are the amount of the compressive stress transmitted by the floor-system and for the resistance of which additional section must be added to the principal beams or girders connecting the columns, unless it is assumed that the floor construction will provide sufficient resistance.

The stresses on the sway-rods bear the same ratios to the horizontal stresses or the stresses in the horizontal members as their length is to the length of the horizontal members. So that if the width of the building or the distance between centres of columns in a plane parallel with the bracing is considered as the radius, then the diagonal will equal the secant of the angle made by the diagonal with the horizontal members.

In the instance designated in Figure 64, the length of the diagonal is theoretically equal to $\sqrt{12^2 + 25^2}$, or 27.73, and the ratio between this length and the width of the building or the distance between centres of columns is equal to $\frac{27.73}{25}$, or 1.11.

The stresses in the diagonal members $a\,a_1$, $b\,b_1$, $c\,c_1$, etc., referring to the figure, will then be as follows: —

Stress in diagonal aa_1 = 10,000 × 1.11 = 11,100 pounds.
Stress in diagonal bb_1 = 15,000 × 1.11 = 16,650 pounds.
Stress in diagonal cc_1 = 20,000 × 1.11 = 22,200 pounds.
Stress in diagonal dd_1 = 25,000 × 1.11 = 27,750 pounds.
Stress in diagonal ee_1 = 30,000 × 1.11 = 33,300 pounds.

With the wind on one side of the structure as designated in the figure, and where the construction is similar to a cantilever-trussed girder with its support at the foundations, the columns at the windward side are in tension, while the columns at the leeward side are in compression. These stresses in the columns must be provided for in their design, and their increment bears the same ratio in each tier to the amount of the horizontal stress as the height of the columns from brace-connection to brace-connection bears to the width of the building or the distances from centre to centre of columns.

The length of the column with respect to the width of the building is equal to the tangent of the angle made by the diagonal with the horizontal, and the value of the tangent in this instance equals $\frac{1}{2}\frac{2}{3}$, or .48, so that the stresses in the columns, whether compressive or tensile, are obtained by the following calculations: —

Stress in ab = 10,000 × .48 + Increment = 4,800 pounds.
Stress in bc = 15,000 × .48 + 7,200 = 12,000 pounds.
Stress in cd = 20,000 × .48 + 9,600 = 21,600 pounds.
Stress in de = 25,000 × .48 + 12,000 = 33,600 pounds.
Stress in ef = 30,000 × .48 + 14,400 = 48,000 pounds.

In the design of the details for sway-bracing or diagonal-bracing the pin-connections at the ends of the diagonals should be carefully proportioned to resist both bending and shearing. Turn-buckles should be provided on all sway-rods and preferably they should be placed about 3 feet above the floor so that they may be conveniently tightened during erection. Where it is necessary to omit a diagonal in order to provide a door or window opening, the remaining rod in the panel should be proportioned for compression as well as tension.

Case III, Portal-bracing. — The principles of determining the stress in this system of bracing are much the same as those employed in the calculations of Case I for a gusset-plate or knee-brace, as it is readily observed that the portal-bracing is merely a form of the knee or gusset-plate bracing.

The horizontal reactions at the foot of the column in each tier are equal to $\frac{p}{2}$ when p equals the horizontal at the floor-level above. This reaction produces a bending-moment throughout the portal which may readily be determined by the principles of moments and it only remains to provide sufficient section throughout the portal to resist the resulting bending-moments. Besides these bending-moments, as in the case of knee-bracing, there is tension in the windward column and compression in the leeward one which is amply provided for in the large amount of excess metal necessary to employ in this type of bracing.

M. M. Sloan.

FRAME-BUILDING situated on the ocean-beach at Diamond Head, near Honolulu. Finish throughout the interior is hard woods, including mahogany, curly birch, bird's-eye maple, native koa wood, curly redwood and oak, etc. The dimensions of large drawing-room, or salon, on first floor are 50′ x 60′. A feature of the house is the continuous *lanais*, or verandas, on each story, overlooking the ocean. The plumbing, electrical equipment and decoration of this building are of the finest character, expert workmen having been brought to Honolulu from New York to execute these branches.

THE STATUS OF THE LOWELL MILL-OPERATIVE.

Boston, Mass., June 23, 1902.

To the Editors of the American Architect: —

Dear Sirs, — In your review of the conditions of the cotton-factories of Lowell you have stated the conditions under a misapprehension. You remark that the cotton-manufacturers thought it necessary in order to reduce the cost of production to lower wages to a point which would attract only the most destitute and ignorant operatives. The facts are that when cotton-manufacturing had become well established in Lowell, it was a step in advance for the daughters of New England farmers to leave the isolated, arduous life of the farm and to enter the factory, where they worked 13 hours a day in a low-studded, ill-ventilated, badly-lighted and badly-heated building. The machinery, being far from automatic, required the constant attention of a very intelligent person. In 1840 the average earnings of all the hands — men, women and children — in one of the best of the mills of the Lowell class averaged $175 a year. The average product per hand was less than 10,000 yards a year of 36-inch heavy sheeting. In what purports to be the same mill, of which nothing but a part of the foundation is the same, a high-studded, well-lighted, well-ventilated and moderately-heated building, the foreign operatives of to-day, who could not have worked the machinery of 1840, are now employed 10 hours a day with Saturday afternoon free, earning double the wages per hour, very nearly double the wages per day, as compared with the farmers' daughters of 1840, the average product per hand being nearly 40,000 yards a year. The cost has been diminished, the wages have been augmented, the price has been lessened, the profit required per yard to yield six per cent upon the capital has been reduced to about one-fifth of what it was in 1840. The farmers' daughters of New England and others of similar type and capacity have passed out of the factory into much less arduous and more attractive work at very much higher wages.

Progress in all these directions has been continuous, decade by decade, throughout the sixty years, subject to occasional fluctuations in times of commercial depression. That is the law of competition under which the working-people of the country, in the sense in which that term is commonly used, secure to their own use and enjoyment an increasing share or proportion of a constantly increasing product, this law only being interrupted in its course by the interference of trades-unions in their effort to keep the standard of earnings at the standard of the least capable among the workmen and women, attempting to prevent the capable from reaping the reward of their own superior ability. Yours very truly, Edward Atkinson.

NOTES AND CLIPPINGS

Decrease in Number of New York Stables. — A census taken by the Department of Health of the number of horses and stables in the city shows that there has been a decrease of 8,660 in the horse population from December, 1896, when it was 73,746, to June, 1902, when it is 65,086. The number of stables in December, 1896, was 4,649, and in June, 1902, 3,326, a falling off of 1,323. — *N. Y. Evening Post.*

Music and "Frozen Music." — George R. McKenzie, a sewing-machine manufacturer, built two Presbyterian churches in Jersey City and gave them to the congregations on the agreement that no musical instruments should ever be heard within their walls. The prohibition was fatal to both churches. The congregations dwindled down and down, and the last of them has just been closed because of non-support. Both buildings will be sold and the money used in aid of other Presbyterian churches. — *Exchange.*

Ventilating London's Tunnels. — As a result of the recommendations of Sir Benjamin Baker, practical steps have now been taken to ensure the efficient ventilation of the twopenny tube-tunnels in London. A powerful fan has been placed at the base of the left shaft at Bond Street Station, which will remove the vitiated atmosphere from the permanent ways, fresh air taking its place at the various halting-places under ordinary pressure. The fan, which is 48 inches in diameter, and electrically driven, displaces 30,000 cubic feet of air a minute, and is thus capable of entirely exhausting the whole of the tunnels in a fraction over 3 minutes. — *N. Y. Tribune.*

ANCIENT ITALIAN MONUMENTS. — In the course of a recent visit paid by the King of Italy to the Roman Forum, Signor Boni, director of the excavations, pointed out to His Majesty the incongruity of leaving the site of the Roman Senate covered up by a comparatively modern Spanish convent. The view of Signor Boni has commended itself to a number of Italian public men, who have drawn up a motion calling on the Minister of Public Instruction to provide means for the demolition of the convent and the excavation of the site. The motion will be discussed by the Chamber during the examination of the estimates for public instruction. At least a hundred signatures had been affixed to the motion, and it is practically certain that Signor Nasi, Minister of Public Instruction, will make no objection to its adoption. Thus, within the next year, it may be hoped that the remains of the old Roman Senate will be brought to light after having been buried for so many centuries. This is not the only proof of the new interest which the Italian Government and, in particular, the Fine Arts and Antiquities Department of the Ministry of Public Instruction are taking in the preservation of ancient Italian monuments. Efforts are being made, and, as a rule, successfully, to prevent a recurrence of the blind demolition of venerable remains that went on in Italy 20 years ago. The Director-General of Fine Arts and Antiquities constantly sends to the various regional offices of his department the strictest and most precise instructions as to the treatment of archæological remains, and in the majority of cases the local officials show great zeal in executing the orders received. But in Italy the greatest obstacle to any efficacious control and preservation of ancient monuments is the perverse belief that the desire to preserve them is due exclusively to archæological mania. By degrees the advance of education is removing this prejudice and is ensuring a more general respect for the claims of history and civilization, and it is satisfactory to note that nearly every battle undertaken for the preservation of some historical fragment terminates nowadays in the defeat of the vandals. One illustration of this is the action of the Ministry of Public Instruction on behalf of the old walls of Bologna. It was proposed to destroy the ancient structure almost entirely, as a result of the growth of the city. The Ministry has succeeded in obtaining the suspension of the demolition, which had begun at three points, and has made sure that any partial demolition that may be rendered necessary by the growth of traffic and the need for more direct communications shall in no way harm the monumental value of the old walls. At Genoa the Ministry of Public Instruction has averted the danger that threatened the beautiful cloister of Sant' Andrea. The Genoese municipality wished to buy the cloister from the Prisons Administration, to which it belongs, in order to sell the area to private speculators. The Ministry of the Interior, at the request of the Ministry of Public Instruction, has, by its intervention, prevented such a misfortune. Similar intervention at Novara has saved the Sforza Castle from being sold to the municipality and damaged. At Verona a regular campaign has been necessary to prevent the distortion of the famous Piazza delle Erbe, where local vandals wished to erect a large modern theatre. The Piazza Civica at Pistoja is still threatened by the promoters of a monument to Garibaldi, who wish it to be placed alongside the statue to Cardinal Forteguerri. Here, again, the Department of Antiquities is gradually persuading the local enthusiasts for Garibaldi not to spoil the symmetry of the piazza with a modern monument, but to place their statue elsewhere. It seems strange that in a country like Italy, which draws such a considerable part of its prosperity from foreign tourists and visitors, who are attracted to the country by its ancient monuments, there should be so little respect for the records of the past. The only explanation is that ignorant familiarity breeds contempt. The hope of students must be that with the gradual disappearance of ignorance familiarity may yet breed reverence. — *Correspondence of the London Post.*

THE CUENCA CATHEDRAL ACCIDENT. — The Madrid correspondent of the *Times* writes under date April 15th: — "The catastrophe which befell the Cathedral of Cuenca the day before yesterday will not be without some good result if it stirs the authorities to take a little more interest in the reparation of ancient buildings which lie outside the general track of visitors. Cuenca, some 60 miles east of Aranjuez, though an inconsiderable town itself, possesses a fine Gothic cathedral of the sixteenth century, but little known on account of its distance from the most frequented centres of Spain. It would appear, from a question asked in the Senate yesterday by the Count de San Luis, that the dangerous condition of the cathedral tower was recognized so long ago as 1888, when a grant of 100,000 pesetas was solicited from the Government for its repair. The money was not forthcoming, and no adequate measures have since been taken to ensure the safety of the tower. It has now fallen, causing the death of some six or seven people, chiefly children, and threatening the further collapse of a great portion of the cathedral itself. As a matter of fact, the burden of repairs should properly fall upon the municipality, but it is a duty which can hardly be efficiently performed by the *ayuntamientos* of small and impoverished towns, and it would be well if, in their case, the Government could come to their aid."

ELECTRICITY IN BULDING-WRECKING. — Cutting-up tanks electrically is being done in the Auditorium Building, Chicago, by Mr. J. E. Haschke. According to the *Western Electrician*, four elevator-tanks, 12 feet high and 24 feet in circumference, had to be removed, and the noise of the work, if done in the usual manner, would be highly objectionable to the music-teachers and theatre-goers in the building. The electrical cutting is done at the rate of about 1 foot in 2 minutes. The current is supplied at 110 volts by the electric-plant in the building, and is reduced to 30 volts by apparatus of which the design is a secret. One terminal of the circuit is connected to the tank to be cut, and the other to an anthracite carbon 1 inch in diameter, the metal being heated by the arc between it and the carbon. — *Building News.*

GERMAN OLD-AGE PENSIONS. — Emperor William is considering the extension of the old-age pension legislation. Conversing with a recent American visitor about the conditions of labor in the United States, His Majesty said he was determind to make employers contribute to the support of their work-people when the latter were old and invalided. They should not be thrown aside like old shoes after having given all their best years to their employers' interests. Germany already has a fairly comprehensive old-age scheme in operation, but the doles guaranteed are not sufficient to maintain the receivers without private aid. What the Emperor apparently intends is to secure enough to keep the aged people beyond want. Of course they will have to contribute a portion of their wages, throughout their lives, which the State will invest, supplemented by a regular quota from their employers. — *N. Y. Tribune.*

PREHISTORIC VILLAGE IN WISCONSIN. — From discoveries recently made in ploughing up the soil for what is known as the Mitchell Park Addition to Milwaukee, Wis., the place was evidently the site of a large village centuries ago. Grooved stone axes, hammer-stones, arrow and spear heads, and great quantities of flint-chips have been found, and indicate that stone weapons were manufactured on the spot in numbers. Several members of the archæological section of the Wisconsin Natural History Society have visited the place and made a superficial examination, and they have come to the conclusion that there must have been a prehistoric village there, covering 150 or 200 acres. Further investigations will be made, and it is believed that something more definite regarding the inhabitants of the village will be learned. — *N. Y. Evening Post.*

AMERICAN ART-PURCHASES. — The art-critic of the *Vossische Zeitung* complains that American millionaires have sent up the prices of paintings to such a point that European collectors are now unable to compete with them. The fact that pictures go to the United States, says the critic, does not mean their loss to the world, as European artists often assert, and many of the older American collectors often showed genuine appreciation and understanding of art. Quincy Shaw recognized the merit of the Fontainebleau school when its pictures could not be given away in Paris. Mr. Shaw made a larger collection of the paintings of that school than all the French collections put together. The critic of the *Vossische Zeitung* also mentions Henry G. Marquand and Allan Marquand, of New York, and Mrs. Gardner, of Boston, as discriminating picture-collectors. He deplores, however, the invasion of the art-field of the younger generation of American millionaires, whom he declares to be without real artistic appreciation, saying they make it possible for picture-dealers to increase the price of pictures tenfold and thus shut out European buyers.

OLD WOOD-CARVINGS. — Although in the Priory at Christ Church, Hants, at Westminster Abbey, Salisbury Cathedral, and in a few other of our ancient minsters, there may be seen to-day miserere seats and (as at Salisbury) other small portions of stalls dating from the middle of the thirteenth century, the oak in each of which is as sound now as it was in the days when the respective monarchs of the forest bowed their sturdy heads to the woodman's axe, the palm, as regards seniority, is claimed, and justly so, by Exeter Cathedral. Therein, in the choir, may be seen fifty miserere seats, every one different, cleverly carved and enriched by figure and by foliage, the oak in each and every one of them perfectly hard and solid, and altogether innocent of the least indication of rot or decay, carved under the direction of Bishop Bruere (tenth Bishop of Exeter), who ruled over this diocese from the year 1224 to that of 1244. Taken as a whole, they are not only the most perfect examples of early thirteenth-century work in this country, but also in any cathedral or church in the world. Bruere (or William Briwere, as he is sometimes called in ancient manuscripts) was for nearly 5 years away in the Holy Land. This accounts, no doubt, for the altogether Eastern character of some of the figure-carvings upon these superb misereres. One of them represents an elephant, and is of exceptional interest, in that it is the earliest carved representation of that quadruped in existence in England. It is curious, too, in that its carver, apparently never having seen such an animal, has represented it with the hind legs of a dog, although, as we all know now, an elephant's hind legs possess hocks precisely the same as do the fore ones, and hence its ability to kneel down like a Christian. But, after all, we are but a new people; and what with us appears to be ancient history is very modern indeed, when we come to compare ourselves with some other countries — Egypt, for instance. The most ancient carved-wood figure — it is of sycamore — known to exist may be seen in the Museum of Gizeh, at Cairo. It dates from B. C. 3900, so is very nearly 6,000 years old, and still the wood is sound and good. This precious old statuette was found at Sakkarah, and is supposed to represent one of the overseers of the workmen engaged in building the pyramids which abound in that immediate neighborhood, and, by comparatively recent discoveries, have been proved to be the oldest of all the pyramids of Egypt. The statue is known as the "Sheikh-el-Beled," or "Sheikh of the Village," a name given it by the Arabs who found it, because its features represented very closely those of the man who was then their own sheikh. In this we get a wonderful instance of how human nature, through the roll of thousands of years, keeps on repeating itself. The statue is distinctly a portrait, showing a jolly, well-fed, closely shaven man of fifty summers or thereabout, altogether nude, save for a cloth bound by a leather girdle about his lusty loins, and reaching down to his knees. He stands erect, and in the right hand grasps a staff, but I do not think the latter is part of the original. The exact height of the statuette is 3 feet 8½ inches. A careful cast in plaster-of-Paris of this wonderful old carving was made early in 1894, and may now be seen in one of the Egyptian Galleries of the British Museum. This, then, is the oldest known existing example of the wood-carver's craft. — *The London Woodworker.*

NOTES AND CLIPPINGS. 8

THE provision made by Congress for new public buildings covers four which will probably, under the Tarsney Act, be opened to limited competition among selected architects. These four are situated at Washington, Providence, San Francisco and Los Angeles. There is to be a new Post-office in the city of New York, but nothing has been done except to authorize the selection of a site, and proposals for this purpose have already been invited.

THE Treasury Department has made some important rulings explanatory of the clause in the Dingley tariff permitting the importation, free of duty, of works of art by American artists residing temporarily abroad. There has always been a question what constituted temporary residence, and the Treasury now decides that the duration of temporary residence shall not be limited by any fixed period, provided the artist has not renounced, or intended to renounce, his American citizenship, but declares, in the manner prescribed by the Treasury regulations, his intention, at some later period, to return to this country. The children born abroad of citizens of the United States, who have not renounced their American citizenship, are also citizens of the United States, and entitled to the privileges accorded by the Dingley Act. On the contrary, a wife takes the citizenship of her husband, and an American woman artist who marries a foreigner thereby expatriates herself, and cannot claim the privileges of the Dingley tariff. In order to establish the identity of works of art imported under this clause of the Dingley Act, they must be accompanied by the declaration of the artist, or of actual witnesses of their production, or by other evidence satisfactory to the Collector at the port of importation; but it is not necessary that they should have been purchased directly from the artist, transfer of ownership not affecting the privileges conferred by the Act.

THE Massachusetts Institute of Technology has received a gift of five thousand dollars, with the promise of five thousand a year more for two years, for the purpose of conducting investigations in sanitary science, including the questions of the purification of water, and the disposal and utilization of sewage, garbage and other wastes. The work will be carried on under the direction of Professor W. T. Sedgwick, the present head of the Department of Biology of the Institute.

IT is interesting to observe how rapidly the judiciary is taking in this country the place which it has occupied for so many centuries in England, as the guardian of liberty, in England against the encroachments of royal prerogative, and in this country against attempts at organized oppression. A few days ago the Supreme Court of Wisconsin, which has already distinguished itself for its clear judgment in such matters, handed down a decision, declaring a State law prohibiting an employer from discharging a man because he belongs to a labor union to be unconstitutional and void. As the Court well says, if the employer's liberty to say whom he will hire, and under what conditions he will employ him, can be curtailed by legislation, the liberty of the laborer can also be curtailed, and he may be compelled to work against his will for persons, or under conditions, unsatisfactory to him. To put the matter in another way, if it is lawful for politicians or labor unions, through legislation, or in any other manner, to compel employers to submit to dictation in the employment of labor, then it would be equally lawful for the employers, if they should get a chance, to compel laborers, against their will, to submit to such terms as they might choose to impose; that is, to enslave them. Many of the States, through the political influence of the labor unions, have statutes by which the members of the latter, a small minority, it should always be remembered, of the actual working population, are given undue and tyrannical advantages over the rest of their fellow-citizens. Through these unjust laws the community in general suffers continual distress and loss, and such a decision as that of the Wisconsin Court, which, by its clear and convincing logic, is likely to influence judicial action all over the country, constitutes an important step in the development of American liberty.

ONE of the principal reasons why judicial decisions upon the right of labor unions to control other people's business are needed is the growing damage inflicted upon employers and employed alike by the personal squabbles of unscrupulous labor leaders, and the means which they use in pursuance of their private ends. Not long ago, there was a very serious and prolonged strike in the mills of the American Woollen Company. The Company operates many factories, in different States, and, while grievances may have existed in one or two mills, the operatives in the others were contented. This state of affairs, while it makes a settlement of differences, by arbitration or otherwise, very easy, does not suit the agitators, who know well that a quarrel without any tangible ground is generally the most difficult to settle, as well as the most vindictive; and they endeavor to enlist as many people as possible, by "sympathy" or otherwise, in a dispute in which they have no personal concern. In the case of the American Woollen Company, they were hindered in their efforts to bring about a general strike in all the mills of the Company by the circumstances that most of the operatives had no reason for striking, and no wish to do so. To meet this objection, it occurred to some of them to send to each mill, to be read before the members of the union in that mill, a letter from the Secretary of the Rhode Island Union, making statements and appeals calculated to arouse the sympathies of the members. This device was quite successful, and it was not until after more strikes had been declared, and misery brought into hundreds of households, that some one asked the Secretary of the Rhode Island Union about the letter, and discovered that he never wrote or signed any such document; that he entertained no such sentiments or ideas as those expressed in it, and that the whole affair was an impudent forgery from beginning to end.

OF course the American Woollen Company suffers to a considerable extent by strikes brought on by such means, but their loss is insignificant in comparison with that of the poor weavers thus heartlessly deceived into sacrificing their living. To those connected with building affairs, who have many occasions for seeing how essential to the comfort of myriads of humble, but happy, homes is continuous employment for the working members, and how quickly the interruption of employment shows itself in the pale faces, the patched clothes and worn-out shoes of innocent children, who do their best to bear bravely their undeserved misfortune, there is something exasperating in the knowledge that these miseries are often brought about for the sole purpose of gaining political influence, or attracting bribes, for the men whose authority ought to be used in befriending the poor, and that, worse than this, the men who so infamously betray those whose interests

Entered at the Post-Office at Boston as second-class matter

they pretend to protect do, in point of fact, very often secure the offices or the bribes which they seek by such means. In default of means for bringing politicians to a sense of their duty in such matters, the courts form the best resource; and if there is no way in which men who are deceived into abandoning their employment through forged letters can obtain pecuniary indemnity, it is certainly possible for them to proceed under the criminal law, and they may be sure that judges and juries will help them to make such transactions hazardous.

AS an illustration of the burden which class-legislation in favor of the members of labor unions imposes on the whole community, the present strike in the anthracite coal region may well be studied. Wherever in this country a kitchen stove, or a furnace, or steam-boiler, depends for fuel on anthracite coal a heavy tax has for some weeks past been exacted, and will continue to be collected for some weeks more, to pay a part of the cost of an unnecessary contest, brought on by an attempt at the sort of coercion of the employers which the Wisconsin Court has declared to be unlawful, and maintained against the will of the great majority of the miners themselves, by the same sort of unlawful coercion of the men who wish to go back to work. Besides the sum which the community is obliged to contribute in the shape of an increase in the cost of coal, toward this unlawful demonstration, it pays, in addition, a heavy indirect tax, through the impoverishment of the miners, who are said to have lost in wages, since the strike began, not far from fifty million dollars, and are so much the less able to buy for themselves and their families the comforts and necessaries, the manufacture of which would have given employment to a vast number of their fellow-citizens.

CONSIDERING that only about fifteen per cent of skilled mechanics, according to the statistics, really belong to labor unions, the friends of liberty and equality will not be sorry to hear that Corporation Consul Rives, in New York, has given his opinion that city authorities cannot legally provide in contracts that only members of unions shall be employed on the work contemplated by the contract, for the reason that such a stipulation establishes an illegal and unconstitutional discrimination between different classes of citizens, at the same time that, by excluding from city contracts all but certain privileged persons, it prevents competition among contractors.

MR. HENRY F. HORNBOSTEL, of New York, well known in the profession as an accomplished and well-trained architect, has been appointed consulting architect to the New York Department of Bridges. The Commissioner of Bridges, Mr. Lindenthal, has long favored the development of the artistic side of bridge-designing, and Mr. Hornbostel is well qualified to aid in such matters.

THE National Academy of Design, in New York, has taken the radical step of abolishing all tuition-fees for instruction in its classes in drawing and painting. Considering the number of schools of the kind, of a very high grade, already existing in New York, which are dependent upon a small tuition-fee for support, as, for example, those of the Art Students' League, the action of the Academy looks a little like unfair competition; but the standard of admission to the Academy has always been high, and if, as the managers of the schools hope, the abolition of fees should enable them to raise it still higher, the effect upon artistic education ought to be favorable. At the School of Fine-Arts, in Paris, tuition, as every one knows, is free, yet the School stands, probably, higher than any other in the world; and if the National Academy can take graduates from the League schools, the Cooper Institute, the Pratt Institute, Columbia University, and the other excellent schools of fine art, and develop them, in a few years, into rivals of the great French artists, it will be a most important factor in the development of American art. To rival the Paris School, however, the Academy should have something like the resources of the French institution. It must not only have an additional endowment to pay the expenses hitherto met from tuition-fees, but should be able to offer the brilliant prizes which the French School holds out to faithful workers in all departments. It should have a Prize of Rome, or something equivalent to it, carrying, as the Prize of Rome does, Government favor and assured employment for life, and should be able to offer also special prizes in various departments, so that those whose talents lead them in particular directions may have the hope of winning, in the work most congenial to them, a lifelong reputation, as well as considerable sums of money.

THE HONORABLE FRANCIS G. NEWLANDS, Member of Congress from Nevada, who is well known for his intelligent study of many matters of public interest, delivered a speech a few weeks ago before the House of Representatives on the Reclamation of the Public Lands, which is well worthy of study. Mr. Newlands is not at all given to bombastic declamation, and his clear and dispassionate statements carry conviction with them. In fact, so reasonable are his views that we think he would find the opposition of the Eastern farmers to the pending irrigation bill, which, at best, is, we imagine, less serious than he seems to suppose, materially lessened by the extensive dissemination of the report of his speech. As every one knows, the plan now under consideration in Congress contemplates the adoption, on the part of the Government, of comprehensive measures for storing, at the most advantageous places, the flood waters of the rivers rising in the Rocky Mountains and elsewhere, so that they can be released for use for irrigation when needed in the dry weather of summer. It is obvious that the Government of the United States, which alone has jurisdiction over the course of a river flowing, like most of the Western streams, through several States, and can condemn and take lands in any State, is the only agency by which great works of the kind in this country can be efficiently and economically carried out, at the same time that, as owner of six hundred million acres of arid, or semi-arid, land, it has the largest interest in the results of the undertaking. The plan in contemplation, as described by Mr. Newlands, is for the Government to build dams and construct main canals, in such manner as to collect all the water possible, leaving the settlers to build branch canals at their own expense, in such a way as may best suit their agricultural operations. The bill provides that the work, which must of necessity go on slowly, shall be paid for out of the proceeds of the sale of arid public lands, so that no money will be taken from the Treasury for it; and it is provided that the cost of the reservoirs and canals shall be apportioned over the territory served by them, and added to the price of the land; so that, as sales of the reclaimed land are made, the cost of reclamation will be repaid. Nothing could be more sensible and rational than such a scheme, and there seems to be no reason why it should not be carried out successfully. It is true that the speculative schemes for irrigation works which have been carried out in various parts of the Southwest have almost always ended in a loss to the stockholders, but, even if honestly and economically managed, they have been conducted at a disadvantage, through the limitation of their powers of taking land, and, as a matter of fact, it is notorious that they have, in many cases, been utilized for swindling in the grossest manner the Eastern capitalists who furnished the money for them.

THE great Hygeia Hotel, at Fortress Monroe, where many of our readers have probably found health and happiness, is to be removed, to clear the ground for military purposes. As every one knows, the hotel stands on the Government reservation, as do also many other establishments of the same kind, public and private. For many years they have occupied the ground on sufferance, but the War Department has decided that it is necessary for military purposes to have the whole area cleared, and has given orders for the removal of all buildings within a reasonable time.

M. AGERON, a French architect of distinction, died a few weeks ago under circumstances which have a melancholy interest for the profession. Although still a young man, he had acquired a high reputation for professional skill, and had been repeatedly called in as expert in important cases. A group of school-buildings, in process of erection in the city in which he lived, had shown signs of imperfect construction, and he was called upon by the municipal authorities to undertake the supervision of the work. He found certain materials defective, and, as in duty bound, reported his discovery to the municipal officials. For this reason, apparently, no other being given, the contractor waylaid him at the railway-station, where he knew that he would find him, and shot him dead. What has been done to the murderer we are not informed, but criminals of this kind do not often escape, in France, the punishment that they deserve.

ITALIAN BELL-TOWERS.

"CAMPANILE," in Italian, has the same signification as "bell-tower," in English, "*clocher*," in French, and "*Glockenthurm*," in German, and the oldest bell-towers of Italy hardly date back beyond the fifth century. This is proved by the mosaic on the triumphal arch of Santa Maria Maggiore at Rome, a work of the time of Sixtus III (430–40), where towers rear themselves alongside a baptistery and basilica; and even on the celebrated wooden doors of S. Sabina at Rome there exists something which seems to be a tower (these doors are of the fifth century, of the time, as it appears, of Celestin I, or about 422–32). But we are not at all certain that these towers had bells in them, so one ought to call them simply towers, or *torri*. It is certain, all the same, that bells were in use in Italy in the eighth century, during the pontificate of Stephen VII (752), who in giving bells to the Vatican Basilica must have introduced their use into the Eternal City in the middle of the eighth century. This statement of Amalario's, Bishop of Treviri, a contemporary of Charlemagne, cannot be accepted without some reservation. However that may be, at present, the most ancient bell in Italy, that of the Museo Falconi at Viterbo, has been acknowledged to belong to the eighth or ninth century, and it is, in truth, an article of venerable antiquity. It is very simple, this bell of the Museo Falconi, as it has no artistic pretence whatever unless in the general mass, which has a certain elegance of line and the peculiarity that there is a triangular hole and an engraved design which De Rossi, prince of Christian archæologists, believes to be the roof of a three-nave basilica. Add a cross to the curved extremities characteristic of the seventh and eighth centuries, and you will have an image of the general appearance of the Falconi bell as it was exhibited for the last time at the feast of the Eucharist, at Orvieto, in 1896.

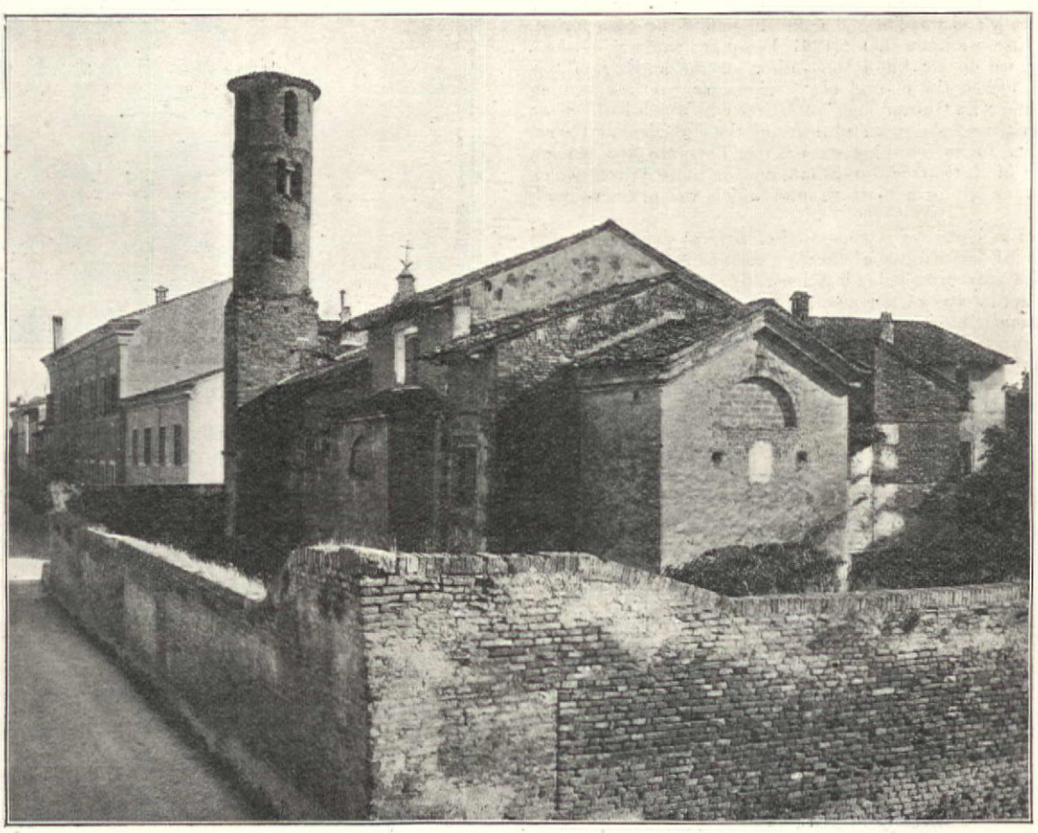
Well, though I ought only to speak here of bell-towers, allow me to say that De Rossi compares the Falconi bell to a certain representation in the codex at the Library of Bologna, whose assignment to the ninth century has not yet been seriously disputed.

Now let us come to the monuments.

In Italy there are very few churches with bell-towers on the flanks of the façade or rising near the apses. In Sicily there are the cathedrals at Cefalu and at Monreale. In Apulia — a monumental corner of the Peninsula very little known — are the cathedrals at Altamura, Molfetta and Bari; in Æmilia, the cathedral at Borgo S. Donino; in Lombardy, the churches of S. Ambrogio and S. Sepolcro at Milan, as well as S. Abbondio at Como; in Piedmont there is S. Andrea at Vercelli; in Liguria, the Cathedral of Genoa, one of whose towers is still unfinished. In other countries, on the contrary, limiting myself to old Europe, church façades with two towers are numberless, and are found in France, Germany, England, among those in the Romanesque and Gothic styles.

In the same way, in Italy, there are very few churches with more than two towers, as we see in the case of the cathedral at Palermo and at Borgo S. Donino, and fewer still are those with a single tower in the middle of the façade, as in the case of the churches of S. Maria del Tiglio, at Gravedona (Lake of Como) and S. Matteo in Campo d'Orto, at Perugia. So, with us, almost all churches have single bell-towers, and some that are isolated, but erected quite near to the church building. In this last category may be mentioned the cathedrals at Pisa and Florence, the Church of S. Zeno at Verona and St. Mark's at Venice.

The oldest bell-towers on the Peninsula are surely the Byzantine ones at Ravenna, round like that of S. Apollinare in Classe, which is the most beautiful of the Byzantine towers of that city, which might be called an Italo-Byzantine Pompeii. The tower of S. Apollinare in Classe dates to the same epoch as that of S. Apollinare Nuovo at Ravenna, generally given as the eighth century, but in my opinion it is still older. A beautiful round tower of the same kind is that of SS. Giovanni and Paolo, also at Ravenna, lately brought out into sight by means of reasonable restorations. In short, the Byzantine towers of Ravenna by reason of their form or by their construction are remarkable specimens of the most ancient bell-towers in Italy. This emphasizes the fact that with us the most ancient bell-towers were often round. A tower of this same form that is very little known, even to Italians, is to be found at Caorle, in Venetia, and it is to be regretted that I could not obtain for you any photograph of it. But I can give a reproduction of the bell-tower of S. Satiro at Milan, justly considered the oldest of the square bell-towers, the square form having remained characteristic of almost all of the Italian bell-towers. This is a structure of the ninth century, of serious character and simple motive, one of those monuments which are always preserved with the greatest care. Milan and Lombardy possess several of the finest Italian bell-towers, among others the tower called "dei Monaci" of the basilica of S. Ambrogio, which, from the historical point-of-view, has many rights to be mentioned here. But for artistic towers we must leave the centuries earlier than the year 1000, and turn to the eleventh, twelfth and thirteenth centuries. It must be remarked, however, that some amongst these towers which date back beyond the year 1000 one would like to call older yet. This, also, might be said of several of the mediæval churches in Italy. For example, I will mention S. Maria in Cosmedin at Rome. This tower, of a perfect elegance and exquisite air, is indeed attributed to the eighth century, but, for me, it belongs to the twelfth. By the side of this



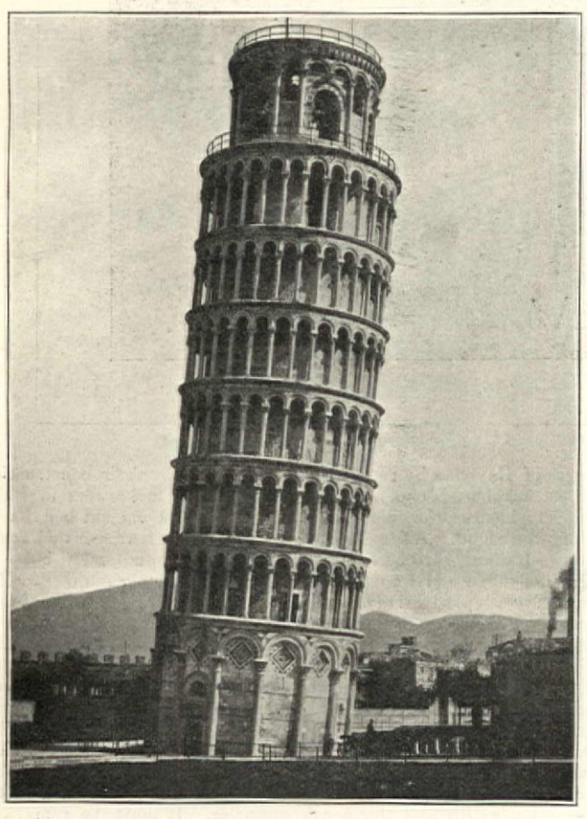
SS. Giovanni e Paolo, Ravenna, Italy.

celebrated tower we will find in Rome that of S. Maria in Trastevere, which dates from the time of Innocent II (1130–43), and also that of S. Maria Maggiore, the origin of which does not go back farther than the twelfth century. It is evident that this tower has been restored, and history tells us that these restorations took place in the times of Gregory XI (1370–78) and Paul V (1605–21). Bell-towers are typical of the Eternal City, and one must bear this in mind. Rome possesses other remarkable towers — those of SS. Giovanni e Paolo, a work of the twelfth century, and S. Croce in Gerusalemme, built at the end of the same century, a century which inspired the architect of the tower of S. Spirito in Sassia who, like the modern eclectic architect, introduced forms belonging to the full Renaissance. This brings it about that this architect dressed up a mediæval organism in details belonging to the fifteenth century.

The centuries following the year 1000 have brought us to the more celebrated towers of Lombardy, Æmilia and Tuscany. Here we are before the "Torrazzo" at Cremona, admirable in its elegance and in its fineness of ornament, a *chef d'œuvre* of great renown, which surpasses, and by much, that of the city in which the tower rears itself, where it is esteemed like a jewel in its casket. This is entirely a brick structure, a material greatly used in Lombardy and Æmilia. The history which relates to the Torrazzo most often is based on ancient traditions which have nothing of serious value belonging to them. The real truth is this: the tower of Cremona cannot date back to the eighth century, and the old writers deceived themselves, since historic reasons, as well as those of art and construction, demonstrate that the Torrazzo was begun in the twelfth or thirteenth century and was finished about the end of the same period, as it appears, since we know that in 1267 the square part was finished. Unfortunately, we do not know the author, or the authors, of this Torrazzo, considered the marvel of Cremona, as are the leaning tower of Pisa and "La Ghirlandina" of Modena, of which I will speak after having criticised the graceful tower of the cathedral at Crema which resembles, in its crowning stories, the Torrazzo at Cremona and the tower of S. Gottardo at Milan, one of those jewels which the Middle Ages left as a heritage and which we preserve with pride.

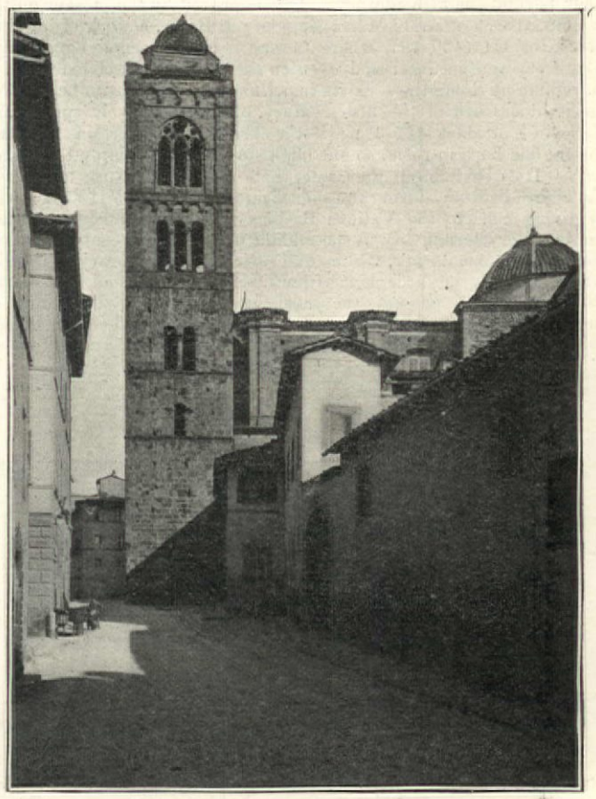
The tower of S. Gottardo is composed of several stories, crowned by a conical roof carried on a circular colonnade, and the brick and the discreet polychromy give it a decorative aspect which is very striking. Its author was a Cremonese, "*Magister Franciscus de Pecoraris de Cremona fecit hoc opus,*" and its date the first half of the fourteenth century, which speaks to us of an age extremely happy for Italian fabrication.

In accordance with Italian Chauvinism "La Ghirlandina," that is to say, the tower of the Cathedral of Modena, is the peer of the Torrazzo, but the tower at Modena is very far from possessing the



The Campanile, Pisa.

beauty of the Torrazzo. The Modenese, however, do not esteem their tower any less than the Cremonese esteem the tower of their cathedral, for in certain Italian towns there exists a true communal pride in their own monuments, and very often the most remarkable monuments are used as symbols of the city. The lower or square portion of the Ghirlandina was built, it appears, at the same time with the cathedral, and finished in 1159. Above this portion of the structure rise the octagonal and pyramidal portions which were built



Campanile of the Cathedral, Pescia.

between 1261 and 1319, according to the plans of Arrigo da Campione. Lately, the restorations carried out on the tower at Modena have cost the city a large sum.

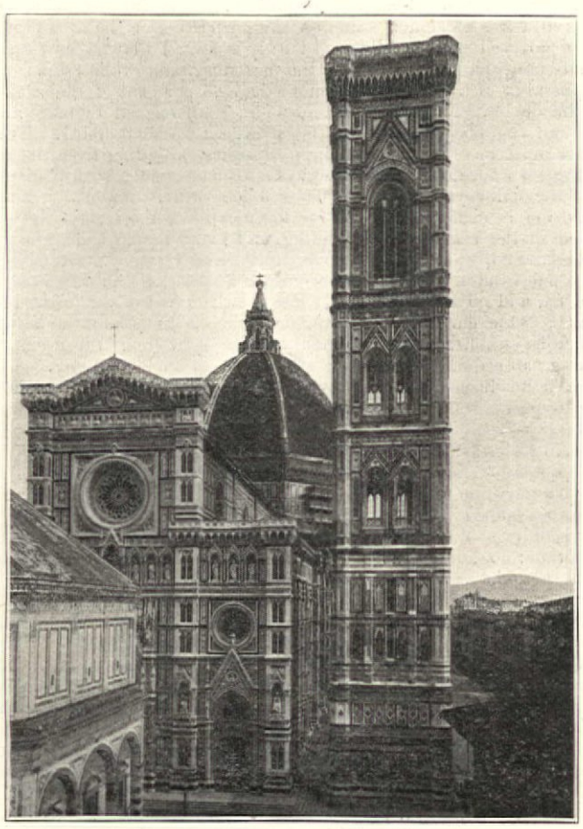
Near Modena, at Bologna, in Æmilia, the towers "degli Asinelli" and the "Garisendi" enjoy the highest reputation. The first belongs to 1109, the second to 1110. These are two leaning towers, but civil and not ecclesiastic, as are the others which are the subjects of this article. They can, nevertheless, be brought to mind here, before speaking of the celebrated leaning tower of Pisa, the tower of the most famous and superb cathedral in the Romanesque style in all Tuscany.

Everybody knows the "Campanile of Pisa," better known for its inclination, perhaps, than because of its open loggia treatment, too much repeated. It was finished in 1174 by the architect Bonanno, and, most often, like the towers of Bologna, it is admitted that its inclination is accidental. Upon this subject we can remark that when the inclination was discovered in the lower vaults the architect endeavored to apply a remedy, and history tells us that during a certain length of time the work was stopped and it was then that the architect was changed. Bonanno was replaced by Guglielmo of Innsbrück, who did not, however, continue the work to the end, as the tower was finished by Tommaso da Pisa, to whom reverts the honor of having placed upon the summit of the tower a bell-chamber.

Its departure from the vertical is very noticeable, being 2.40 metres, and the question whether the inclination was accidental or intentional has been frequently discussed. The last author who has resolutely willed to hold himself apart from the generally accepted opinion is your Professor Goodyear, who, in his remarkable studies on the refinements of Italian architecture of the Middle Ages — studies only just current in Italy — has not hesitated to profess his belief that the displacement of the tower of Pisa is one of those effects of art, one of those *bizarreries* in which the architecture of the Middle Ages abounds. Professor Goodyear points out that even on the façade of the Cathedral of Pisa there exists a certain displacement from the vertical and then a return to the vertical, and this North American writer, who has a love for such subtilties, as Pennethorne and Penrose had for those of Greek architecture, brings together such a quantity of facts drawn from our architecture of the Middle Ages that one must listen to him with the most respectful deference; this I shall do here, and I shall do so elsewhere, in the fourth edition of my "*Manuale d'Architettura Italiana,*" which I hope will be brought out in the first months of the coming year.

Quite near Pisa are Lucca, Pescià and Pistoja, whose respective cathedrals have important towers. The tower at Pescià, unfinished and dating from the middle of the fourteenth century, is very little known. Its robust and simple construction, which does not deprive

it of grace, urges me to exhibit it here, but I am far from according it the importance which the pretty tower at Pistoja deserves. This tower, which rises square in plan to the very top, recalls the open loggia treatment of the campanile at Pisa, although at Pistoja the use of these loggias, common to the Romanesque architecture of



The Campanile, Florence.

Tuscany, is more modest. The decoration of the tower, in white and dark-green marble, gives it an air of lightness while preserving to it its imprint of majesty. The author of the tower of Pistoja is not known as are the authors of the campanile at Pisa, but his style indicates the epoch, the end of the thirteenth century or the beginning of the one following.

The railroad leads from Pistoja to Florence in forty minutes. Florence possesses the most celebrated tower in all Italy, a glorious monument which at once calls up Giotto's name. But is this evocation a legitimate one? This is what we are going to find out after having noted at Florence the tower of S. Maria Novella and that of the Badia (1330), two towers which, while very models, are far from having the beauty and the richness of Giotto's tower.

The tradition of ages gives to Giotto the honor of being the architect of the campanile which rises at the side of the Cathedral of Florence and, although this tradition may be devoid of all authenticity, in Italy, at least, one cannot separate the campanile at Florence from the name of the reviver of Italian painting.

It is very sure that Giotto laid the foundations of the tower in 1334, but, dying in 1336, he was replaced by Andrea da Pisa, who ought to be called Da Pontedera; but this master, whose place in the history of art is that of a sculptor and in no way that of an architect, was dismissed, because he desired to introduce certain changes in the tower. It was then that the Florentines entrusted the direction of the work to Francesco Talenti, the real architect of the campanile of Florence; that is to say, the architect of the upper stories, the most beautiful and glorious portions of the construction.

Amongst the Italian artists of the Middle Ages in the architectural field, Talenti was in very truth one of the most distinguished and the most forgotten, and that one of the writers upon art who shall produce a study of this Florentine artist will exhibit to the public and students of art a new architect of real genius where there was believed to be one merely of the second rank. Talenti accepted the direction of the work on the Florentine tower at the time when that work was hardly begun, and having finished it his name should take the place of that occupied by Giotto. It is not probable that Talenti followed the drawing of the immortal painter, which might be identified with that which is found on a parchment in the Cathedral of Siena, a design which is strikingly grotesque in taste.

I regret that a general study such as this is does not allow me to stop longer on these particular matters. I beg the reader, therefore, to believe that my affirmation is supported by facts.

I turn now to Southern Italy, and in Apulia we find the tower of Trani, a monument of particular importance because it is signed by an artist who has some points of resemblance with Talenti, as being long forgotten. This is "*Nicolaus sacerdos et protomagister*," who built a great portion of the tower, finished in the second half of the fourteenth century. In Apulia, also, admirers of towers will find at Bitonto the campanile of S. Leo, a work of the thirteenth century, simple, logical, robust and elegant. I do not refer to the towers of the Cathedral at Bitonto, renewed in the fifteenth century, the origin of which dates back to the first quarter of the thirteenth century.

I turn now to Sicily, whose mediæval architecture has a peculiarly Arabo-Byzantine-Norman-Sicilian, eclectic air; in a word, pervaded by an eclecticism which passes all prevision, and produces in the history of architecture a page full of attractiveness and charm. Of this you will gain an idea from the illustration of the towers of Monte S. Giuliano and of Girgenti in the first place.

Everywhere here the pointed arch appears in full twelfth-century work, and we see in this pretty fragment of the tower of the Cathedral of Girgenti ogee arches, arches, that is, formed by two curves having different directions, and we can remark in this same fragment the zigzag decoration in the archivolt of the topmost window. Here it is necessary to remark that it is not a matter of an isolated motive, but of a motive which is very widely scattered in Sicilian architecture, the Norman origin of which cannot be put too much in evidence. This kind of ornament was preserved in Sicily up to the end of the fourteenth century, and I believe that the fragment we have before us belongs precisely to that epoch.

The most important Sicilian bell-tower, however, is that of the church called the Martorana, at Palermo. The construction of the tower is intimately connected with that of the church, and the church, which, as well as the Palermitan bridge over the Oreto, was built in 1143 by Giorgio d'Antiochia, a celebrated dignitary of the Norman court, was richly endowed in 1146, and before taking on the name of Martorana was called S. Maria dell' Ammiraglio, a name which has been preserved to this day. In time, to the old church was annexed a monastery, founded by Aloise Martorana, which brought about the change of name, and in the sixteenth and seventeenth centuries changed greatly its physiognomy.

Amongst the portions preserved is the tower, which presents a picturesque *ensemble* of a kind quite new for the Italians of the Continent. It is the upper stories which most generally are appreciated, and travellers ought to examine the details and, above all, the pretty capitals.

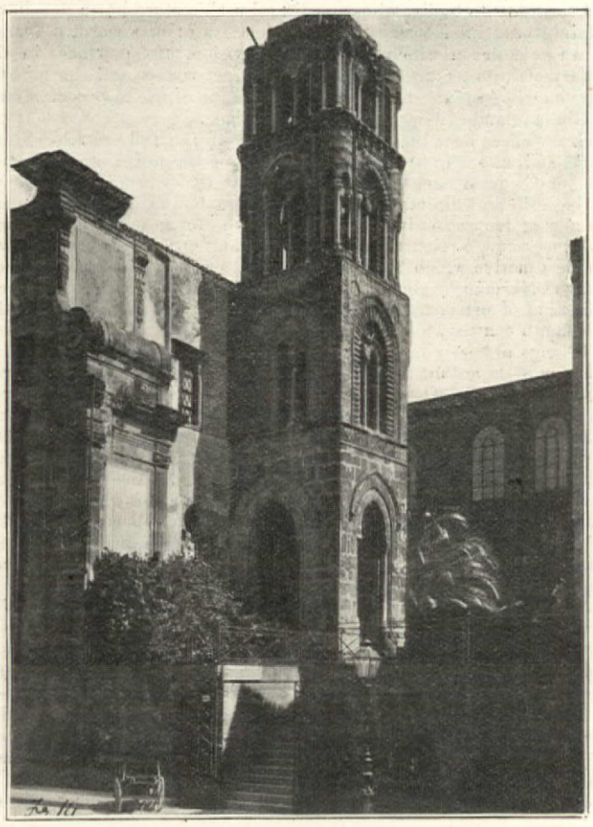
At Palermo, when visiting the Cathedral, one is impressed by the towers which surround it; — at the beginning of this paper, I pointed out that the Cathedral of Palermo was one of those rare Italian monuments decorated with several towers.

At length, taking our way northward, after the Gothic tower of

Lower Part of Tower of the Cathedral, Girgenti.

the Cathedral of Albenga, near Genoa, one of the most beautiful in Liguria, after the tower of S. Agnese in Genoa, dating from 1260, and, on the north side of the Peninsula, after the tower of the Abbey of Pomposa, a monument which even in Italy has remained too much unknown, I take my leave of the subject by drawing attention to the

Tower of S. Mark at Venice. A leaning tower, this one, too, but not sensibly, as in the case of the towers of Bologna and Pisa, but which possesses the strange peculiarity of having no stairs. Instead of staircases, there are inclined planes, on which you can ascend to the top of the Venetian tower afoot, on horseback or on bicycle, if you will. It is enough to cast one's eyes over the monument to perceive that it belongs to two epochs profoundly different, and that the

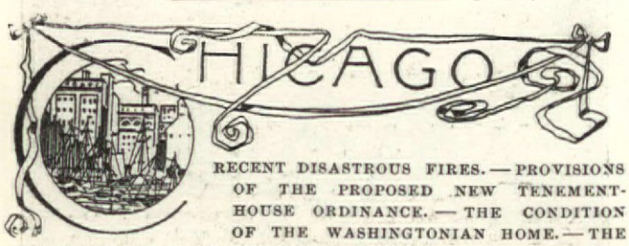


The Campanile: Church of the Martorana, Palermo.

tower of S. Mark's, begun before 948, was begun anew in that year, according to some, or in 1068, according to others, or in 1147, according to still others, and in the course of the centuries underwent several periods of construction before its completion. The records speak of works dating back to 1310, to 1489, to 1511; in fact, in 1489, a thunderbolt struck the tower, and Giorgio Spavento designed the restorations, and in 1511 a thunderstorm again damaged the structure. It was then that the Tower of S. Mark received the upper stories, according to the plans of Bartolomeo Bon, of Bergamo.

To point out one more interesting detail: it was pretended that the foundations of the tower were as deep as the tower is high, and likewise that these foundations were star-shaped in plan. Although these assertions are found in books and are widely disseminated, I draw attention to the fact that during the excavations carried on in 1865 it was learned that the foundations of the Tower of S. Mark are not over 5 metres deep, and there is nothing remarkable in such a depth as this.

ALFREDO MELANI.



RECENT DISASTROUS FIRES. — PROVISIONS OF THE PROPOSED NEW TENEMENT-HOUSE ORDINANCE. — THE CONDITION OF THE WASHINGTONIAN HOME. — THE INCREASED COST OF BUILDING. — THE MARSHALL FIELD AND THE "TRIBUNE" BUILDINGS.

WITHIN the last six months, the number of disastrous fires in Chicago, with attendant loss of life, has been most appalling. Tenement and flat buildings have gone down like houses of card, giving their occupants scanty chance of escape; many of them, with their would-be rescuers the firemen, have been either injured or killed. It grew to seem the usual, rather than the unexpected, to be greeted with such horrors when the morning paper made its appearance.

About a week ago a very disastrous fire occurred on the South Side, in what had been once an old hotel, but which was known as St. Luke's Sanatorium, a resort for those addicted to the excessive use of drugs and liquors. Here the violent patients, who were locked in their rooms, were simply roasted alive, the building going so quickly that no help could be given the poor unfortunates. All these serious accidents have led, first, to the reconsideration of the building-ordinance, and, secondly, to an investigation of existing hospitals and similar institutions, with a view to formulating building-laws for the better protection of their inmates.

The new tenement-building ordinance, which is now being considered, takes a decided stand on the proportion of the area of a lot to be covered by a building. In it, it is stated that no new apartment-house shall occupy, above the first story, more than 80 per cent of the area of a corner lot or more than 65 per cent of the area of an inside lot. No new tenement-house shall exceed by more than one-half the platted width of the street on which it abuts. Every house must have at least one flight of stairs extending from the roof to the entrance-floor. All stairways must be provided with banisters, and the hallways must be at least 3 feet wide. Naturally, ample provision is made in the bill for fire-escapes. Yards must be provided in the rear of each building, and every inside court must be unobstructed, save by the fire-escape. Every room must have at least one window opening directly upon a street, an alley, a yard, or a court, and no room shall offer less than 400 feet of air to the individual. One curious item in the ordinance is the standard of light which is established. Every hall must be light enough to permit of reading an ordinary newspaper at noon on an unclouded day.

"All inside courts must have 10 feet of space between windows and opposite walls, while all outside courts must have 5 feet of space.

"All stairways must be enclosed within brick walls for the sake of fire-protection.

"All partition-walls between apartments must be of brick or some fireproof material.

"Buildings of four or five stories must be of slow-burning construction; buildings more than five stories must be of fireproof construction.

"A notice must be posted in the public hall of each apartment-building by the Building Department, stating that the building has been constructed in accordance with the laws of the city."

These are some of the chief points in the ordinance known as the Mavor Ordinance, from the name of Alderman Mavor, who has fathered it, and, in consultation with Fire-Chief Musham, has worked it into shape. Such philanthropists and sociologists as Jane Addams and Prof. Graham Taylor are deeply interested in the matter, and are anxious to see the ordinance passed by the Council. They feel that the area limitation is one of the most important features. The opposition to this comes from the speculative builder, who builds neither for the present good of the tenants nor the future good of the city. Should the ordinance be passed by the Council, it is further hoped that the laws will be held in force. Several items in the ordinance, like the provision for brick walls between apartments, are not new, but they have been practically a dead letter for some time.

Since the disastrous St. Luke's Sanatorium fire an investigation is being set on foot by the Board of Health and Building Department, which will include inspection of all hospital buildings throughout the city. So far only the Washingtonian Home, a hospital for inebriates on the West Side, has been investigated, with a result that was not entirely satisfactory. It was found that patients that were violent were confined on the third floor in windowless rooms, the walls of which are lined with wood. In this part of the building, where the doors are of heavy wire and securely locked, there are no fire-escapes. In the main part of the building there are no elevators, and the fire-escapes were found to be unsatisfactory. Certainly the practice of locking helpless patients in high stories, when there is no adequate system of fire escape, is to be condemned, and should be controlled by law.

Building-interests are moderately active here, though nothing like a building-boom is in sight, nor will there be one so long as the price of building is kept up to where it is. On any house built anywhere at a cost of from $4,000 to $25,000, the advance of the cost of building at present over that of 1899 is over 37 per cent.

The increase is due not only to the stand taken by the trades in their different unions, but also to the tremendous increase in the price of material, the result of trusts and combinations in manufactures and supplies. True, much more luxury and elegance is demanded in the average home of to-day than in the one built, say, five years ago even, but this is only a side issue in the subject of the increased cost of building. Certain it is that all classes interested in building transactions are overreaching themselves, for there is nothing more sure to put a stop to activity along these lines than the extortionately high price of materials, as it stands at present. Labor is higher than formerly and naturally helps materially to increase the cost of building, but, as said before, the largest increase comes with the higher price of materials. The same paper quoted above further gives a list of the actual increase of profits now expected and demanded, against that demanded in '99.

"Foundation and excavating contractors' annual profit sought now, 33 per cent; in 1899, 15 per cent.

"Plumbing-combine profit sought now, 150 per cent; in 1899, 50 per cent.

"Electrical manufacturing and supply combine, annual profit sought now, 135 per cent; in 1899, 45 per cent.

"Brick combine, annual profit sought now, 75 per cent; in 1899, 30 per cent.

"Glass combine, annual profit sought now, 100 per cent; in 1899, 50 per cent.

"Lathing, plastering, interior finish, annual profit sought now, 40 per cent; in 1899, 20 per cent.

"Heating-apparatus combine allied with plumbers, figures about the same.

"Hardware, annual profits sought now, 60 per cent; annual profits in 1899, 35 per cent.

"Mosaic and tiling work, annual profit sought now, 30 per cent; in 1899, 12 per cent.

"Labor's return is estimated to have increased from 3 to 10 per cent since 1899, making labor still the cheapest part of the expenses of house-building."

Two prominent buildings mentioned in these letters before as being in the process of construction are now practically completed and thrown open to the public. These are the Marshall Field retail building and the Chicago *Tribune* Building. If one were to hunt the world over for a building which was nearly devoid of all architectural pretensions, one which ignores every chance of a line of grace or refinement of touch or design, no better example could be found than this same Marshall Field Building. The material is granite, the lines hard and uncompromising for the first seven or eight stories, then some carving crops out in the last story or two, of a nature too weak to "carry" from the height at which it has to be viewed. The very grouping of the windows is staring and uncompromising. Two narrow divided windows stand either side of a broad plate-glass sheet, unbroken even by the usual middle sash-line. This combination, regularly set, continues through six or seven or eight stories, beginning just above the first two, one of which contains the usual show-windows of the retail dry-goods store. The entrance of the structure is a portico of Classic pretensions. Huge monolithic granite drums rest on flat, characterless bases, raised on solid granite blocks. The Doric caps would lead one to expect a fitting Doric base, and the lack of proper moulding comes as rather a shock: when so little is attempted one would naturally expect to have that little of a refined and satisfactory nature. The interior of the building is quite in keeping with the exterior; absolutely no attempt at decoration in any form or kind is visible. The building is light and airy, and at present as white as whitewash and plaster and plate-glass can make it from end to end. That is all, and in spite of the gay trappings of a great dry-goods emporium, the place is cheerless and bare.

The *Tribune* Building is quite the opposite in character to the Marshall Field one. Its material is buff Bedford-stone and brick. Bronze is the material used for the lower window-sashes and linings of vestibule, giving a warmer tone to the general color of the lower stories. One curious and successful feature is the changing of the usual large first-story windows in the office-department into small ones of ordinary size, raised 4 or 5 feet above the sidewalk. The effect is very good and doubtless has also a utilitarian purpose, as the higher windows must be more suitable for a place where large crowds at times assemble, as they do around a newspaper office. The grouping of the other windows is unaffected and dignified, and much more pleasing than in the building just mentioned. The ornamentation of the first story chiefly centres around the entrance, but is strong in design and good in execution. It, as well as that reserved for the upper stories is of Classic feeling, that placed in the higher parts being sufficiently strong to carry well, and means something from the sidewalk-level. The building at present is twelve stories high, but it is said that eventually four more stories will be added to it, which will in no ways add to the attractiveness of the façade, it is to be feared.

The entrance is an interesting feature of the building. Columns with monolithic shafts flank either side, while the chief interest in the ornamentation centres around the eagle and wreath, of classic proportions, above the door. Bronze electroliers, of very charming design, flank either side. The vestibule is lined with bronze plates, bearing bas-reliefs of the past homes of the *Tribune*, beginning as far back as 1847, with an old two-story wooden structure, where the newspaper's quarters were in the second story, above the drug-store, which was on the first floor.

The entrance-hall is not large, but is very attractive. Entirely lined with white marble of good quality, the inlaying of green and pearl mosaics in the ceiling makes a charming color-scheme. Marble stairs, with marble balustrades, lead up on either side to the second story, while the walls above the first-story level are relieved by columns, mouldings and arcades. This is naturally a great improvement on the usual square slabs of marble, with which entrance-halls are often lined, and gives a much more architectural effect. The slabs of marble used in the arcaded portions are especially beautiful, being large and unusually free of flaws. The bronzework, of which there is a great deal around the building in window-sashes, door-frames, office fixtures, electroliers and elevator-cages, cars and fittings, is charming, both as to design and execution. The Winslow Brothers' castings are as certain to be a delightful feature in a building as Tiffany glass or mosaics.

The entire building, both in general character and detail, is one of the most successful of the large office-buildings erected in Chicago for some time.

A rather unusual structure, and also a very striking one, is the Bush Temple of Music, on the North Side. Its material is a light buffish brick combined with white terra-cotta. It is in the early French Renaissance style. Its general lines are excellent, the whole effect being striking and picturesque, with its high pointed roof broken into two side gables, the central portion surmounted by a clock-tower. The details are disappointing, and the pleasing impression made by the general appearance of the building is not confirmed by them.

Our friend the local reporter on architecture, to whom reference has been made before, especially distinguished himself in his description of this building. He says the building "is designed after the Hôtel de Ville, Paris, and built of brick, tile and steel. Only three buildings in the city are of this particular style of Gothic architecture: the Newberry Library, the Chicago Historical Society, and the *Record-Herald* Building." How could he have picked out any three buildings more lacking in resemblance to it than these? The libraries are both Romanesque, the Newberry of an especially dignified and simple type, while the *Record-Herald* Building is in no special well-recognized style, but is a happy adaptation of past forms to nineteenth-century needs, which the late John Root knew so well how to handle.

INCOMBUSTIBLE LIFTING-SASH WINDOW-FRAMES.

TO THE EDITORS OF THE AMERICAN ARCHITECT: —

Dear Sirs, — After reading the admirable and sagacious papers lately published by Mr. A. J. Bloor, on those fairy-tale phrases, "fireproofing" and "fireproof buildings," I wrote the following: —

"Any one who has seen a fire begin in a building knows with what incredible rapidity the flames mount the vertical trim, or architraves of doors and windows. In 1875, in a banking building in Wall Street, New York, I substituted cast-iron trim. But this is clumsy and expensive. In 1895, for the Colt Memorial Building at Hartford, Conn., I found that by crimping folds in sheet-copper, I could imitate the pockets for the weights and sash of the lifting-sash window. Instead of wooden sash, the ordinary leaden sash of glass-stainers can be substituted, and metal chains for the combustible cords. I felt that whoever would widely introduce such incombustible windows would be entitled to the gold medal of the Royal Humane Society. The advantages of lifting-sash windows, for purposes of prompt ventilation, are well known. Any worker in sheet-copper who has a crimping-machine can readily construct such a window for exhibition purposes, and, on exhibiting it, would probably receive a profitable supply of orders for such windows.

"So much for windows; now for doors. The secret of absence of fires in Florence is mainly that the locks are on the outside of the doors, instead of being mortised into their thickness, as in America. Hence, the jambs of the doorways do not need any rebates for the doors to shut against, and no wood is needed. The rebates are on the doors themselves, and shut against edges of thin marble slabs, sawn out and stood up against the brickwork of the jambs of the doorways. The American habit of always demanding what one is used to prevents the appreciation and the use of these and other far-seeing contrivances, which make fires in Florence of rare occurrence, and, when they do occur, they do not spread, or cause much damage."

NOTES AND CLIPPINGS

The Ruins at Copan. — Among the ruined Central American cities of ancient culture, Palenque, Quirigua, the Usumatsintla towns, Tikal and Copan, the last-named attracts the greatest interest at present on account of the resumption of archæological explorations there. Its ruins are situated on the banks of Copan River, Southern Honduras. The site where the main temple stood is now a square platform with steep declivities on all sides. The temple is gone, leaving no trace behind except the western approach. When the Peabody Museum of Archæology, at Cambridge, sent its first expedition to the spot in 1891, the whole structure was overgrown with heavy timber. The elevation where the temple was is now known as Mound 26; at present it looks like a high pointed pyramid, the apex and sides of which have been considerably reduced by the disintegration constantly going on. The western side of this pyramid presents the greatest architectural feature that has yet come to light in Copan, namely, the "Hieroglyphic Stairway." The steps of this stairway were formed by large stone blocks carved on the front side with the well-known calculiform figures, some of which are intended for numerals, and others for names, generic terms, and the like. The first who directed attention to the stairway and the excellent design and workmanship of its component parts was Maudsley, and his genius also pointed out the former importance of the spot, of whose earlier shape heavy landslides had made recognition well-nigh impossible. From the latest measurements it appears that the whole width of the stairway, including the balustrades of 3½ feet, was 26 feet; that of the altar at the bottom, 12 feet. As regards height of slope, the portions of the stairway still *in situ* measure 25 feet, which is just one-fifth of the whole slope once covered by the stairway. The probability is that there were 80 carved steps from the base to the top of the stairway where the temple stood. The several human figures which decorated the centre of the stairway show the sculptural art to have been crude, though full of promise, and the whole structure must once have left on the spectator a weird and awful impression. Of the inscription which formerly decorated the stairway, but a few broken fragments remain. The story is told by George Byron Gordon, with admirable photographic illustrations, in No. 6 of Volume I, of the *Memoirs of the Peabody Museum.* — *N. Y. Evening Post.*

Clerkenwell's Historic Gateway. — St. John's Gate, Clerkenwell, London, was erected after the insurrection of Wat Tyler, at the end of the fourteenth century, for that gentleman's levies took the trouble of burning down the old gate, which had stood for two centuries before their time. It had been built when St. John's Priory was erected there by the Knights Hospitallers, after the crusade of the first Richard. The gate is built of brick and freestone; its walls are quite 3 feet thick, and its towers were formerly much higher than they now are. These towers are in four stories, and over the gateway itself will be noticed a room which is the most famous of all rooms over bars in this country. For in this upper room Cave set up his press in 1731, and from it issued the first number of the *Gentleman's Magazine*. Here came Richard Savage in search of work at the hand of Cave, and there he subsequently spent much time in writing; here labored for the magazine a greater than either Cave or Savage — one Samuel Johnson, whose fame was later to become immortal. Here the great David Garrick made his *début* in London. Into this room came a jovial Irishman named Oliver Goldsmith in search of Johnson, and here the two friends often passed many hours in converse. Here flourished later the Urban Club, a literary coterie of reputation in its day. But many years before these men of letters had given a special interest to the place there had been royal business transacted in this very chamber; it was here that Richard III came to tell the Council how cruelly and bitterly his foes lied about his treatment of Lady Anne Neville, his wife. Close by the gate lodged the Princess Mary, when her brother, Edward VI, was on the throne, and here he often visited her. Elizabeth had her court revels rehearsed in the gateway chamber before they were performed at her palaces, and the brave old gate bore no small part in the Sacheverell riots of other days. The room at the base of the west tower was in 1813 a house for the watch; it was then made into a dispensary for the hospital; then it became a coal-shed; and later it blossomed out into a bookshop. To-day it is the headquarters of that noble institution, the St. Ann's Ambulance Association. — *Windsor Magazine.*

Lumber and Timber Products. — In the Census report on the "Utilization of Wastes and By-products," Mr. H. T. Kittredge says: "Nearly all of the formerly waste products of lumber and timber are now turned to some utility, and some of the new products thus formed are of considerable value. Of this latter class may be mentioned sawdust, which was formerly considered an absolute waste material, and was allowed to float down the stream or was thrown into a heap where it could be most conveniently disposed of. French cabinetmakers have found a way of preparing this material which gives it a value far above that of solid timber by a process that has been in vogue for at least twenty-five or thirty years, combining the use of the hydraulic press and the application of intense heat. By this process the particles of sawdust are formed into a solid mass capable of being moulded into any shape and of receiving a brilliant polish, and possessing a durability and a beauty of appearance not found in ebony, rosewood, or mahogany. This product is known as '*bois durci*.' Artificial woodwork, therefore, seems to have a promising future. Alum, glue and sawdust, kneaded with boiling water into a dough, and pressed into moulds when dried, is hard and capable of taking on a fine polish. Ornaments of great beauty can be made from it very closely resembling carved woodwork. The production of acetic-acid, wood-naphtha, and tar from sawdust is one of the latest enterprises in Norway. A factory has been started at Fredrikstad capable of distilling 10,000 tons of sawdust in a year. It also manufactures charcoal briquettes, which are exported to the Netherlands. The acids are chiefly placed on the German market, while the tar is mostly consumed at home. The factory is said to be the first of its kind erected in that country. According to an English patent of 1897, sawdust may be so prepared as to be non-inflammable, and then applied to jacketing of boilers and other purposes."

Investigating the Lightning-conductor. — Time uses its broom effectively when it is given sufficient latitude. It has long been accepted as a truth that lightning-conductors are an efficient protection for high buildings, tall chimney-stacks, etc. This belief now appears to have been called in question. There are few people to whom the truth of this matter will be of greater importance than the textile manufacturers of the country. Their buildings, except weaving-sheds, are nearly all lofty, while to every separate establishment there is a tall chimney-stack. Nearly all are fitted with lightning-conductors, yet they are not infrequently damaged by the electric-fluid. These facts, being in apparent conflict with accepted views, have led to a number of scientific men forming themselves into a lightning-research committee, which has for the past eight or ten months been giving its attention to the subject. Until the Committee began its work it was generally assumed that a conductor protected a considerable area around it, or attracted the bolt if near, and conducted it harmlessly to the earth. The information which the Committee has so far collected does not bear this out, as the lightning has sometimes been found to strike and commit damage within a few feet of the conductor. The conclusion the Committee has drawn from present information is that a single conductor affords practically no protection, and may even be a source of danger. If the thorough protection of a building is possible, it is alleged, it can only be effected by a network of protectors spread over or around the building, and with many earth connections. The network would distribute the electricity, which would find its way to the earth through the various rods. Above all, the researches of the Committee have completely exploded the theory of the value of a single rod on a church-tower or lofty chimney. It is highly desirable that the truth should be ascertained and incontestably established. — *Manchester (Eng.) Textile Mercury.*

Whistler as a West Pointer. — "West Point in 1854" is the subject of an interesting article by Loomis L. Langdon, in the *Army and Navy Journal*. Speaking of James McNeil Whistler, the writer says: "There was a curious story told of the way he didn't pass his examination after remaining at the Academy three years. The subject given him in chemistry to discuss before the Academic Board was 'Silica,' which constitutes 8 per cent of the solid matter of our earth. Whistler, it is said, in perfect innocence of the subject, but with his characteristically charming manner, discribed silica as an 'elastic gas' or 'a saponifiable fat.' The young ladies in the audience smiled approval, but the stern Academic Board dispensed with Whistler's further valuable services at the Military Academy. He found employment for a time in the United States Coast Survey at Washington, but, finding that his compensation 'hardly paid for his gloves,' he went to London, and years afterward made a reputation as a painter."

Proposed Colossal Statue of Australia. — There is talk of erecting at the entrance to Sydney Harbor, as a monumental tribute to the triumph of federation, a colossal statue of "Australia Facing the Dawn," a sort of rival to "Liberty Enlightening the World," from the island in New York Bay. Funds, however, have not been forthcoming, and now it is reported that one of the principal advocates of the project has written to Lord Rosebery suggesting that a contribution from the £3,000,000 left by Cecil Rhodes to "promote the consolidation of the English-speaking people" might be legitimately allocated to this purpose. — *Boston Transcript.*

NOTES AND CLIPPINGS. 16

THE proposed consolidation of the Departments of Architecture and Music in Columbia University with the courses in history and practice of fine-art connected with them, into what may be called a rudimentary school of fine-arts, has given occasion for a discussion which cannot fail to be of value, whichever side those interested in it may take. For the present, the plans of the Trustees of the University contemplate nothing further than a more complete correlation of the courses which they already offer. Except in architecture and music, they do not profess to offer a complete training in any art, and their view, that while all men of education may derive benefit from some knowledge, practical, as well as theoretical, of the arts of painting and sculpture, those who are in preparation for the careers of architecture and music will find great advantage in a concentration, if we may use the expression, of the artistic atmosphere in which their years of study are passed, is abundantly justified by experience. Notwithstanding the conservatism of the plan described by the Trustees in their official announcement, it seems to be assumed by the public that the University will later undertake to turn out graduate painters and sculptors as well as architects and musicians; and the artistic community has taken for its theme of conversation this assumption rather than the actual scheme proposed.

AMONG the comments which have appeared in the newspapers on the subject, the greatest weight should perhaps be attached to a letter from Professor Russell Sturgis, addressed to the President of the University, and published in various newspapers. Although we cannot entirely agree with Professor Sturgis in some of his ideas of artistic education, most of his letter is of great importance and value; and while it does not seem to us to be quite relevant to the actual scheme proposed by Columbia University, it is, as an essay on the general subject, which is one of the most pressing now before the community, well worthy of extended circulation. As an accomplished and learned artist, and an experienced teacher, Professor Sturgis finds it necessary to call attention in the most emphatic manner to the necessity of technical training, above everything else, in the education of those who are to practise painting and sculpture. These, he reminds us, are manual arts. Undoubtedly, they are the greatest of the manual arts, but this does not alter the fact that skill of hand and eye is absolutely essential to both of them, and that without this manual skill no intellectual power, and no mental training, can ever produce good works of sculpture or painting. As, in his judgment, the manual skill requisite for the practice of these arts can only be acquired by many years of constant endeavor, he thinks that for persons destined for an artistic career, it is necessary, instead of sending them to college, to hurry them through such instruction in "their native tongue, arithmetic and other simple studies" as they can acquire before the age of fifteen, and then set them at the manual practice of their chosen art under a good master, "all day long and every day," "until the master finds that his apprentice has grown up to his own stature." After this, Professor Sturgis says, "If the university should wish to teach this artist in his later life, when the young man, already a master in his art, feels the need of more literary cultivation than he has had hitherto, then, to his mature mind, and his faculties of perception and acquisition trained, though not in the literary way, the university may offer literature, language, science,— what you will." "It would be a noble thing," Professor Sturgis continues, "to have such a course of collegiate studies for the grown man. On the other hand, nothing but injury to the artist's career can come from anything like a serious attempt to teach him any of those things which are contained in the language of words during the years which he should devote exclusively to his artistic training."

IT would not be easy to state a position in clearer terms than these, and the community has reason to be grateful to Professor Sturgis for giving to the discussion a perfectly definite form at the outset. We need not say that no university would pretend to take boys of eighteen, and in four years turn them out accomplished artists, so that the question is not whether college training or a long apprenticeship is the best preparation for an artistic career, but whether one excludes the other, so that the man who has spent, let us say, six years in his university course, and in the preparation for it, is thereby cut off from the hope of ever acquiring the manual skill necessary for the successful practice of the graphic arts. In answering this question, while we have Professor Sturgis's own weighty opinion on one side, supported by that of Mr. Ruskin, who declares that to color well "requires your life,— it cannot be done cheaper"; it seems to us that there is a great deal of evidence in favor of the opposite view. It is always difficult to say what a man might have accomplished if his training had been something else than what it was, but every one will recall the names of many successful artists trained in the universities, and trained, too, at a time when university training did not include the slightest trace of the artistic cultivation which Columbia University proposes to afford its students during the four eager and susceptible years of their college life. Not even Professor Sturgis can deprecate more earnestly than we do the old American fashion of talking about the arts, instead of practising them; but this fashion is rapidly passing away, and the American artist of the present day understands as well as any one that he must make his impression upon the world with his brush or chisel, and not with his mouth. With this conviction, aided by the wholesome competition which now exists, not only between American artists among themselves, but between them and the French and English and German artists whose works are hung beside theirs at the great international exhibitions, the painters and sculptors who will, in the next generation, represent this country are not likely, as it seems to us, to be injured by college training, but the reverse. It is very possible that the loss of continuous manual practice during a part of four or six years may show itself in the work of a college-trained artist; but it seems to us that this loss will be more than made up by the greater power of mental concentration, the deeper sympathy, and the simplicity of taste and dislike of affectation, which are cultivated, if not developed, by university life. No one has more frequent occasion than the artist to observe how greatly the hand is influenced by the mind. A strong impression of beauty of form, or color, or expression will betray itself even in the work of an unskilled artist, as multitudes of specimens of archaic painting and sculpture show us; while mere handling has never brought more than temporary fame to an artist of cold heart, or of dull and irresolute mind. There is still a tendency in the arts, a survival, possibly, from the artificiality of the seventeenth and eighteenth centuries, to exalt technique at the expense of sentiment. Professor Sturgis himself shows something of this tendency, perhaps, when he says, of an art more familiar to our readers, that "architecture as practised in modern times is not a manual art, but is a combination of an intellectual but non-artistic study with science, and with artistic traditions now embodied in books"; and we hope that

Entered at the Post-Office at Boston as second-class matter

some, at least, of our readers will agree with us that this tendency, now happily going out of fashion before the tide of life and aspiration and conscious power which is advancing over the American people, should be resisted by all who desire to help in the development of the fine-arts which will surely follow. There is no place where true sentiment finds a more congenial home, and where conventionality and affectation are more uncomfortable, than in a university; and we hope and believe that in this way, if in no other, our great colleges will be able to take an important part in the movement which lies so near the hearts of all American artists.

AN interesting question has come up in connection with the Boston elevated railway, in a suit by an owner of a house on Harrison Avenue for damages sustained from the construction and operation of the road in front of the building. The claimant asks for compensation, not only for the darkening of his windows, the dust raised by the trains and the annoyance caused by the moving lights at night, but for the noise caused by the traffic. On the other hand, although there is no doubt that the Boston elevated railway is a very noisy affair, the corporation holds that its charter, interpreted in connection with the general statutes of Massachusetts in regard to railways, protects it from claims for damages on this score. The question is exclusively one of law, but the decision will be awaited with interest by owners of real-estate on the line of the road, as well as by the public. In fact, the interest of the public is, perhaps, greater than that of abutting owners, for juries, where, as in the present case, a man's rents have fallen off six hundred dollars a year since the building of the road, would be likely to award him suitable compensation on general principles, without inquiring how much of the loss was due to noise, and how much to dust and darkness; while the public, which has no claim to damages, suffers much more from the noise than it does from the dust and the moving lights of the trains. In many ways the engineering of the Boston rapid-transit lines is worthy of highest commendation, and for the benefit of the community, if not of the railway corporation, it seems as if something might be done to mitigate the deafening racket which attends their operation.

CERTAIN excavations made in the basement of the old New York Hall of Records have brought to light some interesting historical evidences. The building was erected in 1756 as a debtors' prison, but twenty years later, when the city was occupied by British troops, it was appropriated for military purposes, and was used for the confinement of prisoners of war. It was placed particularly in charge of the Provost Marshal, Cunningham, and was called the Provost Prison, to distinguish it from the sugar-houses and other buildings, and the hulks in the harbor, which were utilized for similar purposes. The horrors of the prison-ships have been often described, but Cunningham seems to have done his best to make his Provost Prison as uncomfortable a place of residence for captured "rebels" as the rotten hulks anchored in the harbor. Among other devices which he employed for disciplining his prisoners, among whom was for a time the brave Ethan Allen, was a "slow gallows," provided with a noose which tightened very slowly around the neck of the sufferer, so as to prolong his agonies. The room in which this instrument was placed is still intact, as are also several other underground cells, in one of which can still be seen the cavity made in the brick wall by some Revolutionary prisoners, who attempted to escape in this way, but were discovered, and all executed by the "slow gallows." Their bodies are said to have been buried under the cellar floor, and the workmen employed in the present repairs have actually dug up bones, apparently human, which have been, of course, carefully preserved by the authorities. On the completion of the new Hall of Records, the old building is to be used as a Revolutionary Museum, for which it is well adapted.

THE perennial discussion of the best methods of metallic construction has been given a new turn by the appearance of a letter in the *Scientific American*, from Mr. George L. Morse, a well-known expert, earnestly advocating a return to the old-fashioned cast-iron columns in buildings, in place of steel. He says, of course with reason, that cast-iron columns are not only cheaper, but are less liable to corrosion, and much less readily affected by heat; and he surmises that the greater familiarity of engineers with steel, as used in bridge and girder work, may have led them into a preference for the material about which they know most which is not quite justified. He observes that with high, narrow buildings, in which wind-bracing is necessary, steel verticals must be employed, as wind-bracing cannot easily be applied to cast iron; but under ordinary circumstances, he thinks it very desirable to use cast-iron columns in exterior work wherever possible.

AS this is a view of the matter which comes up every few years, and is, of course, eagerly adopted by contractors, who understand perfectly the difference in price between steel and cast-iron, it may be well, from the practical standpoint of the architect, to observe that the periodical removal and abandonment of the use of cast-iron for verticals has been due much less to the ignorance of engineers and architects of the properties of this material than to the conviction born of their experience, that it is, in most lofty buildings, unsuited to the conditions. Mr. Morse says that cast-iron columns cannot be used where wind-bracing is necessary; but bracing is practically needed in every building over six stories high, not merely to protect it against the effect of wind, but to prevent the racking which may occur from a great variety of causes, as well as to give security against those variations of the frame from true vertical lines which, a few years ago, used to occur so frequently, and which are so detrimental to the strength and endurance of the construction. Again, while good cast-iron is an excellent material for many purposes, bad cast-iron is a very poor material, and it is much more difficult to detect flaws in cast-iron columns than in steel ones, while a defect in a cast-iron vertical, perhaps with twenty stories resting on it, similar to the defects which have brought down hundreds of cast-iron columns under a comparatively trifling load, might have terrible consequences.

MR. WILLIAM BARCLAY PARSONS, the Chief Engineer of the Rapid Transit Commission of New York, proposes an interesting plan for the relief of the congestion of travel over the Brooklyn Bridge. The plan, which is approved by Mr. Lindenthal, the Commissioner of Bridges, is, in brief, to change the grades of the railway-tracks on the bridge and its approaches, so that the cars, instead of starting from the street-level at Park Row, will be underground at that point, continuing thence by tunnels northward and southward, the northern tunnel extending to the new Williamsburgh bridge and returning to Long Island over it, and the southern tunnel extending to Maiden Lane, and thence, under the East River, back to Brooklyn; the tracks thus forming two loops, one to the northward, and the other to the southward, tangent only in the portion crossing the bridge; so that both the trains and the trolley-cars cross the bridge only in one direction, the trolley-cars returning to Brooklyn through the Maiden Lane circuit, while the trains return by the Williamsburgh bridge. Mr. Parsons's plan contemplates a station on Park Row, adjacent to the Rapid Transit station, so that passengers from the upper end of Manhattan Island may step directly into the Brooklyn cars; and he also proposes to erect on the site of the present Manhattan bridge terminal, facing west over the Park, an important municipal building, with archways under it, through which foot-passengers and ordinary vehicles can reach the bridge.

SOME of our Western grain-growers might take a hint from the German farmers, who have formed an extensive association to protect themselves against oppression from corporations. As every one knows, the sugar-beet is one of the principal products of German farms, and from the sugar-beet is made alcohol, as well as sugar. A combination has long existed between the great sugar-refiners, which has enabled them, not only to control the market for refined sugar, but that for raw sugar and beets, inasmuch as the farmers, having practically no customers outside the combination, are obliged to sell to the latter at its own price, or to have their beets left on their hands. In the matter of alcohol, which is made from the inferior beets and raw-sugar wastes, the farmers have been wise enough to join in the formation of a "cartel," similar to that existing among the owners of the German coal-mines, by which prices and output are regulated for the common benefit, at the same time that the members are protected against the dictation of monopolies. The plan has proved so successful that it is not unlikely that similar "cartels" may be formed to regulate the sale and production of other agricultural products; and our wheat-raisers, who are said occasionally to suffer from combinations of millers and exporters, might do well to watch the proceedings of their foreign brethren.

THE ROMAN GALLEYS OF LAKE NEMI.

WHEN, from the top of one of the surrounding hills, one's glance sounds the clear waters of Lake Nemi, one perceives a mass of confused forms, with rounded contours and indistinct lines, and divines that they are drowned objects sleeping there from the times of the grandeur of Rome in the crystal liquid of the "Speculum Dianæ." They are lying there patiently in their dress of sea-weed and mosses until the indolent posterity of the conquerors of the world pluck them from their repose to ask them to throw light on that departed civilization which has left them there.

In fact, this volcanic shell with its luxuriant vegetation, this placid and sombre lake, sleeping in the midst of the thick and encircling forests, this amphitheatre of hills, these almost perpendicular gradins covered with bushy trees through which, here and there, penetrate imposing cliff-fronts burned by the sun, this oval lake of Nemi, is, in a word, one of the corners of Latium where there is still vigorous the memory of the glorious age of Rome; and it is a veritable amphitheatre whence, at times, there appears to ascend a mysterious influence. Ilex and chestnut crowd together on the banks, like spectators motionless on the gradins through waiting centuries; in a corner below the village, the orchards flower in the springtime with the thousand rose-tinted stars of peach-trees, the white constellations of the apple-trees, and these gay tints cut across the melancholy green of the trees as in the Roman circuses the podium of the vestals must have stood out athwart the pressing and vulgar crowd of spectators. Here is a flagged path over which, in former times, the litters of the Roman matrons used to pass in going to consult the Oracle of Diana, for this lake, these forests and these mute cliffs, the thick shadows and lively colors of this countryside were only the crown of the temple of the goddess of the woods and chase; it is here that the dynasty of autocrats, who formed the veritable expression of the limitless power and frightful wealth of the Roman Empire, at the same time that they condensed in themselves all the faults and vices which brought about its decadence, used to come to enjoy a spectacle of which nature had borne all the cost. Sumptuous villas once lined the shores of the lake and rose stage over stage above the surrounding slopes; treasures of art came hither demanding a framework from this incomparable landscape; the very water cradled palaces and floating temples.

When the pitiless decadence, the barbarous fatality broke the last energies of the Latin world, everything here fell into ruin, was destroyed and rotted away, forgotten, buried under the fertile soil or beneath the placid waves. It only needs to remove this earth, to sound with one's eyes these sleeping waters, to discover the remains of an epoch, its *spolia opima*, its rich objects and its imperishable souvenirs.

Museums have been enriched with findings which have been made in the environs of Lake Nemi. Beneath the slime and under the moss, treasures have already been found; but what was not the surprise of the world of artists and savants when it was announced, a few years ago, that two floating houses had been seen sleeping a few metres beneath the water's surface, and with what impatience were attempts made to bring them to dry land!

You were probably informed of this occurrence at the time, as well as of the discovery of certain artistic bronzes belonging to the mysterious ships sunk to the bottom of the "Speculum Dianæ." But difficulties without number speedily presented themselves, which caused the abandonment of the attempt to save these ships; silence would doubtless have fallen definitely upon the matter in spite of the great interest in it, if, recently, one of the engineers who had a share in the first researches had not been overcome with remorse because of so complete an act of forgetfulness and had not once more brought forward the matter of the galleys of Nemi, and suggested a new scheme for bringing about their salvage, a system which offered far less difficulty than those which had been attempted earlier under the impulse of feverish impatience.

I hasten to tell you that there is some chance that a decisive effort may be attempted to recover these rich relics which I mention; riches of inestimable artistic worth; for, apart from their rare sumptuousness, these floating houses surely represent a marvel, unique, which stands out from among all those memorials of our ancestors which up to this day we have discovered. This is not a palace, a temple, a public building, it is not a new example of Roman architecture, but it is a unique specimen of Roman naval art. Our King, Victor Emmanuel III, has just examined the scheme which would allow, as I have just told you, the bringing of these ships to dry land. He has shown himself disposed to accept the patronage of the committee which has this end in view. For the rest, here is a short description of what this new scheme is: —

Until now, the investigations have been carried on by divers who have studied the positions and dimensions of the two ships, and all that has been discovered has been owing to their efforts. But one fact had been discovered which made the saving of the ships almost impossible without lowering the level of the whole lake, and this fact is that they are in a large part buried in the mud, which has, as it were, riveted them to the place where they sank. Now, a sufficient lowering of the level of the lake presented almost insurmountable difficulties; so, for the moment, they were about to renounce all hope, if a new discovery had not turned up a short time ago which completely changed the situation. The lake of Nemi, like its neighbor, the Lago Albano, both enclosed in ancient craters, has an outlet pierced in the flank of the hillside which allows the overflow of its waters. You doubtless know under what historic circumstances, during the siege of Veii, the outlet of Lake Albanus was pierced; as to that of the lake of Nemi, there is the most complete ignorance as to its origin. But now we know that it is of a comparatively recent date, for another outlet, at a lower level, and still in good condition, has been discovered. It would be sufficient, then, to remove the matter which obstructs this ancient outlet, and, in parenthesis, besides the fact that in this way the two Roman ships could be saved, one could at the same time dry off the site of the ruins of the villa which Julius Cesar had built on the shores of Lacus Nemorensis, and which were covered by water after the level of the lake had been raised by the change in the level of the outlet.

A tradition prevailing among the inhabitants of the village of Némi, built almost perpendicularly above the lake, has always maintained that Roman galleys did exist beneath the waves. One circumstance confirmed this popular notion and the legends which prevailed for centuries, and that is that fishermen casting their nets to take the delicate fish which breed in quantities at the bottom of the lake have often had to abandon the attempt to bring their prey to the surface because the nets became entangled amongst obstacles which at first were of an unknown character. It was, therefore, approximately known about what spot in the lake must be sounded in order to discover these ships, for there was only one obstacle which could exist at such a place. Sometimes, moreover, bits of rotten wood were torn away and brought to the surface.

About the middle of the fifteenth century, Cardinal Prospero Colonna, Lord of Nemi and Genzano, two villages staged one above the other upon the hillsides which surround the lake, had had his imagination impressed by the tales which were current among the peasants; the legend, according to which the relics of the richness of the Roman emperors were rotting beneath the waters, seemed to him all the less ridiculous because he was so thoroughly versed in Greek and Latin letters and the arts; consequently, he would not have been at all unwilling to have his name attached to an enterprise which might assure him an imperishable glory. It must be remarked in passing that as for these sentiments, although any one of reasonable intelligence might hold them to-day, they were at that time really meritorious, for then the cult of antiquity was hardly in fashion or held in honor; the noble monuments of Rome had undergone numberless vicissitudes without finding in the popes and the lords of the aristocracy friends anxious to preserve for posterity these precious relics; the tomb of Cecilia Metella, the theatre of Marcellus, the Colosseum, the baths, the mausoleums, all that the barbarians had respected, were no more than fortresses about which the princes waged wars whose bloody struggles discolored Rome; and, when peace followed the civil wars of the Middle Ages, every ancient edifice was held to be merely a quarry from which any one, provided he was strong enough, could carry away bits of stone to build his dwelling, statues to decorate his palace and columns to adorn his churches. In short, this was the time when the Palazzo Farnese was built, and the Barberini and Cancelleria, and so many others, out of stones coming from the Colosseum, times when they overthrew a pagan temple in order with its precious marble columns to ornament a Catholic church.

Unfortunately, Cardinal Colonna, in spite of his wealth and learning, had not the means and apparatus adapted for so difficult a piece of salvage as that of the galleys of the lake of Nemi. He had to content himself with bringing from Genoa sailors of miraculous cleverness, capable, as it appears, of living beneath the water for minutes at a time, and swimming like veritable fishes. These past-masters in the art of diving set themselves at work and were not long before they definitely proved the existence of two large sunken ships. They even tried to save some portions of them, but we cannot too much felicitate ourselves that their efforts were not pushed with perseverance, for their means and methods were of the most primitive kinds. They dove to the bottom and fastened to the wood of the structures which they wished to raise great iron hooks made fast to ropes operated from the surface. One portion of the prow of one of the galleys, however, gave way and was brought to the bank.

All the wise men of science and letters in Rome, and Pope Pius II himself, hastened incontinently to the place. An author of the time has transmitted to us a recital of the astonishment which this learned assembly exhibited before such a "find" and a description of the bit of the prow plucked from the ship. "It was composed," says he, "of big planks, 3 inches thick, of the wood named larch-wood; it was covered all over with a good coating of yellow or purple, and upon this were fixed with thick bronze, not iron, nails a large number of leaden plates."

Another discovery of the time was that of the leaden pipes which brought to the ships fresh water from neighboring springs. It was understood from these things that one was really in the presence of two floating houses, two lacustral palaces rather than simple galleys; and these leaden pipes bore inscriptions from which could be deduced that which tradition already affirmed; that is to say, that these submerged dwellings had been built by Tiberius. All these objects were disposed of, we now do not know how or where; they have never been rediscovered in our time.

A century later another attempt was made. A certain Francesco de Marchi, a Bolognese soldier, this time himself descended to the bottom of the lake, using one of the rudimentary instruments which

allowed him to breathe for a certain length of time under water. We don't know quite what this instrument was, for De Marchi left only an incomplete description of it, in which he simply said that the invention was due to Maître François de Lorraine, and that the latter had made him swear never to reveal to any one by what mechanism the renewing of the air was effected.

De Marchi details his discoveries at length, but it seems to be plain from his tale that he made only a single descent of any length of time — an hour — during which he bound together and had pulled to the surface a large quantity of beams and planks of cypress-wood and pine. He said that he saw great iron rails eaten by rust, small bronze nails which fixed leaden plaques over the bottom, and brought away portions of the brick floor, 3 spans wide in each direction and 4 inches thick, also another portion of flooring of a beautiful red enamel. He also saw chambers in the interior of the ship, and leaden pipes, but nothing of what he brought to dry land remained, for robbers, thinking that they were stealing the secret of his submarine machine, carried away everything.

Another spell of silence, this time lasting for three centuries. But tradition was not going to abandon its belief after the experiments which we have spoken of had proved the existence of the vessels, whether they were built by Tiberius or by some other emperor.

Finally, on the 10th of September, 1827, Chevalier Annesio Fusconi made a new attempt. He employed a diving-bell invented by Dr. Halley, and this instrument stood for an immense advance, since eight workmen could work at the same time, receiving air through a pump placed on a raft above. This is how Fusconi tells the success of that day's work: —

"The workmen descended in the diving-bell, and after a short time gave the signal agreed upon; we pulled them up, and they brought us, amid the unanimous applause of those present at the operation, bricks framed in iron with the inscription 'T I B. C A E S,' and several metal nails." Later success did not give the lie to this first descent. "We did the same things on the following days up to the 28th of this month, a date at which a round metal object, which the workmen could never properly describe, was made fast to be pulled to the surface, but the ropes gave way."

But once more the robbers appeared, for, during the winter, the investigations were suspended, and they seized the apparatus of the unfortunate Fusconi. Let us pity the misfortune of this generous man who had paid out of his own pocket 30,000 francs for the construction of his machines. But it must be agreed that the proverb "Misfortune is good for something" has some truth in it, seeing that Fusconi, in his ignorance, proposed simply to draw the vessels from the water bit by bit, believing that it was impossible to recover them whole. The objects which he had discovered were those which his predecessors had seen: bits of wood, nails, leaden pipes, and, moreover, a bronze capital, marble tablets, a fragment of grille-work bearing the inscription "T I B. C A E S," and forty large bricks of terra-cotta, two of which were framed in iron, as were those described by De Marchi. Fusconi also said that his workmen saw at the bottom of the lake statues, columns and metal beams which could not be drawn out of the water because the cables would not stand the weight and broke during the operation.

A large portion of the objects recovered at this time were purchased for the Academy of St. Luke by Cardinal Camerlingue.

. . . . . .

All that precedes relates to efforts made in the time of the government of the Popes to save the Roman galleys, but the great political changes took place after 1827, the time of Fusconi's explorations, and new obstacles were created, while science considerably minimized those obstacles which caused the failure of the attempts made up to that time.

The rights of the State in artistic treasures have been recognized for a long time; the Pacca edict against the exportation of anything which might have the character of a work of art was the first affirmation of these rights and dates from the commencement of the nineteenth century. Later, when Italy was organized as a single kingdom, the *régime* of objects of art was definitively fixed, always in a manner favorable to the State. This brought it about that every private attempt at saving the Roman galleys encountered insurmountable obstacles. The State claimed its rights in any objects which might be discovered, hindered all speculation in their value, and especially prevented their exportation. No one, therefore, was inclined to cast into the water enormous sums for the good pleasure of the Italian Government, who, on its side, is generally thinking of other things than archæology. On the other hand, the lake of Nemi is private property, one of the fees of the very ancient patrician house of the Orsini, and this fact made it impossible that any one should undertake to investigate the galleys without the authorization of Prince Orsini.

In any other country, let us say in passing, both government and prince would perhaps have been rivals in their ardor for the recovery of the Roman ships, if it were only for the sake of having their names attached to an enterprise capable of making its author forever celebrated; but here it was quite otherwise. In 1895, a Roman antiquary was making some excavations in the neighborhood of the lake and particularly on the very site of the famous Temple of Diana and had the idea — which may have been suggested to him — of seeking by skilful sounding the exact position of the galleys, with the hope of saving at least some parts of them. He entered into a contract with the Orsini family in which he bound himself to attempt at his own risk and peril the necessary researches, and had them begun at once by a diver at the point indicated by tradition and the earlier explorers as that where the Roman galleys had been rotting for centuries.

The results of these attempts are known; it was an unexpected revelation, a very thunderclap. Much was spoken at that time about the marvellous bronzes of Lake Nemi, and especially of the bronze head of Medusa, a piece which far exceeded all that any one had hoped for in the way of the splendors of these floating palaces. How many artists of the Renaissance, even the greatest ones, would have been happy to sign their names to such a morsel! This head is treated with great skill; the beauty of Medusa is heightened by the expression of atrocious suffering which she endures; the artist who created the bronze profoundly realized the misfortunes of this mythical personage and the terrible power which the gods granted to her as chastisement for her faults and pride.

The archæologists were equally interested in the bits of enamelled work and vitrified compositions which evidently belonged to mosaic floors. This mosaicwork seemed to form an "*opus sectile*," that is to say, a pavement composed of marbles of different colors, cut in shapeless pieces of regular size fitting one against another, so that when everything was in place designs and figures of the most beautiful effect were produced. This rich "*pavimentum*" is more beautiful and richer than those famous ones which are found in the palace of Caligula on the Palatine.

Such was the success of the investigations carried on about the first galley. But the existence of a second one could not be doubted because of the attempts made in the earlier centuries, so they came upon new discoveries, the most important of which was a bronze hand resting upon a plaque of the same metal and which was apparently a "*manus averrunca*," that is to say, an amulet against bad luck, which was ordinarily placed at the stern of ships to attract favors and the protection of Fortune. This "*manus averrunca*" must have belonged to an epoch earlier than that of the bronzes of the first galley; it is by the rigidity of the forms and the harsh lines of the fingers that the archaic character of the bronze is recognized.

But the Italian Government, fearing that the antiquary who had undertaken the partial salvage of the ship might do damage in his attempts to get hold of some of the objects of value, laid an injunction on him, and ordered that an official inquest should be held to study above everything the position and the dimensions of the galleys in order that later they might determine the most practicable way of raising the vessels from the water. The inquest, which was entrusted to a naval officer and some divers from the Government arsenals, gave the best results and the most exact data: the first galley is 20 metres from the bank; its length is 64 metres, its breadth 20; the stern is at a depth of 5 3 metres; the prow is lower, being 12 metres below the surface; the broadside has given away about the centre for a length of 3.4 metres. The second galley lies 50 metres from the bank; its length is about 71 metres, its width 24.4; its stern lies at a depth of 16.6 metres, and the prow pitches towards the centre of the lake to a depth of 22 metres. This galley has given away for a length of 2 metres on the starboard side. The distance between the two galleys, from centre to centre, is about 200 metres.

It must be noticed that these investigations have had to be carried out on a steeply inclined bottom, since there is a difference of about 17 metres between the stern of the first galley and the prow of the second, and there is some apparent probability that a certain number of the ornaments, furniture and utensils which were aboard may have slipped down to still greater depths. The hulls of the galleys, as I have said above, are not entirely free; the first is almost wholly submerged in mud and slime; there is only the upper portion of the deck which is free. A deck seems to start from the stern, which has a peculiar form like a fan, towards the centre of the ship. The second hull emerges from the mud for a length of about 40 metres, but the stern is completely covered; the interior, however, seems empty.

The manner in which these galleys were built, a manner which caused the liveliest wonder amongst the first divers, deserves to be briefly described. Planking is fixed to the framing by copper nails; they are lapped and held in place by long bolts; moreover, they are made fast on the inside by pins of resinous wood. The planking is covered with a compact cement over which is stretched some thick woollen stuff. And, finally, everything is protected by the plates of lead which we have mentioned.

Now let us turn to the methods which might be used in the salvage of these vessels. There are two distinct methods: first, the absolute hoisting of the vessels from the water, and, second, the lowering of the level of the lake. The first method would be preferable; for the lake of Nemi being one of the most picturesque in Italy, affording a landscape of extremest beauty, that artists and foreigners who come to Rome hardly ever miss visiting, it would be a great pity to remove one of its decorative features, this little pool of tranquil water, the "speculum Dianæ," which really forms its chiefest ornament. But for the system of direct hoisting, it would be necessary to construct a small city on rafts above the vessels and clean away in some degree the bottom of the lake in order to remove the mud, and then, possibly, slide ropes under the hulls and set in motion cranes of great power. All this presents a very grave inconvenience. Almost all of the objects of art which used to form the riches of these galleys have slipped out of the hulls and now lie buried in the slimy mud at the bottom. One would run great risk, therefore, of withdrawing from the water only the carcasses of the galleys, to say nothing of

the difficulty of saving them whole. The engineers could not gather a very exact idea of their position and the force of the resistance which would be opposed to the cranes, and the least error in the distribution of the strain, which ought to be regulated according to the weight of that portion of the ship to which it is actually applied, might compromise the outcome of the enterprise.

They are thinking of making a decisive attempt which may be crowned with the most startling success because there has been discovered, as I said above, an outlet at a lower level than that through which to-day the lake discharges its overflow, and which is in a better condition. This is Roman work, a long tunnel with a considerable section, measuring 1.6 metres by 1 metre. All that would have to be done would be to clean away obstructions and through the cleared outlet the level of the lake could be lowered by 9 metres. Then they would build at its mouth the short arm of a siphon, dipping below the water, and through it successive layers of water, which still covers the floating houses of Tiberius, could be sucked out of the ancient crater.

As you see, this scheme is fairly practicable. The cost of the undertaking would not be enormous, and what would be a very great advantage, and practically the one condition under which these famous vessels can be saved, is that the work would be done, as it were, on dry land.

This is what they are undertaking to carry out, a campaign which has long been the dream of Italian and foreign archæologists, and it would be very helpful if the King should decide to accept the patronage of the committee which is going to be formed. He is young and bold, and has already given proof of a high degree of erudition. He cannot fail to be interested in the events we here speak of.

Already there is talk of erecting a Roman naval museum where might be deposited these Roman barques and all the ornaments and rigging which might be recovered. This would be one more attraction for Rome, and one can feel certain that it would be carried out with care and intelligence, for although in Italy things are undertaken with considerable sloth, yet, when they are undertaken, they are carried out properly.

H. Mereu.

TECHNICAL AND SCIENTIFIC BOOKS.[1]

"THOSE who are actively interested in engineering education cannot help but feel a certain sense of responsibility for the remarkable record of industrial development which the last few decades have made. For substantiation of such claim attention need but be called to the captains and other officers of industry who have been trained in the technical schools of the country. The inadequacy of the engineering education of thirty years ago for present conditions is scarcely more obvious than the fact that engineering education of the present will not suffice for the future. Present methods, continued indefinitely, would develop leaders, as they have done in the past, but the question of a debatable nature may be raised: Is the country better off with a few great engineers or a large number who are capable? Perhaps the most serious limitation upon engineering education at the present time is its failure to reach the rank and file of industrial workers, a limitation which is steadily increasing in degree. In spite of the fact that some of our advanced technical schools are free from tuition charges, it is evident that only a very small percentage of the inhabitants seem to be endowed with the privilege or opportunity of attending such institutions. It has been estimated that one per cent of the pupils of the grade-schools continue their work beyond the high-school.

"It seems to be the predominating idea at present that increase in efficiency of engineering education lies mostly with reference to the instruction of the favored minority who are able to attend technical schools. This is shown by the action of the leading engineering-schools in increasing the height of the barrier commonly termed entrance-requirements, thus more noticeably decreasing the percentage of those permitted to attend. A college education gives to its possessor an advantage over his fellow-men and almost ensures for him promotion to the more important positions, thus serving in a considerable degree to remove the less fortunate from the line of promotion. This stratification which appears to be developing, placing the technical graduate in the upper layer and creating an engineering aristocracy, is to be deplored as contrary to the American doctrine of equal opportunity for all. By the very progress of the technical graduate the outlook for the shop-man or machine-laborer is darkened, for, seeing the higher positions apparently closed to him, he will lose that incentive which is the underlying foundation of American enterprise, hope of advancement. He will feel that he is born to a position in life from which he cannot rise. The solution of this problem as to how such condition may be avoided is perhaps the most difficult and important task which those interested in technical education have to undertake; but there is no doubt that American ingenuity will find a way of satisfactorily solving this, as it has done other great problems. Various experimental solutions are now under trial and others have been proposed. Among the former are the so-called correspondence-schools, summer-schools for artisans, which at least one of our universities has instituted, night-schools, classes conducted by the Y. M. C. A., instruction offered by manufacturers, and various other methods, each of which has its own advantages and disadvantages which it is not my purpose to discuss.

"The great school for the industrial worker is the shop or the factory. The worker in this school is in a laboratory of the most efficient sort, in which he can develop efficiently, if he will develop, his brain, together with manual skill and dexterity. The workman must first be taught to realize that unthinking skill can never hold its own against brain-training. After instilling this feeling, every possible opportunity should be given to make the work of brain-training as simple and efficient as possible. The correspondence-schools, in having enrolled over a quarter of a million students, have demonstrated the state of intellectual hunger which prevails among the industrial workers of the country. In addition to demonstrating the existence of this hunger, at least some of the schools have done much toward satisfying the same. The proficiency of the industrial worker lies largely in his knowlege of the laws of nature and their applications and limitations, and an ignorance of such laws determines to a large extent the difference between the mechanic and the engineer. Such laws and applications may be learned from books, and in this fact lies the opportunity which the libraries have for furthering industrial progress.

"There are various ways in which the librarian's work may be to the advantage of engineering education, by which term is meant the dissemination of knowledge which bears upon and influences industrial development. The library may supply such scientific and technical literature as will meet the requirements of those who wish to use the same for recreation or for general information, and therefore including writings of a popular nature. The library may stimulate interest in scientific and technical matters among high-school students and others who are to choose their life's work. The means may also be offered to technical men for continuing their studies, or in carrying on investigation, for which purpose a good reference equipment is requisite.

"The library, in placing at the disposal of the workman-artisan class the literature best suited to their needs may accomplish results of inestimable value. 'The vast number of workers, so important to the future welfare of the Republic, deserve and are in need of more consideration and encouragement for self-education than are those who constitute what are known as our educated classes.' It is to the means of giving aid to this class that I wish especially to point. Libraries have been and are at the present time very inefficiently dealing with this matter, the following remark recently made by a prominent technical man emphasizing this point: 'Instruction in engineering literature is not organized, it is not looked after, it is not cared for, yet it is one of the most important questions. On entering a modern public library one finds excellent reading-lists upon almost any topic in history, art, literature and some science, but none on engineering or technical subjects.' A study of methods of increasing the efficiency reveals some of the causes of inefficiency, principal among which is the lack of a sufficient number of books, and, what is equally harmful, the presence on the shelves of books whose influence is not only indifferent but actually harmful.

"Certain branches of engineering and science, especially those capable of spectacular treatment, have been subjected to a flood of literature during recent years. The greater part of such literature, in spite of popularity as shown by calls for the same, is not only unreliable and worthless, but is actually harmful and a hindrance to true progress in engineering education. It is to be deplored that those who represent the most advanced learning in their profession seldom indulge in the writing of elementary books, since the financial reward for such work is not comparable to that which may be received in more strictly professional work. The writing of the elementary book is therefore left to the amateur engineer. The public demand may seem to make it necessary to place many undesirable books on the shelves, but it seems to me that just as much care should be used in barring misleading books in science and engineering as in excluding those which are detrimental from the moral standpoint.

"In arguing for the organization and more efficient operation of scientific and engineering departments in the public library, with the view of helping especially the working-class, I am well aware that nothing new or heretofore untried is being presented. I will anticipate some of the objections which may be raised against this system for industrial betterment. It will be argued that certain libraries have maintained technical departments at considerable expenditure of capital and labor, but that little interest has been manifested in the same by the people who were to be benefited. It is true that only a small percentage of the industrial workers seem to have an ambition to rise, strange as this statement may seem, and even if possessed of such, few have the enterprise to do the extra work necessary to further this ambition. The results, however, which can be effected by ministering to the requirements of those who have both ambition and enterprise, even though such number be small at present, is a sufficient argument for carrying on the work. In this way the library may serve as a net spread wide to catch the talent which the country produces.

"It may be said that manufacturers have installed libraries in connection with their works, and have even offered free instruction to their employés. The indifferent success which such attempts to improve the men have met points to possible failure for public libraries, if they take up this work. It has been a matter of common experience, however, that advantages such as gratuitous instruction offered by employers are seldom appreciated by employés, for the majority become suspicious of the intentions, feeling that such efforts are being made in the interest of capital rather than of labor. To the library this is a matter of less moment, for the public may be

[1] Portions of a paper by Prof. C. F. Burgess, of the University of Wisconsin, read at the Annual Convention of the American Library Association, June 20, 1902.

made to have a feeling of ownership, which is synonymous with a feeling of interest. There may be means whereby the library may increase such interest. An experiment with this in view is to be tried by the public library at Madison, Wis., during the coming winter. It is proposed to have a series of informal talks, or lectures, given to the employés of local factories upon technical subjects which may be of interest to them, a small charge to be made for the course. The proceeds are to be used for the benefit of the technical library, books and periodicals being purchased which will be of most service to the contributors. Experience has shown that a free course of lectures will not retain the interest of the audience as will a course in which money is invested, and in addition to retaining such interest, it is thought that the investment of the proceeds as before mentioned will increase the interest in the library. The lectures are to be given by local engineers and professors of the College of Engineering of the University of Wisconsin. Almost any public library can easily get up such a course of talks, as the technical men of the community will readily lend their assistance.

"The library to be a place of study requires a good list of reference-books and journals. Current technical and trade-periodicals would be a drawing card, and those who possess, even to a minor degree, the ability of self-education, will find here their mental nourishment. In almost every industry there are now technical books and trade journals and catalogues of very high educational value which may be acquired at a very small cost. A most valuable part of engineering and scientific literature is in such publications, and with bound volumes of the same the librarian might readily compile reading-lists for those who desire to look up any particular line. By suitable scientific instruction the usefulness of the industrial worker to society is increased, his horizon is broadened, the dignity of his calling is developed; and no other agency seems as universally suited for furnishing such instruction as does the public library."

A NEW YORK STUDIO.

HWAY up above the bustle of the street on the corner of Sixth Avenue and West Fortieth Street is a suite of apartments that, to say the least, is a novelty in New York. Mr. A. A. Anderson, an artist, who for many years presided over the art-colony at Paris, has erected on this corner a building known as the Bryant Park Studios, of which Mr. Charles A. Rich was the architect, and while laying out the whole building for the exclusive use of artists and art-patrons, he has therein built a suite for himself as an example of what he deems a studio should be. Choosing for himself the westerly side of the building, across the north ninth and tenth stories for his entrance, and the whole of the upper central part for his working-studio, the whole suite shows the perfection of plan which is possible with a thorough knowledge of the needs of an artist.

Entering a small private hallway one is admitted to the private living-suite of the owner, which contains also a small studio. The first room is the reception-room, a most perfect example of Louis XV decoration. The walls are moulded into panelwork of pure white, having the ornamentation of most exquisite design, with the large emblematic centre cartouches of raised work in low-relief. The ceiling, also laid out in panels of refined design, is elaborately ornamented in relief, and the doors are carved in the beautiful flowing lines of the period. All this ornamentation was made in Paris by Parisian workmen. Opening from this room is the chamber, also in the same style, of simple design, with marble mantel, circular ceiling ornamentation, and walls covered with delicate French silk in upright stripes.

To the south is a bath-room of marble and tile.

Returning and passing through the reception-room, beyond is the small studio, a room 25′ x 25′ in size and 20 feet high, in the style of Francis I. The room is formed by dark oak panelled wainscotting 10 feet high, with an ornamental carved band-course for its capping, above which the room is again panelled off by rich dark green tapestry in oak framework.

In carrying out the style of the room the ceiling is composed of very deep and very thin beams only a few inches apart, these beams being decorated in gold. The effect of this room is exceedingly beautiful and is strengthened by the large columniated mantel, richly carved, which runs to the ceiling, and is flanked on the opposite side by a hanging balcony with carved balustrade. Spanish tapestries from Salamanca drape this room, and the high studio-windows send down a flood of light from the top, and show another balcony with pierced railing which discloses the dining-room. Aside from the actual beauty of this small studio, its fittings are so arranged that backgrounds of the different periods may be properly set.

A hallway leads back through the entrance-hall, and we ascend the oak staircase and enter the dining-room from the second-story hallway. The room is strikingly beautiful, for it has a groined ceiling in dull gold which smacks almost of the feudal period, and the same spirit is carried out in the Gothic mantel with its pointed arched canopy. We look out from this room into the studio below, and passing along the balcony of that room approach the Grand Studio, which occupies the entire centre of the roof of the building, and from a promenade along the front of which we can look down upon the quiet green foliage of Bryant Park. This studio is 50′ x 50′ and 30 feet high. Its wall-surface is simply a quiet tone, as befits a studio, but its enrichments in the way of form and embellishment, while equally quiet, are rich in the extreme, and have been the sole study of Mr. Anderson. A large organ occupies one corner, under which is seen a glimpse of Damascus in all its Oriental splendor. A beautiful old entrance which once graced an Italian palace gives entrance from the other corner to a charming palm-garden, for which the rich golden doorway forms a framework setting off the soft greens of the shrubbery. Between these two features is a noble arch running to the ceiling, with balcony, draped with a gorgeous Beauvais tapestry, while a draped entrance beneath gives access to the private elevator.

But while the above seems to indicate mere luxury of surroundings, the perfection of the studio planning is apparent, for the entire north side, while admitting a flood of light, is controlled by a skilful arrangement of sliding-screens which will give any gradation of light, from the full clear light of a northern sky to total darkness. The entrance to this large studio has been made from a balcony off in one corner, so as to afford the best *coup d'œil* to one entering.

Mr. Anderson's pictures and portraits are everywhere about the room furthermore, and are evidence of his diligent work. While a most beautiful place, this studio of his is still a workshop where the study of years is made permanent by the hands of a man who loves his art and whose whole life has been given up to its study. L.

MODERN METHODS OF SEWAGE-TREATMENT.[1]

SEWAGE can be defined as the water-supply of a city after it has been used. It contains solid and liquid excreta, household waste, street-washings and the refuse of industry. The total amount of refuse varies, but on the average city sewage is pure water containing one-tenth of one per cent of waste; 7 pounds in 1,000 gallons. In addition sewage contains approximately 150 millions to the liquid ounce of those microscopic organisms called bacteria. Only very few are harmful to man, but in the perfect treatment of sewage bacteria as well as refuse must be removed. Perfect treatment of sewage, i. e., changing sewage back again into a water-supply, is possible, but at present not practicable on account of cost. All that so far has been attempted has been to remove the polluting substances, so that when emptied into a stream the sewage can cause no offence.

The earliest method of treatment, which was merely disposal, was to carry the sewage into the ocean or the nearest stream. This dilution is allowable for cities situated on the sea, or on rivers whose flow is as compared to the sewage 100 to 1, and the unfiltered water of which is not used as a water-supply. Very few cities are so fortunately situated as to make use of this method. For most cities the treatment or purification of sewage is as imperative as the obtaining of pure water. How this can be accomplished is one of the great sanitary problems of the day. The six principal processes in historical order are, sewage-farming, chemical precipitation, intermittent filtration, contact-bed treatment, septic-tank treatment, continuous filtration. Sewage-farming is applying the sewage to cultivated land. Chemical precipitation is adding certain chemicals to throw down the polluting substances. The four remaining methods, the so-called modern methods, are all based on the fact that the micro-organisms or bacteria always present in sewage will, under proper conditions, destroy all the obnoxious substances contained in sewage.

Sewage-farming; based on the idea that plant-life was capable of decomposing organic matters in sewage almost without limit, with resulting perfect purification and immense profit from making use of the polluting substances for plant-food, resulted in failure, except in those few cases where the land was of an exceptional character and of very large area.

Chemical precipitation, consisting of adding lime and iron sulphate to crude sewage and leaving the supernatent liquid clear of suspended matter, but containing practically all the soluble putrefying substances, is costly, and removes only about 55 per cent of the total organic matter in the sewage. The effluent will putrefy, and consequently cannot be emptied into a small stream, while the precipitate is difficult to treat, and is valueless. Sewage-farming and chemical treatment are now considered as methods of the past, and all the modern methods of disposal are the so-called bacterial methods.

The first of these methods was intermittent filtration. As early as 1865 Dr. Alexander Miller, of Berlin, showed that by passing sewage intermittently through sand, the obnoxious substances were removed, but the explanation is of much later date. It is now known that fresh sewage contains bacteria which live on dead organic matter and which cause its decomposition. These bacteria are roughly divided into two great groups, the anaërobic and the aërobic groups. The anaërobic group live, grow and multiply best out of contact with air and light; the aërobic live, grow and multiply only in contact with air. Each group plays its own special part in the destruction of the effete matter in sewage. The anaërobic bacteria act first. They disintegrate the solids, and bring them into solution. The aërobic bacteria act upon the disintegrated and liquefied compounds and, by oxidation, change them into harmless gases or minerals. Both groups of bacteria are necessary. By passing sewage intermittently through a suitable material, conditions favorable to the bacteria are brought about and the obnoxious substances are destroyed by the aid of these microscopic organisms. A suitable material was sand, and by applying the sewage only six hours out of the twenty-four, the conditions favorable to the action of both anaërobes and aërobes is maintained. By this process from 50,000 to 75,000 gallons of domestic sewage, not containing manufacturing waste, can be purified each day on one acre. Intermittent filtration is undoubtedly the best method known

[1] Portions of a paper by Dr. Leonard P. Kinnicutt, of Worcester, Mass., read before the American Association for the Advancement of Science.

for cities and towns which have in their neighborhood comparatively large areas of sandy soil.

It is not practicable for those which would be obliged to construct beds with sand brought from any distance. Investigations started by their problem seem to show that, by allotting distinct abodes to the anaërobic and aërobic bacteria, purification can be more rapidly carried on. The abode allotted to the anaërobic bacteria is called the septic-tank, that allotted to the aërobic bacteria, contact-beds or continuous filters. The septic-tank is only a modified cesspool, an open or closed tank through which the sewage is run continuously, but very slowly. The sewage itself contains anaërobic bacteria, which in the tank, out of contact of air, increase immensely, and bring about putrefaction, or fermentation, giving a product which is no longer crude sewage, but a sewage in which a large amount of the solid matter has been liquefied or changed into gas. The change which sewage undergoes in this fermentation process is very marked. The carbohydrates, like starch, sugar, wood, fibre, paper, are broken down and partially liquefied; the nitrogenous substances are liquefied, and the fats are partially decomposed. In this process, as in all processes of fermentation, gases are evolved and may be conducted off, and used as a fuel or an illuminant. This self-purification removes about 50 per cent of the putrescible substances in sewage, and its great practical value is that it reduces the amount of sand-area required for purification of sewage, increasing the capacity of an acre of sand-bed per day from 50,000 to 75,000 gallons to about five times as much.

Further, the septic-tank has made the English method of contact-beds possible. This method differs from intermittent filtration in that the sewage, instead of being applied slowly and allowed to drain through a bed of sand, is run rapidly into a water-tight bed filled with a coarse-grained material, as cinders, coke or broken stone, and retained in the bed for a given number of hours, after which the liquid is quickly run out of the bed. The action of a contact-bed depends on the presence of aërobic bacteria, which coats every individual piece of filling-material with a slimy growth. If, however, the bacteria slime increases beyond a certain point, the void spaces fill up, and the bed becomes spongy and will not allow the water to drain away. Can this growth of organisms be regulated, and is serious trouble to be apprehended from the deposition of the non-putrescible part or ash? These are the two points about which there is a great difference of opinion among English sanitary engineers.

My own opinion is that crude sewage cannot be successfully treated and should never be attempted, but that sewage, clarified by chemicals or by fermentation in the septic-tank, can be successfully purified. With such sewage the contact method offers to towns or cities where large areas of sand do not occur a process which, to be successful, requires merely the personal oversight of a well-trained sanitary chemist or engineer.

With the diversity of opinion regarding the practical success of the contact-bed, there has arisen a growing interest in the so-called continuous-filtration method. Continuous filtration is an attempt to still further increase the amount of sewage that can be treated on a given area, to treat 2,000,000 to 3,000,000 gallons in place of 500,000 gallons per acre per day. This method is based on the idea that if air is supplied to the filter at the same time that the sewage is being run upon the filter, and the filter is of such a construction and so drained that fresh air continuously remains in the filter, there is no necessity for periods of rest as required by the intermittent and contact-bed methods, as the only object of periods of rest in these methods is to supply sufficient air to the bacteria. Undoubtedly continuous filtration has certain merits, especially that of being able to treat larger quantities of clarified sewage on a given area than any other bacterial process; but even if it accomplishes all that is claimed, it is a process that requires a great deal of oversight and attention.

In conclusion, I would say regarding the various methods I have mentioned, that sewage-farming as a general method of sewage-treatment is not practicable; that chemical treatment only removes a part of the polluting substances in the sewage, and is advisable only in cases where sewage contains germicidal substances, thus preventing the use of the septic-tank; that intermittent filtration is the best of all methods for the treatment of sewage of cities where sand can be easily and cheaply obtained; that the septic-tank process is a most valuable adjunct and almost an essential part of all bacterial methods of sewage treatment; that the contact method is not adapted and should not be used for the treatment of crude sewage, but can be considered a very satisfactory method for the treatment of sewage after it has undergone putrefaction in the septic-tank; and that continuous filtration, though capable of treating much greater quantities of sewage per acre than can be done by any other method, is still in the experimental stage.

THE NEW TARIFF-RULINGS ON AMERICAN ART.

IT seems reasonably certain that the difficulties of the American artist over the admission into this country of work done while abroad are now at an end. On June 21 last the Treasury Department issued a document received at the New York Custom-house last Thursday, and defining the present position of Secretary Shaw on the puzzling question at issue. The substance of this document, which is based largely on recent decisions, is as follows:

Paragraph 703 of the Act of July 24, 1897, provides for the free entry of "works of art, the production of American artists residing temporarily abroad;" and the following rulings under said paragraphs are published for the information and guidance of all concerned, viz:—

1. The privilege accorded by paragraph 703 extends without limitation as to duration of residence abroad, provided, however, that the artists have not renounced or intended to renounce their American citizenship, but avow, in the manner prescribed by the regulations of the Secretary of the Treasury, their intentions of returning to the United States at some later period; and it is accordingly held that long periods of residence abroad, in one case of 27 years, of American artists are "temporary" within the meaning of said paragraph 703. Domicile consists of residence at a particular place, accompanied by an intention, either positive or presumptive, to remain there permanently or for an indefinite length of time. It embraces not only the fact of residence at a place, but the *animus manendi*, or intent to regard and make it the home. It is therefore held that the privilege of the free admission accorded by said provision of law to works of art of American artists residing temporarily abroad is extended to American artists without limitation as to duration of residence abroad upon the filing of the appended declaration:—

2. Children born abroad of citizens of the United States who have not renounced such citizenship are citizens of the United States by virtue of section 1993, Revised Statutes, and therefore entitled to the privileges accorded by paragraph 703.

3. A wife's political status follows that of her husband, and it is accordingly held that a woman by birth a citizen of the United States who has married a Canadian expatriates herself by the act of marriage; that she cannot be considered as residing temporarily abroad within the meaning of paragraph 703, Tariff Act of 1897, providing for the exemption from duty of "works of art, the production of American artists residing temporarily abroad"; and that the privilege accorded by such provision cannot be extended to works of art produced by her.

4. In the case of the importation of works of art of an American artist residing temporarily abroad, it is required that the work shall be positively identified as such production by the declaration of the artist, or of witnesses of such production, and such other evidence as may be required to establish the facts to the satisfaction of the Collector of Customs at the port of importation, and a consular certificate of identification or bond therefor is not necessary in such cases.

5. Works of art of an American artist are free of duty, notwithstanding the death of the artist and transfer of ownership of the works.

COMMUNICATIONS

[*The editors cannot pay attention to demands of correspondents who forget to give their names and addresses as guaranty of good faith; nor do they hold themselves responsible for opinions expressed by their correspondents.*]

"COLLAPSE OF THE STEEL-CONCRETE ELEVATOR AT DULUTH."

PHILADELPHIA, PA., July 2, 1902.

TO THE EDITORS OF THE AMERICAN ARCHITECT:—

Dear Sirs, — We would like to call your attention to an error in your editorial of June 7th on the "Collapse of the Steel-Concrete Elevator of the Peavey Grain Company, Duluth."

The statement is made by you that — "Assuming a pressure of 50 pounds per square inch near the bottom of the bin, there would be a lateral pressure of about 72 tons upon a ring 8 inches in height." This is true to the extent that the total pressure upon the ring *normal to its inner surface* would be about 72 tons, but it is not true that the whole of this pressure would be exerted to rupture the ring. Only the component of these forces, acting perpendicular to a diameter passed through any point where rupture may be supposed to occur, has to be considered, and the ring would, therefore, have to be strong enough to resist a tensile-stress of about 12 tons. A bar $4'' \times \frac{1}{2}''$ would seem to be ample, even allowing for the material removed at the joints.

We are not undertaking to defend in any way the design of the structure in question, but we do not want you to make the case out any worse than it is, as we are interested in "steel-concrete" construction in general, although we have no connection whatever with the Peavey Company or with the concern who did the work for them.

Yours truly, MERRITT & CO.,
JAS. L. MERRITT, *President.*

NOTES AND CLIPPINGS

STORAGE BATTERIES. — The storage battery is coming more and more into evidence, as its value in certain situations and the proper methods of handling it get to be better understood. It has suffered in the past more from external ignorance than from internal defects. Applied in many instances to meet conditions to which it was not adapted, usually overworked, nearly always uncared for, it has been the ugly duckling of the electrical art. Engineers generally know but little about it and its limitations. They frankly admit the fact, and seem to care little that it is so. Electro-chemistry is out of their sphere, they say, and battery mathematics are not intricate enough to attract the learned. The truth remains, however, that the storage battery is a good friend, and an ever-present help in the time of trouble, if it be properly laid out and installed, and does not suffer from persistent neglect. Altogether, there seems to be a growing demand for power batteries, and as their limitations and operation become better understood their performance will become more satisfactory and their dividend-paying possibilities greatly increased. The storage battery has an important place in industry, and with the exercise of proper care in its handling it will undoubtedly justify the claims of its exponents. — *N. Y. Evening Post.*

THE STRAIT OF CANSO BRIDGE. — The bridging of the Strait of Canso between Cape Breton and the mainland of Nova Scotia will be undertaken at once. The task involves great engineering difficulties, and an outlay of about $5,000,000. J. A. L. Waddell, of Kansas City, has been engaged to oversee the work. The bridge will be a cantilever, with a span of 1,800 feet, and will have a height of 58 feet clear above high-water. — *Exchange.*

THE WESTMINSTER PRESBYTERIAN CHURCH, BALTIMORE, MD. — One of the most historic spots of this city is the site of the old Westminster Presbyterian Church, which will celebrate its fiftieth anniversary, beginning next Sunday, with elaborate and appropriate exercises. This church was built in 1852 in the old Westminster graveyard at the corner of Fayette and Greene Streets, that site being selected in order that the church might protect the yard, in a way, and keep it in better condition, although the ground is held by the trustees of the First Presbyterian Church, corner of Madison Street and Park Avenue. The founders of Westminster Presbyterian Church were members of First Presbyterian, Franklin Street. The position and mechanical construction of the church are quite out of the ordinary. As the yard was well filled with graves and vaults, before the construction, pillars 7 feet high were erected between the mounds, and upon these pillars is the foundation of the church, leaving an open space beneath the church of ample height for visitors to stroll between the graves. For about fifty years John Spence, the gravedigger, and also sexton of the church, had a unique apartment in the corner of this lower space, where he lived alone with his large dog — a great Dane — which he called "Poe." The furniture of this room consisted largely of tombstones. His table was a vault about 4 feet high, while smaller stones served as chairs. In addition to these articles he had a couch on which he slept each night. Mr. Spence died a short time ago. — *Baltimore American.*

TRADE UNIONS IN GERMANY. — The fourth German Gewerkschaft (German Socialist Trade Union) congress, which met this week in Stuttgart, for several reasons is of interest. In the first place, for the first time in the history of Germany the German Government sent representatives to attend a Socialist labor congress. Legien, the able manager of the Gewerkschaften, in his greeting to the Government officials, said that they would realize that they were as well off at a labor congress as at a meeting of employers. He was glad that the Government had come so far as to extend recognition to the representatives of organized labor. It also deserves to be noted that, for the first time, English trade unionists were in attendance at a German trade-union congress, James O'Grady and Peter Curran having come from London to Germany for this purpose. The business report submitted to this year's meeting is also worthy of note, for it shows that the Gewerkschaften, in spite of the very serious economic conditions prevailing in Germany, have grown — in fact, since 1892 have tripled their membership, now having 481,798 members. The organizations last year had a total income of 294,189 marks, while their expenditures were 208,344 marks, exclusive of strike-funds, which amounted to 241,450 marks raised by special collection. The Gewerkschaften of Germany have had a slow, but sure, growth. While Lassalle and other early Socialist leaders were opposed to the trade-union idea, it is now admitted by the German Socialist party that trade unions are of great benefit to the laboring people. Strange to say, however, while Germany has over 6,000,000 workmen, only 700,000 belong to trade unions. This condition, therefore, was due to the fact that up to a recent date the coalition of workingmen was prohibited by the State, so that trade unionism had but little chance to develop. Since the Government has become more liberal trade unions have grown. — *Boston Herald.*

CONDITION OF NEW YORK UNION MEN IN 1902. — John McMackin, New York State Commissioner of Labor, has issued the following review of the conditions of labor in this State in the first quarter of 1902: The amount of idleness among the members of New York labor organizations was far smaller than it has been in the months of January, February and March in any recent year. Heretofore at least 10 per cent of trade unionists have been idle during those months, but this year the proportion has fallen to 6.2 per cent. The average number of days worked by the men increased from 58 in 1897 to a little less than 67 in 1901, and 67.3 in 1902. Average earnings of organized workingmen increased in about the same ratio, having been $155 in the first quarter of 1897, a little less than $183 in 1901, and a little over $184 in 1902. Building-operations in the first three months of the year, before the interruption occasioned by the usual spring disputes, were very active in all the large cities. The number of labor organizations in this State at the end of March was 1,930, which is an increase of 59 over the number existing last September. The number of new unions recorded was 152; of old unions dissolved, 93. The aggregate membership is now 279,930, an increase since September of only 3,809. The number of immigrants at the port of New York in January, February and March, 1902, was 104,937, which was 35,134 more than a year ago, and 76,829 more than in 1895. The Bureau of Mediation and Arbitration recorded 22 industrial disputes in the first quarter of this year, involving 75 firms of associations of employers. The number of employers directly affected by these disputes was 1,788, and the number indirectly affected, 744, while the duration of the disputes in working-days (time lost by the 2,532 workpeople) was 84,425. Four of the disputes that ended in the period began in 1901, while two of the eighteen disputes that began in the quarter are still unsettled. More than one-half the disputes turned upon the question of wages.

ARE THE PROFESSIONS COMMERCIALIZED? — The truth is, we hear too much about the commercialization of the professions. There are men who vulgarize them all — no doubt — and who sell their craft-right for a mess of millions, for there have always been such men. But there is another tendency of our time that is far stronger than the tendency to get wealth: it is the tendency to establish, to build, and to maintain institutions of any useful and honorable kind. Men give themselves in the most unselfish way to build up colleges and universities, hospitals, museums, clubs, associations, for the advancement of trades and professions, libraries — there is no end of the list. Men labor to turn their business into institutions. Many founders of great commercial houses work for their honorable perpetuity. Many manufacturers plan their factories so as to give them an institutional character and value. The naturally constructive tendency of an active people is towards institution-building. Strong men in almost every department of work show such a tendency, often as a dominant trait of character; and this is a stronger motive than the mere wish to be rich. The rich man who stands alone, who has not established something, who is not identified with some great institution, commercial or public, is not envied. He is more likely to be pitied. — *The World's Work.*

NOTES AND CLIPPINGS. 24

ONE of the most extraordinary accidents of recent years is the fall of the Campanile in Venice. This famous structure, more than three hundred feet high, the foundations of which were laid more than eleven hundred years ago, and which was completed in its present form nearly five hundred years ago, collapsed, almost without warning, in the middle of the forenoon of July 14, falling in a heap of ruins, but fortunately, without seriously damaging the splendid and famous buildings which surround it. According to the newspapers, the first indication of any movement in the tower was observed on the day previous to the catastrophe, when a crack was seen near the corner of the north wall, and two of the windows were found broken. The Government officials, who keep a close watch upon ancient buildings in Venice, at once arranged for examination and repairs; and, as a measure of precaution, the usual Sunday afternoon concert in the Piazza of St. Mark, under the shadow of the tower, was abandoned. If it had not been for this prudent proceeding, the loss of life might have been appalling; but the fall, which might very probably have been hastened by the movement of a crowd around it, was delayed until a time in the morning when the Piazza is comparatively unfrequented; so that there is reason to hope that the loss of life was inconsiderable.

THE Trustees of the Massachusetts Institute of Technology have decided to establish a course, very much in accordance with the plan suggested by Mr. Edward Atkinson, for the instruction of young men "in the selection and constructive use of materials with a view to minimizing the risk of destruction by fire." Our valued contemporary *Insurance Engineering* thinks that architects are remarkable for "an ungraceful verbosity," and a "characteristic loquacity," so that we hesitate to make any comments on this subject, but it might be remarked that, with the very best wishes for the success of the new course, and the highest opinion of its value to the community, we hope that the underwriters will not forget that it is to them that the graduates in the new course must look for employment after their graduation. Although, as *Insurance Engineering* informs us, "underwriters cannot afford to waste valuable time on architects," the latter have been able to learn, partly from the officials of the factory mutual companies, for whose work they have the highest respect and admiration, and partly from their own observation, at least as much of the science of fire-resisting construction as they find to be called for by their clients, and, while the graduates in the new course can be of great use to the public as inspectors, either for insurance-companies or official departments, they are not likely, we fear, to find their services in demand elsewhere.

AT the risk of giving further evidence of the "excessive volubility" which, as *Insurance Engineering* informs us, is one of the more conspicuous failings of architects, we will venture to suggest, in reply to Mr. Edward Atkinson's observation that opportunities for studying the effect of atmospheric corrosion on iron cased with masonry are difficult to obtain, that, in default of such opportunities, it is possible that valuable indications might be derived from investigating the action of hydrochloric-acid vapor upon cast-iron and steel protected by such a casing. The action of hydrochloric acid would be far more rapid than that of the carbonic or sulphurous acids of the atmosphere, but it would be affected, in something the same manner as the latter, by the action of the lime and cement in the masonry in intercepting and combining with the acid before it could reach the metal. In this way the advantage, or the reverse, of painting the iron, and the effect of leaving voids between the iron and the masonry, in place of grouting everything closely, could, at least, be studied by analogy, while waiting for a chance to make more decisive tests. We may say that, judging from our own observation, the theory that iron or steel embedded in masonry cannot rust needs to be accepted with reservations. It is well known that iron ties have been taken from buildings in Europe, after having been buried in masonry for seven hundred years, without a sign of corrosion, but there are also instances of the corrosion of iron similarly situated after the lapse of a few years. We have in mind a building, plastered outside with lime and cement on wire-lathing eight or ten years ago, the plaster on certain portions of which is already slightly, but uniformly, stained with the brown color of oxide of iron. The wire has never been exposed, on the front, to the direct influence of the weather, but it is possible that the back may not have been completely buried in the mortar; and it would be interesting to know whether the influence of the atmosphere, penetrating through the layer of mortar into the crevices behind it, has affected the wire, or whether there is something in or about the wire itself that has disposed it to rust, notwithstanding its alkaline covering, or whether the effect is due to some other cause.

A RATHER significant discussion took place not long ago at a meeting of a labor union connected with the Boston Navy Yard. There had been some talk of establishing a large number of holidays, about fifteen, for the special benefit of Government employés, and some of the speakers desired that the meeting should express its opinion in favor of the idea. To the astonishment and grief of the professional labor agitators, one of the union members rose to oppose any such action, on the ground that it was of no particular advantage to a workingman to have fifteen additional days to spend in idleness; and that, if the Navy Yard employés worked fewer days in the year than the men in outside shipbuilding establishments, the labor cost of the work that they did would be correspondingly increased, and the difference would tend to throw the building of ships of war into the hands of outside contractors, thereby depriving the Government mechanics of the work. This view, which certainly seems reasonable, was supported by a large number of men, in spite of the sneers of the "friends of labor," who fiercely denounced any man who could be so false to "union principles" as to refuse a chance to get paid for a day's work without doing anything. On the whole, the advocates of honest and faithful industry, even among workingmen, seem to have had the best of the argument, and their example should encourage other workingmen in rebellion against the "union principles" which threaten, in time, to destroy our industries as they have already dragged down those of Great Britain. It is interesting to note, in connection with this discussion among the Navy Yard workmen in Boston, that the construction of a large naval vessel which it was intended to carry out in Boston, has been, since the meeting, definitely assigned to another Navy Yard, in consequence, it is said, of the smaller expense of construction at the latter. Whether the difference in cost of construction was a matter of actual calculation, or whether it was inferred as probable, from the disposition shown by the union leaders, does not appear; but it is certain that people who publicly advocate measures for enabling workingmen to take the money of their employers without rendering any equivalent are, to say the least, very doubtful friends of labor.

PROFESSOR JOHN D. RUNKLE, long at the head of the department of mathematics in the Massachusetts Institute of Technology, and for some years President of the Institute, died a few days ago, at the age of seventy-eight.

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

Professor Runkle was a country boy, having been born and brought up in a village in New York State; but his capacity and energy made up for the disadvantages of distance from schools; and, although he was twenty-five years old when he finally secured his matriculation in the Lawrence Scientific School of Harvard University, he graduated three years later with both the Bachelor's and Master's degrees, and with a reputation as a mathematician which extended far beyond the University precincts. He was immediately engaged as one of the staff of the *Nautical Almanac*, and held this position for more than thirty years. While occupied in this work, he found time to edit the *Mathematical Monthly*, of which he was one of the originators, and his conduct of this brilliant scientific periodical added to his reputation. On the establishment of the Institute of Technology, in which he took an important part, he became a member of the faculty, and, with the exception of a few years absence abroad, his connection with the Institute was never afterwards interrupted. Personally, Professor Runkle was one of the most charming of men. He was universally beloved, by his pupils as well as by his associates, among whom he was conspicuous for his unwearied zeal in behalf of the Institute, and his wisdom and farsightedness in devising plans for making it more useful to the community.

THE improvements which are being made on the banks of the Charles River seem likely to effect, before many years, a great change in the distribution of the residence and business quarters of what is already virtually the central portion of the Boston metropolitan district. From what was locally known, in our college days, as the "ma'sh," a dismal bog, overflowed in high tides, which separated the river channel from the habitable portions of Cambridge, has been formed a beautiful park, extending along the shore, with varying width, for about ten miles. This parkway, or "Esplanade," as it is popularly called, facing south, and looking across the river to the city, closely resembles the "*quais*" of the new part of Geneva, and, like these *quais*, is sure, before long, to be lined with beautiful houses, hotels and club-houses, intimately connected by the West Boston, Harvard and Cottage Farm bridges with the business and residence sections of Boston, yet enjoying, like the palaces on the Geneva *quais*, the air and sunshine which are hardly to be had in the city. The Charles River Parkway has, however, the advantage over its Swiss prototype of being many times as long, so that it will afford, when complete, one of the most attractive of the magnificent drives characteristic of the park system of metropolitan Boston. At one point, the Esplanade parkway approaches very closely the main entrance to the grounds of Harvard University, and it is proposed by friends of the University to connect its enclosure with the Esplanade by a short, but wide, street, planted with trees, thus giving to the college grounds, what they have never had, an approach worthy of the beauty and interest centred in them. At present, the University precincts are reached mainly by Massachusetts Avenue, a street rather too narrow for the traffic through it, and encumbered with strings of electric-cars. Driving through Massachusetts Avenue is both disagreeable and dangerous; and the provision of a splendid parkway, short, and nearly straight, from the college enclosure, by way of the Esplanade and Cottage Farm bridge, to Commonwealth Avenue and the most fashionable residence quarter of Boston, would soon throw over the new route a large part of the traffic.

THE question of smoke-consumption has long agitated the city of Paris as well as cities in our own country; and although it is forbidden to discharge smoke into the Parisian atmosphere, just as it is into those of New York and Boston, the means for avoiding it is no better understood there than here. In 1894, a grand competition was held by the city of Paris for smoke-consuming apparatus. One hundred and ten devices were exhibited, of which not one was held by the judges to be satisfactory, and only six were awarded even a premium. Since then, very little progress has been made, and it seems to be an official, rather than a patentee, who has, so far, come nearest to success. This official, M. Sabourain, Inspector of the pneumatic-tube service of the Paris post-office, having several boilers under his charge, was led to study the possibility of diminishing, by some simple means, the discharge of smoke from their chimneys, a discharge which not only contravened the police-laws, but, to a certain extent, wasted coal. As every one knows, the principle of all smoke-consuming devices for boiler furnaces is to force the smoke from the fresh coal to pass through a mass of coal already brightly burning, so that the carbon of the smoke may be caught and consumed. Although the principle is simple, the practice is by no means equally so, for the carbon-bearing smoke, as it passes through the second fire, must find there oxygen with which to combine, and the problem of supplying oxygen both to the second fire and the smoke has been found a difficult one.

TO meet the case as directly as possible, M. Sabourain, taking, for example, the fire-box of a water-tube boiler, of the Babcock and Wilcox or Worthington type, inserts a fire-brick arch over the front half of the grate, above the fire-door, but curving downwards at the back, toward the grate; and, at the same time, an iron plate is hung in the ashpit, below the middle of the grate. When the fire is lighted, a quantity of coal is placed on the front of the grate, and, when thoroughly incandescent, the mass is pushed to the rear. The next charge of coal is put on the front of the grate, and the smoke which at first rises from it is directed by the firebrick arch down to, and over, the brightly burning coal beyond. At the same time, the plate, hanging loosely in the ashpit, cuts off some of the air from the rear portion of the fire, while it increases the proportion of oxygen which passes through the front part, and which the smoke carries with it to the rear, where the heat is sufficient to determine combination. This simple arrangement seems to have proved very successful. Although the firebrick arch, of course, cuts off the front part of the water-tubes from the direct action of the fire, the loss in evaporating power due to this is said to be fully made up by the more perfect combustion of the fuel, while the arch, by protecting the front ends of the tubes, and their connections, from violent fluctuations of heat, and from the currents of cold air which enter when the fire-doors are opened, favors constancy of pressure, and preserves the tubes and joints. On the first installation of the apparatus in a battery of boilers in the Avenue Bréteuil, while the smoke was practically suppressed, it was found that more coal was used, by about five per cent, than was burned without it. This difference was, however, discovered to be due to the loss of small particles of coal through the grate in shifting the charges from the front to the back of the fire; and, as *Le Génie Civil* tells us, it was substantially overcome by changing the grates, and putting in those of the Wagner pattern, the bars of which are only one-quarter of an inch apart.

EXCAVATIONS made on the site of the ancient Larissa, on the slopes of Mount Hermus, in Æolis, have brought to light some curious remains of Greek antiquity. The name of Larissa is common to many places in Asia, the Grecian mainland and Italy, and is believed to have been simply a word signifying a walled city in some language spoken long before the Aryan immigration. However that may be, the various Larissas are places of great antiquity, and some of them promise discoveries, perhaps rivalling in interest those made in Argolis and Crete. The Æolian Larissa, being favorably situated for settlement, according to ancient ideas, has been continuously inhabited for many centuries, with the result that each generation has done its best to pull down and remodel what the previous one left to it, and the relics of distant antiquity must be sought in the rubbish heaps of a less remote civilization. Investigation has, however, shown that the town, in the Hellenic period, was surrounded by strong walls, very probably left, like those existing at Chiusi and other Etruscan cities in Italy, by a race of which almost nothing is now known. Within the walls were spacious houses, with courtyards, and a temple built of terra-cotta, richly painted, apparently after the manner of the Asiatics. At the time of the Hellenic ascendancy, the inhabitants of the town, whether Hellenic colonists or indigenous to the soil, seem to have been taken with a fever of reconstruction, and the terra-cotta temple was pulled down, and the fragments broken up into small lumps, which were used to level up the streets; and by digging up the ancient streets small pieces of the terra-cotta have been recovered. Either at this time or earlier, two cisterns, each about twenty feet deep, were excavated in the rock within the fortifications to afford a reserve of water in case of siege. In demolishing the old terra-cotta temple the capitals of two columns, which afforded two large and heavy blocks, were reserved, and put as covers over the mouths of the cisterns, and here they have remained for something like twenty-five hundred years, until dug out for the enlightenment of hyperborean savages. The form of these capitals is very curious, and the comparison of their details with those of other prehistoric sculpture should cast some light on the early history of the region.

NOTES ON IRON AND STEEL CONSTRUCTION.[1] — IX.

NO other part of the structure of a modern building of the skeleton-construction type requires the exercise of so much care and study as the character and design of the foundations. The foundations cannot be designed or proportioned with that niceness that is requisite until the building has been partially designed, for upon the design of the building depend the dead loads which enter largely into the determination of the dimensions of the foundations and the footings. The foundations should be properly proportioned so that they will sustain with safety, and with a minimum, or at least uniform, settlement, the maximum load to which they are subjected. The loads upon the foundations consist of the dead and live loads, subject to exceptions and considerations as subsequently stated. The accumulated dead and live load should be considered, and the area of the footings or foundation-piers proportioned so that the greatest pressure per square foot of soil does not exceed the several values given for the various soils in the following table: —

Material.	Safe bearing-value in tons per square foot.
Compact bed-rock of granite	30
Compact bed-rock of limestone	25
Compact bed-rock of sandstone	18
Soft friable rock	5 to 10
Clay in thick beds absolutely dry	4
Clay in thick beds moderately dry	2
Soft clay	1
Dry, coarse gravel well packed and confined	6 to 8
Compact sand well cemented and confined	4
Clean dry sand in natural beds and confined	2 to 4
Good solid dry natural earth	4 to 6

Where there is liability of the foundation-soil being loosened by water, or by adjacent building-operations, due precautions must be taken to prevent serious results from attending such contingencies. Poor soils should, wherever practicable, be improved so that they are better adapted for the foundations. If the soil is wet, or saturated, an effort should be made to improve it by drainage; loose soils should be rammed or otherwise compacted, and piles driven at intervals to accomplish such results where required. All foundations should be protected against frost, which must be accomplished by excavating for the foundation at least 6 feet below the surface of the surrounding soil. Since foundations upon yielding material will settle, more or less, care must be exercised to see that this settlement be uniform, and in order to obtain uniform settlement the pressure on a unit of area must be the same in all foundations, footings and piers, providing the nature of the soil is the same throughout the area of the buildings. If the soil under different portions of the building is likely to have different values, it should be carefully tested and the several bearing-values ascertained at several points throughout the foundation-area, and the foundation-footings and pier-foundations so proportioned that the settlement be as uniform as possible. In testing foundation-soils it is usually necessary to make borings, in order to determine the different strata of earth that underlie the site, for only in this way can it be ascertained whether a seemingly secure foundation-soil is underlaid with quicksand; for if this is the case the designer usually endeavors to so arrange the footings that the stable strata will not be penetrated, and its bearing-value, consequently, partially, if not entirely, destroyed. One of the safest methods of testing is by building a test-pier, and loading it from time to time, ascertaining the settlement that takes place day by day. Instead of the test-pier sometimes a heavy square timber is used, which is provided at the top with a platform; this timber is set upon the soil on end, and, being properly guided, is loaded with some heavy material, such as pig-iron, the load being increased gradually, and the settlements that occur carefully observed. A square timber or a pier loaded in this manner does not give accurate results because it has four cutting-edges in a very small area, while the usual footing has but two cutting-edges, and a pier-footing, while having four cutting-edges, covers an area great in comparison. The results obtained, however, are on the side of safety.

Where the actual live load is variable, and seldom approaches the load originally assumed, as in office-buildings, equal settlement of the foundations must be obtained by proportioning the areas of the footings so that the dead loads produce equal pressure. For example, the heaviest loaded foundation-pier in a building supports a dead load of 200 tons, and a live load also of 200 tons, while another foundation supports a dead load of 150 tons, and a live load of 100 tons. The first pier sustains a total load of 400 tons, and assuming the soil to safely sustain a load of 4 tons per square foot of pier-area, the area of footing required for the heaviest pier to carry both the dead and live load equals 400 divided by 4, or 100 square feet. This area gives, when estimating on the dead load alone, a bearing-pressure of 2 tons per square foot. Using this unit bearing-value of 2 tons for the second pier, the area of base required, figured on the dead load alone would be 75 square feet, while if both the dead and live loads were considered in proportioning the foundation, the required bearing-area would have been 62.5 square feet, and the dead load would cause a pressure upon the soil under the second pier of only 1.6 tons, which would have a tendency to cause unequal settlement.

All foundation-piers resting upon soils of good dry natural earth, and having a safe bearing-value of from 3 to 4 tons per square foot, should be designed as shown in detail in the Figure 65. In this typical foundation-pier the concrete base should be composed of 1 part cement, 2 parts sand and 5 parts broken stone, the stones being small enough to pass through a 2-inch diameter ring; this concrete base should have such an area that the pressure per square foot upon the soil does not exceed its safe unit bearing-value. The offset of the concrete, as at *a*, should not be more than one-half the thickness of the concrete, while the thickness of the concrete marked *b* in the figure should not be less than 12 inches, and is not usually more than 18 inches. The body of the pier is best built of good

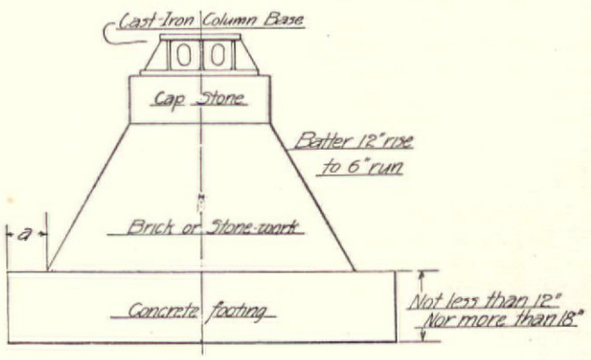

Fig. 65.

quality hard-burned, well-formed bricks, laid in Portland-cement mortar, and the area of the brick base should be so proportioned that the pressure upon each square inch of the concrete does not exceed 200 pounds; the batter upon which the sides of the brick pier is formed should not exceed a 6-inch offset to a 12-inch rise — that is, the rise should be in the ratio to the offset as 2 to 1, the sloping sides of the pier making approximately an angle of 60 degrees with the horizontal.

The area of the capstone upon the top of the brickwork should be such that the safe bearing-value of the brickwork is not exceeded, this value for brickwork in Portland-cement being usually assumed at 200 pounds per square inch. Should the load upon the stone cap be great, it is customary to use a heavy cast-iron pedestal, in order to distribute the pressure equally over the capstone. The area of the cast-iron base bearing upon the capstone should be such that the allowable crushing strength of the stone is not exceeded. The maximum working-pressure usually assumed for the materials employed in the construction of foundation-piers of the character just described and illustrated in Figure 65 is as follows: —

Granite	350 pounds per square inch.
Limestone	300 pounds per square inch.
Sandstone	250 pounds per square inch.
Brickwork in Portland-cement	200 pounds per square inch.
Concrete	200 pounds per square inch.

The capstones upon the top of such piers are usually of granite, limestone, or sandstone, and their minimum thickness is 12 inches, though their thickness in any case should never be less than one-fifth the greatest dimension if rectangular, and one-fourth the length of its side if square. The cast-iron pedestal upon the top of the capstone should be designed as described in a previous article. The following is an example of the application of the foregoing: —

[1] Continued from No. 1383, page 103.

Example. — It is required to design a square foundation-pier of hard-burned bricks, with concrete footing of Portland-cement mortar. The capstone is of granite, and supports a cast-iron pedestal, which in turn sustains a structural-steel plate and angle column. The load upon the column is 600,000 pounds, and the safe bearing-value of the soil has been ascertained to equal 3½ tons per square foot.

Solution. — The size of the cast-iron pedestal is dependent upon the unit allowable bearing-value of the capstone, taken from the preceding table as 350 pounds per square inch; then 600,000 pounds ÷ 350 = 1,714 square inches required, and the dimensions of the base will equal $\sqrt{1,714}$, or, approximately, 42 inches on a side. The size of the granite capstone will be determined by limiting its pressure on the brickwork to 200 pounds per square inch, and the area required on the bed of the stone will equal 600,000 ÷ 200 = 3,000 square inches, the length of its sides being $\sqrt{3,000}$, or 55 inches; its thickness will be one-fourth of its base, or 14 inches. The area required for the concrete-footing is equal to 600,000 ÷ 7,000, or 86 square feet, and, consequently, it should be 9 feet 3 inches square, its thickness being 18 inches. Since the sides of the brickwork are battered 1 to 2, and the dimensions of its top and bottom are known, its height will be found as follows: —

One-half difference between top and bottom dimensions = $\frac{(111-18)-55}{2} = 19$ inches; the 18 in the calculation is twice the offset of the concrete beyond the brickwork, which, as previously stated, should not be less than one-half the thickness of the concrete; it is, in this case, 9 inches. The batter being 1 to 2, the height of the brickwork should equal 19 × 2 = 38 inches. From these calculations the foundation pier, cap and pedestal, and the foot of the column can be designed as shown in Figure 66.

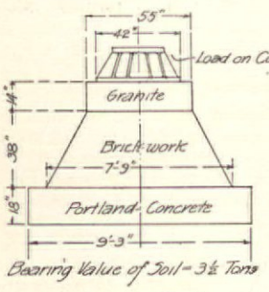

Fig. 66.

Where the weight of the building upon the foundations is great, and the soil offers insufficient bearing-capacity, pile foundations are usually resorted to; they are principally used, however, where the soil is of a clayey nature, underlaid with hard-pan or bed-rock. In such instances piles are driven to bed-rock, or to the hard-pan. Piles are of several kinds, and may be classed according to the material used, for they may be of timber, cast-iron or steel, and in some instances of steel castings filled with concrete. They may likewise be classed under two headings, determined by the processes by which they are placed. For instance, they may be driven by blows struck with a heavy weight falling some distance along vertical guides, or by a hammer worked by steam or gunpowder. Piles may be screwed into the ground, in which case they are provided usually with a cast-iron screw, having one turn, secured to the lower end, and the pile is made to penetrate the soil by turning. Piles are sometimes inserted in sand by the erosive action of a jet of water. In such instances a pipe is secured to their lower end, through which is forced a jet of water under pressure, which washes away the material beneath the end of the pile, the pile settling into the hole made in this manner, by its own weight. The piles used in building-construction are principally of timber, though where the new foundations are adjacent to others sustaining heavy loads, and where the soil is particularly susceptible to disturbance by jarring or vibration, screw piles are often resorted to.

Timber piles, if properly driven, and their location allows them to be submerged in water, are considered by conservative engineers as very satisfactory and permanent foundations. Foundation piles should not be spaced closer together than 2 feet from centre to centre, nor farther apart than 3 feet. Where their length is under 20 feet, they may be 10 inches in diameter at the large end, and 5 inches at the smaller, but where their length exceeds this dimension, they should be at least 15 inches in diameter at the large end, and not less than 10 inches at the smaller. All piles should be driven in a single foundation to an equal bearing, which should be determined by the distance the piles penetrate under the last blow of the hammer — that is, where they are not driven to bed-rock. The bearing-load on piles driven to bed-rock through stiff soil, capable of providing lateral support, should not exceed the safe direct compressive-strength of the timber taken at the least cross-section.

If the surrounding soil is plastic and incapable of furnishing lateral support, then the pile must be considered as a timber column, having the same length as the pile; its safe strength per square inch of mean cross-section shall then be determined by the following formula: —

$$W = S - \left(\frac{S\,L}{8.33\,D}\right)$$

in which formula W equals the safe load in pounds per square inch of section upon the pile; S, the allowable compressive-strength of the timber in pounds per square inch; L, the length of the pile in feet, and D, the mean diameter of the pile in inches. In this formula the allowable compressive values of the several kinds of timbers used as piles is as follows: —

White oak	800 pounds.
Southern long leaf, or Georgia yellow pine	700 pounds.
Cypress	800 pounds.
Chestnut	1,000 pounds.
Cedar	800 pounds.
Norway pine	800 pounds.
Oregon pine	1,200 pounds.

In locations where the bed-rock or hard-pan can not be reached, and the piles are driven through yielding material, their bearing-value may be ascertained by the following formula, which is known as the *Engineering News* formula, as it first appeared in that paper. In this formula the bearing-value, or

$$L = \frac{2\,W\,H}{p+1}$$

wherein W is the weight of the hammer in tons; H the drop of the hammer in feet, while p is the distance in inches penetrated by the pile under the last blow of the hammer. The penetration of the pile under the last blow of the hammer should, in applying this formula, only be considered when the burred splinters caused by the crushing at the top of the pile by the hammer have been removed.

There are many formulas for ascertaining the bearing-value of piles. Their results vary greatly, and many of them are not substantiated in practice. The following table is a statement of several of the principal formulas, though the one given above agrees more nearly than most of them with actual tests made upon piles, except possibly the one evolved from experiments by Hertiz: —

THE SEVERAL EMPIRICAL FORMULAS FOR DETERMINING THE BEARING-VALUE OF TIMBER PILES (DRIVEN BY HAMMER).

Authority.	Formulas.
Trautwine	$W = \frac{52\,P^2\sqrt{H}}{1+12p}$
Baker	$W = 100\,(\sqrt{P\,H} + (50\,p)^2 - 50\,p)$
Sander	$W_1 = \frac{P\,H}{8\,p}$
Hertiz	$W = \sqrt{500\,P\,H + (250\,p)^2} - 250\,p$

In these formulas W_1 = the safe bearing-value of the pile; W = ultimate bearing-value of the pile (both in tons); P = the weight of the hammer in tons; H = the drop of the hammer in feet; p = the penetration of the pile in feet under the last blow.

In driving piles for the foundation of important buildings test-piles should always be driven, so that their bearing-value can be approximately ascertained, and the results obtained by the formula to some extent checked. No fixed factor-of-safety can be employed for pile foundations, but in practice the factor-of-safety for driven piles ranges from 2 to 10.

If a pile depends for its bearing upon fractional resistance, it is probable that its strength will increase after driving, while, if it depends for its bearing-strength upon the bearing at its end, it will usually support a greater statical load than the load implied from the impact of the hammer in driving. After the piles are driven they are sawed off to a level, and may be capped either with granite blocks, concrete or timber grillage. When the capping is of timber or stone, then care must be exercised that the tops of the piles will all be cut off squarely and at one level, though where the piles are capped with concrete,

this consideration is not of so much importance. When piles are capped with a wood grillage, the grillage consists of heavy timbers about one foot square, made in the form of a stout frame, which is drift-bolted or pinned to the tops of the piles, the timbers in the grillage being likewise held together by drift-bolts. Upon the top of the grillage is placed heavy planking, upon which the masonry is started. The drift-bolt used in this construction is usually about 1 inch in diameter, and is driven into a ¾-inch auger hole; if the drift-bolt consists of a square bar 1 inch on a side, it is driven into a ⅞-inch hole. The timbers, in the top course, or layer, of the grillage, which support the planking upon which this masonry is started, are usually laid close together. Timber-grillage capping for piles should never be used unless it is entirely submerged. Concrete capping for pile foundations is, undoubtedly, the best construction for tall buildings. Where the masonry for the foundations is supported upon planking carried on timber grillage there is a danger of its slipping off, or sliding, and while this can be obviated by stepping the top of the grillage or by having drift-bolts project through the timbers and into the masonry, no such danger can possibly occur with a concrete capping, for the concrete is tamped in, around, and over the tops of the piles, as shown in Figure 67, and besides affording a durable footing which need not necessarily be under water, it has increased bearing-value, for to the resistance of the piles is added the bearing-value of the soil around them, upon which the concrete rests. In constructing pile foundations great care should be exercised to prevent disturbing adjacent buildings. If it is found necessary to drive them close to existing foundations, especially if such foundations support heavy buildings, and the surrounding earth is liable to considerable compression due to the superimposed load, such construction should be abandoned, and the foundations designed in such a manner as to prevent the danger attending the disturbance of adjacent footings.

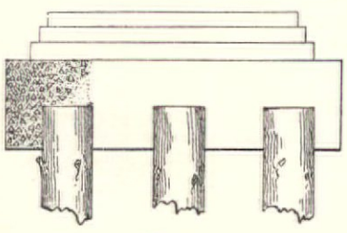

Fig. 67.

The next article will treat upon spread footings, a type of foundation that is particularly adaptable to high-building construction.

M. M. Sloan.

[To be continued.]

LIBRARIES IN THE UNITED STATES.[1]—I.

ALTHOUGH the library movement in America is by no means of recent growth, yet its developments during the last ten years have been so enormous that few buildings erected previous to 1885 would be found to-day suitable for modern requirements. The librarians themselves have settled points in the policy of the working of libraries which previously were undetermined, and it is the very active interest of these men which has so greatly assisted the architects to produce the very fine plans.

The remarkable generosity of Mr. Carnegie has helped forward the movement wonderfully. Last year alone he gave more than £2,500,000 for new buildings. The activity of other generous men and women has also been very great, as well as the public-spiritedness shown by many of the great towns in voting large sums of money for similar purposes. The result is that the American architect has an opportunity quite unequalled, and he decidedly is showing the greatest interest in the work. At present some of the recent plans seem as perfect as possible, yet the interest in the subject is so great and ideas in regard to the working of libraries are being so rapidly evolved that new developments are always taking place.

An endeavor has been made in this paper to select representative libraries in each class: many good ones, no doubt, have been missed — but during a short stay in so large a country that was inevitable — and many could have been included if space had allowed.

The descriptions of the various libraries have been grouped under the following heads (town libraries have been subdivided into three, according to the size of the library): (1) Reference libraries; (2) University libraries; (3) Town libraries (in three divisions); (4) Branch libraries; (5) Small libraries.

REFERENCE LIBRARIES.

It is difficult to distinguish between the very large town libraries, such as those of New York and Boston, and what might be called reference libraries proper. It is, of course, the lending-department which makes the distinction. Yet both the New York and Boston libraries will in the future become, as their collections increase, great reference libraries. These valuable collections will be studied on the spot, and it is from this point-of-view that the New York Public Library seems to have been planned. Its spacious reading-rooms, wonderful series of special libraries and exhibition galleries, are all designed for the student. Its description has therefore been included under this heading. The Congressional Library at Washington is decidedly the largest yet erected of this class. Its octagonal reading-room with the immense book-stacks projecting from three of its sides is the important feature, and it is interesting to compare it with the totally different method adopted at New York, where the main rectangular reading-room is placed over the seven floors of the stack-room. A similar plan to the latter has been suggested by the architects, Messrs. Shepley, Rutan and Coolidge, for the proposed John Crerar Reference Library at Chicago: here the reading-room, 240′ x 50′, is placed on the third floor, with four floors of stack below.

The Newbery Reference Library at Chicago can hardly be included as a recent one, yet it cannot be passed over without comment. It was the result of the ideas of the librarian, the late Dr. Poole. He held that a library should be really nothing more than a warehouse divided into rooms, in which the books were stored and read, and having no general reading-room or general stack-room, the books being shelved in the various rooms according to their subjects. The building has a frontage of 325 feet and a depth of 75 feet, and consists of basement and four floors. The plan is extremely economically arranged, and with the exception of the corridor at the back the whole of the floor-area is used for reading-rooms of various sizes, the end ones being each 50′ x 66′, the others between being smaller. Although Dr. Poole's plan was not wholly a success, yet its influence has been great, and the use of the special room with its special collection of books has become a law in library-planning.

Nearly all the States have reference libraries, but rarely have special buildings been erected. They are generally incorporated with, and form part of, the State House, as at Boston, Mass., and at Albany, N. Y. The recently erected one at Madison, Wis., is a distinct building, and is planned rather on the lines of a large town library. The main floor-plan is very well arranged.

THE CONGRESSIONAL LIBRARY, WASHINGTON.

The Library of Congress at Washington is by far the largest library-building[2] in the United States of America. It was in April, 1886, that Congress selected and acquired the site and proceeded to obtain plans. Finally, those prepared by Messrs. Smithmeyer and Pelz were adopted, but no limit of cost was fixed. By the summer of 1888 about one-half of the foundation-footings for the building were laid. During that year, however, Congress became dissatisfied with the progress that had been made, and lodged the entire control of the work, including the preparation of new plans, in the hands of General Casey, Chief of Engineers of the United States Army, with Mr. Bernard R. Green, C. E., as resident-engineer. In March, 1889, Congress enacted that the building should be erected at a total cost of £1,300,000, including previous expenditure, according to the plans prepared and submitted by General Casey, which were based on those adopted originally and provided a building of similar form, dimensions, and architecture. Under the new conditions operations were commenced in the spring of 1889 where they had been left off the year before, and the construction then proceeded without interruption until the building was finally completed in the spring of 1897.

The building is 470 feet in length by 340 feet in width, with four great inner courts. In height it consists of three floors above the ground; there is also a sub-basement. Each of the six pavilions contains an attic. The following is from Mr. Green's account of the building in the Smithsonian Report of 1898: "The first guiding principle of the design to accommodate a nation's library was that an ample general reading-room should be located within the mass of the books to ensure their easy reach and access. The next was ample light and air combined with security and latitude for future growth of the collections and their uses; then that all necessary accommodations should be provided for the constant work involved in the care, use, and increase of the library and its several departments. In endeavoring to meet all the utilitarian requirements of a national library in the present generation, it was found that library science was in a state of rapid evolution, and that the future of the subordinate departmental locations and needs was not sufficiently defined to enable special provisions to be made for them during the construction of the building. As a collection of books, however, to be housed in shelves and used by readers, the problem of shelving and reading-room was much more clearly presented, although book-shelving on a scale of millions of volumes had not hitherto approached a stage of perfection."

It was out of these conditions that the plan of the building was evolved. First, a reading-room of octagonal plan to accommodate 250 to 300 readers, amply lighted, is placed in the centre of the building. Adjoining this on three sides the great stacks of book-shelving are located, the main entrance to the room being on the fourth side. The four alternative octagonal sides face towards the large inner courts. The cross plan thus formed is enclosed by four fronts, the whole forming a rectangular plan and containing spaces for the subordinate departments of the library, for expansion of the stacks of book-shelving as future needs will require, and for the exhibition-halls, special reading-rooms, staff offices, etc. For the reason given the spaces in the front sections of the building were generally

[1] A paper by Sidney K. Greenslade [*A.*], Pugin student, Grissell Medallist, Godwin Bursar, read before the Royal Institute of British Architects, Monday, March 17, 1902, and printed in the *Journal* of the Society.

[2] See plan and interior views in the Paper on "Public Libraries," by the late Mr. J. M. Brydon, *Journal R. I. B. A.*, Vol. VI. (1898-99), pp. 214-15, 217.

not subdivided, but are so disposed as to admit of any desirable subdivision of a more or less permanent character that experience may dictate. At the same time the arrangements of windows, ventilation and communication, and the strength of the floors, are such that any part or the whole of any of the long halls may be conveniently occupied by shelved books, while the corner pavilion rooms are favorable for staff-work, reading-rooms, etc., and contain also lavatories and stairways.

The building has only two entrances — a two-storied one in front and a single one in the rear. The first is for the general use of the public and the other especially for the delivery and dispatch of freight. The front, or main, entrance opens into a great staircase-hall, 132 feet wide by 122 feet deep, extending the full height of the pavilion through the first and second stories. The great octagonal reading-room opens directly from the stair hall: it is 100 feet in diameter, 125 feet high to the crown of the dome, and is lighted by eight large semicircular clerestory windows, 32 feet wide, and the lantern above the dome. Small windows open into the alcoves in the four sides facing the courts. The seating capacity of the room is for 250. The space allowed each reader averages 4 feet of desk. The desks are arranged in concentric circles; there are three rows, the two outer rows have double desks, the readers facing each other. The double desks are 4 feet wide altogether, and are sloped 3 inches, the height being 2 feet 9 inches to the top; between them at the centre is a small screen 9 inches high. The space between the rows, centre to centre, is 11 feet 3 inches.

The card-catalogue and the superintendent's tribune and desks for his assistants are placed in an enclosed circular space, 29 feet in diameter, in the centre of the room. The floor of the superintendent's desk is raised 4 feet 8 inches above the floor of the reading-room and commands the greater portion of it. There is a small stairway of six steps up to it; balancing this stairway on the other side is one to the basement. At the back of the superintendent's desk is the cabinet containing the terminus of the system of book-carrying apparatus connecting the reading-room and stacks. The lift from the basement is also on this side of the enclosure. It is large enough to take the vertical book-trucks used in the room and stacks. This central desk is also in communication with the several stories of the book-stacks by means of pneumatic tubes for written messages and speaking. These are placed along the front of the superintendent's desk. There are twenty-four altogether — nine go to the north stack, nine to the south stack, and four to the east stack. Of the other two tubes, one goes to the librarian's room and the other connects with the Capitol. Each tube is numbered, and is worked by pressing a button, the action of which indicates also when the message is delivered at the other end. The height of the delivery-counter which surrounds this central enclosure is 4 feet 1 inch from the floor outside and 3 feet 4 inches from the raised floor inside. Its width is 2 feet 9 inches. The drawers for the card-catalogue for official use are placed on the inside towards the attendants. Outside the front is panelled only. The working-space for the attendants inside is 4 feet wide, and the space in front of the delivery-counter for the public is 7 feet wide. The card-catalogue for public use, book-shelves for dictionaries, encyclopædias, etc., with standing desks above as well as seats alongside, face towards this space.

The two tiers of alcoves on each of the eight sides of the rotunda call for special notice. Each bay, about 12 feet deep by 37 feet wide, is divided into three alcoves by book-stacks, and they are separated from the reading-room by bronze gates. These alcoves provide specially good places for quiet study. Above them is a gallery 35 feet above the floor of the reading-room, from which visitors not desiring to read may view without disturbing the readers.

The three great book-stacks project from three out of the eight sides of the reading-room and extend to the wings of the building. These are certainly most interesting and remarkable. All three are the same width, 45 feet, and the same height, 63 feet, but the lengths differ considerably — the north and south being 112 feet, against 30 feet for the east stack. They are absolutely fireproof, the only materials used being steel, iron, brick, glass and marble. The stacks are divided into nine floors, each floor being 7 feet high. The basement story is 14 feet below the level of the reading-room floor.

The fitting of the stack-rooms is quite independent of the walls. It consists of a slender rolled-steel framework of continuous columns and horizontal deck-members. These horizontal bars have proper anchorage in the surrounding walls — requisite for the lateral stability of the loaded stack. The decks are covered with white-marble slabs and contain narrow openings in front of the shelf-ranges for communication, admission of light, and the circulation of air. Between the stanchions a simple vertical cast-iron wing is attached, having the necessary teeth and lugs to receive the shelves and permit of their ready adjustment to any interval desired.

The shelf is of a gridiron form, being a set of parallel-bars of ∩ section. Its length is 3 feet 8 inches, in all the stacks; they are therefore interchangeable, and may all be removed from any bay or series of bays on a floor to make a passage-way. They are constructed of bars of rolled steel treated by the Bower-Barff process with a coating of magnetic oxide, which renders them as smooth as glass, and they are so spaced as to afford ample ventilation for the books and prevent any accumulation of dust. The central marble gangway, running from end to end of each stack-room, is 6 feet wide. The stacks are placed at 5 feet 4 inches centres, the marble passage-ways between them being 2 feet 6 inches wide — the 5-inch air-spaces on either side making the total width 3 feet 4 inches.

Each of the two large stacks has a shelving capacity of 800,000 volumes. The ultimate shelving capacity of the whole building will admit of the storage of over four million volumes. An elevator, stairway, and the endless-chain book-carrier are located in the middle of the stack.

The book-carrier is a pair of parallel endless chains running in a vertical shaft in the middle of the stack, thence in a horizontal duct in the cellar to a point below the central desk of the reading-room, where it turns upwards and ascends vertically to the delivery-outlet at the desk. A series of equidistant book-trays, eighteen in number, are suspended between the chains. The machine runs continuously, and automatically takes on and delivers books of the size of a quarto or less at its reading-room terminal and at each of the stack-stories. The speed of the carrier is about 100 feet per minute.

At the ends of each of the passage-ways between the stacks are arranged the windows. They are placed at the intersections of the decks, so that each may diffuse direct light into two tiers at once. In this way both the upper and lower portions of the stacks are well lighted. The glass-line at the sill is 2 feet 7½ inches above the floor of the deck, and between each sill and head, and 1 foot 7½ inches above the floor is placed a seat to each window for the use of readers or the attendants. The windows are fixed and air-tight, all air for warming and ventilation being passed up through the stack from the sub-basement by natural draughts or fans and discharged at the roof. The fresh air is taken into the sub-basement through openings looking into the courtyards, first, however, passing through a filter of cotton cloth to exclude all dust; after being warmed it ascends. If necessary, electric fans are used in case of any sluggishness in the natural current of air. Besides windows in the side walls, there are skylights in the roofs to each of the stack-wings.

From a point in the basement just below the centre of the reading-room, books of any size are transported in a few minutes to the Capitol, and returned by means of an underground endless cable, driven by an electric motor. The distance between the Capitol and the library is a quarter of a mile. A brick tunnel, 6 feet high and 4 feet wide, connects the two, and through this the endless cable moves. The speed at which the cable runs is 600 feet per minute. The four outer wings with their corner pavilions surrounding the great reading-room and stacks are divided and allotted as follows: —

In the basement a corridor 10 feet wide is placed next the inner courts, with a staircase in each of the four corners to the upper floors and sub-basement, in addition to the two flights of stairs at the main entrance. The sub-basement contains the electric machinery, workshops, copyright storage, etc. The basement contains two large binderies, one 130′ x 22′ 10″, printing-rooms, copyright department, library for the blind, staff lavatories under the alcoves of the reading-room, the superintendent's department, public lavatories, mail and packing rooms.

The first story is occupied on the right of the main entrance to the front by the Representative's reading-room, 105′ x 22′ 6″, and the Senator's reading-room, 48′ x 30′. The south wing contains the reading-room for current periodicals and newspapers: it is 217′ x 35′, with the delivery-counter and the attendant's desk placed at the entrance to the south stack. The order and catalogue rooms are in the east wing, each 130′ x 35′. The north wing, as well as the north-west pavilion, is fitted for maps and charts: the former is 217′ x 35′, and is connected with the north stack. To the right of the main entrance are placed the administrative offices, including the rooms of the librarian. It is proposed at this first-story level to connect the north and south stacks with the catalogue and order rooms by bridges across the courts.

On the second floor the rooms are chiefly devoted to exhibition purposes — prints, books, manuscripts, special collections and music.

The height of the basement is 14 feet, floor to floor; the first story 21 feet, and the upper story is 29 feet in the clear. The boiler, battery, steam-pumps, coal-vaults, ash-house, etc., are located under the east approach outside the building. There are sixteen 60-horse-power boilers and a coal-storage capacity of 3,000 tons. The steam operates the hydraulic pumps for elevator power and water-supply, the air-compressor for the pneumatic-tube system, and the dynamo-engines for electric-lighting and power apparatus, the exhaust from which is passed through eight sets of tubular tanks for heating the water required for warming the building. By the circulation of this hot water through cast-iron coils of 3-inch pipe, enclosed in chambers of brick distributed throughout the cellar, to which it is carried and returned by pipes, fresh air from outside the building is warmed and passed by natural draught up wall-flues to the respective stories and apartments above. The air thus taken into the building and circulated through the rooms is discharged at the roof through other wall-flues.

The great reading-room, the fine stack-rooms, and the ample accommodation provided for the work of the library and its future needs make this one of the most important libraries in the world.

[To be continued.]

DALLIN'S "MEDICINE MAN." — Cyrus E. Dallin's "Medicine Man," the life-sized figure of an Indian in gala attire, which received prizes at the Paris Exposition of 1900 and at Buffalo last summer, has been bought by the Fairmount Park Association of Philadelphia, and will be cast in bronze. Austria also made an offer for the statue, and in recognition of the compliment Mr. Dallin has volunteered a bronze replica, if Vienna will pay the cost of the casting.— *N. Y. Evening Post*

THE COLT MEMORIAL BUILDINGS, HARTFORD.

NEW YORK, N. Y.

TO THE EDITORS OF THE AMERICAN ARCHITECT: —

Dear Sirs, — Those of your readers who have had the pleasure of seeing, in Hartford, Conn., the church built by Mrs. Colt, in memory of her husband, and the adjoining parish-house, in memory of her son, have all doubtless carried away a general impression of artistic distinction. But, if asked for a specific characterization of that quality which to their apprehension dominates these works, or which, at all events, had most appealed to their sensitiveness, they would probably give quite different answers. What had most impressed myself, for instance, in the parish-house, was the notable result, perhaps unique in America, achieved by the architect's handling, in collocation with each other, of various species of stone, all contributing to an ensemble of color-harmony subdued in tint, as best befits most exterior building-surface, and highly effective and attractive to the artistic onlooker. One would, without surprise, find such an effect in some high-class textile fabric, but one would hardly expect it in a material so intractable as stone. Not, at all events, in this country of recent architectural creations, though in ancient edifices of the Old World, one occasionally meets similar examples, due partly to the genius of the designer, and partly to the blending touch of time, sun and weather.

I discovered, however, in confiding my impressions of this church and parish-house to their architect, Mr. Edward Tuckerman Potter, that, as regards the latter structure, he by no means acknowledged as its *piece de resistance* the color-scheme he had applied to its stone-work; with reference to both that and the church, his guiding principles, it seemed, had been based on quite another *motif*. As he proceeded to explain these, I found his remarks so interesting that it occurred to me they should not be confined to his listener of the moment, but would doubtless be equally appreciated by, and edifying for, a much wider audience. So, as our conversation on the subject approached its close, I asked him to give me, at his convenience, a memorandum of the chief points of what he had been telling me, which he did before long; and the more readily, perhaps, as the buildings in question had already been discussed in print in a manner meant to be, and which in fact is, largely appreciative, but to which their architect, at least on the point of "style," objected. Mr. Potter's observations, in treating of his methods, were, in substance, what appears in the earlier paragraphs and major portion of the following.

Yours truly, A. J. BLOOR.

In a work describing the Colt Memorial Buildings in Hartford, Conn., its author, after treating of one of them, the Church of the Good Shepherd, adds "in the same general style of architecture, that variety known as 'Early English.'" To this characterization the architect of the buildings, in his own copy of the volume, makes marginal reference in this note: "No, this is not an archaic reproduction, but live art; not 'Early English,' but the very latest development of Gothic treatment, and not more English than Lombardic."

In this architect's works the design is studied as from afar. The result is something to be looked at from a distance as well as at hand. The intention is to make it look, like some mountains, beautiful when seen from afar. The attainment of this end depends on the outline, and mainly the skyline, which, again, depends on the construction, or what can be erected on the plan, and so primarily on the plan.

When the plan alike suits both possibilities for good outline to be erected on it, and satisfactory provision for the uses indicated is secured, the great primal work of the designer — the design — is virtually complete. Next, it is important that as one approaches the building, it should continue to interest and please, as mountains do when we approach them and perceive how they are divided into ridges, ravines, etc. Next, when we are yet nearer, we want continued beauty; the fine trees, their foliage, their blossoms, even their last details may be compared with the details of a building, the *oggetti* — the objects — many of them more of a literary than of a strictly architectural character — that add interest to them, because, like types or subjects of carving, of their appropriateness to that particular building. These last naturally take and absorb the attention of the mass of visitors to a building, to the neglect of appreciation of its plan, its construction, its outline, its design. They interfere with a due conception of what has been involved in the sense of the drawing or form of its various parts, its elevations, exterior and interior, of the divisions of each, of the mastery in choice and selection, and of the art, the knowledge, the taste, the sensitiveness to effect embodied in all of these.

These general forms and details constitute what makes the character of the building — the style of its architecture; and the natural seeking of some word which will at once express this style, without the circumlocution of further description, without the trouble of analysis and study of that style, leads to words that misrepresent it. Gothic is a generic term, but the same so-called Gothic building has been sometimes classified, by persons who claimed to be fitted to instruct others, as Early English, Italian, Lombardic, and Victorian, when none of these words are really applicable in any justly descriptive sense.[1] True, what is built during the reign of Victoria is in that sense Victorian, but this applies to buildings widely different in style. The use of a color-scheme to add to the architectural effect of a building is quite usual in pseudo-Italian-Gothic, but color, *per se*, scarcely constitutes a style. The form of voussoirs of arches in which the extrados and intrados are not concentric is a feature of much Lombardo-Gothic work, but one such feature does not constitute, though it may be one mark of, a style. Narrow lancet-windows are common in Early English, but are not confined to the Early English style.

If we analyze the style of this architect's buildings we shall find that they always arise out of, and are governed by, the construction. The general forms are plain. The angles of jambs are generally chamfered. Mouldings are rarely used. The style might be described as "chamfered" to distinguish it from styles described or differentiated by the forms of their mouldings.[2] Stones of more than one color are used, and chiefly in the arches; the extrados and intrados of arches are rarely concentric. What governs the line of these arches it is difficult to determine. The joints that separate their voussoirs do not all radiate from the same point. We are led to the conviction from a study of these arches and their voussoirs that this fad gives them a peculiar variety. "The arch never sleeps," it is said; and not only is it so in these arches — as in all arches in fact — but there is something unsleeping, and so possibly morally uplifting, in their lines, something that stimulates in the sensitive nature a sort of

[1] From the strict constructional point-of-view it can hardly be admitted that there is any such style as Italian Gothic.

[2] Chamfering is largely used in the most ordinary wooden houses for the finish of piazza-posts, door and window trim, and at arrises generally. The word seems to have neither sufficient distinctiveness nor distinction to be fittingly applied, as descriptive of style, to structures of the rank of the Colt Memorial buildings.

emotion, a drawing in of the breath even.[1] A sensitive woman has testified that the sight of some of this architecture has each time moved her to tears. "I have that feeling that they call a frog in the throat," said another. "Many have said that they have that feeling here," was replied by one interested in the building. The treatment of even such a subordinate feature as a chimney may give such a sensation. Indeed it is common experience that all forms affect the sensitive nature through the eye, and not alone those finer ones appealing to us in pictures or in nature. We experience this in the reverse when we feel depressed by some low-browed or otherwise displeasing or prosaic or ugly buildings. In such a case we hear it said: "It oppresses me." "I could never live there." "I never want to see it again." "It is frightful to see." To analyze and find and select consciously what will produce such a semi-physical effect on the sensorium, and so give pleasure or pain by an architectural design, is art. To arrive at and effect such results without such analysis and conscious selection, but by merely unconscious feeling and choice, is genius.

Dismissing questions of *motif* and "style," Mr. Potter said further: "The burning in the great fire at Chicago of a church designed and built by myself led me to seek to make incombustible Gothic structures, when later called upon to design other churches. The first of these is the Church of the Holy Innocents, the Stevens Memorial Church, in Hoboken, N. J. Owing to the fact that no such building existed, I had to depend on the word of the constructor of the iron roof as to its qualities for the non-conducting of heat and cold; so I omitted making an air-chamber in the roof between the inside plastering and the outside slating; and the church has in consequence been very difficult to heat in winter and is, perhaps, very hot in summer. In the Colt Memorial Buildings this experience is profited by, and an air-chamber, of the thickness and depth of the rafters, being formed between the inside plastering and outside slating, no complaints of cold or heat have reached me."

Noticeable in the ironwork is the use of lattice-girders that have the effect of clerestories; and, by this means inside columns, to carry a wide and heavy roof, are avoided. The frankness of using the simple forms of these girders, and merely filling them with glass, is to be noted. It is by such expedients as these that the cost of the building is kept within bounds; a cost which would have been greatly surpassed by a Renaissance building of the same size and accommodations. The front elevation of the parish-house, with its staircases along the side, and the *ringhiera* in the centre, shows a novel combination, though a *ringhiera* on a public building is a not unusual Italian feature.

Had the piers of the balustrade crowning the arcade which is carried along above this staircase been finished with statues, as originally intended by the architect, the Italian character of the arcade would have been more marked.[2] The end elevations call for commendation as successful examples of rigorous symmetrical outline. This is best seen at some distance from them and exactly opposite their centres. The rear elevation, gaining a central feature from the tribune, which is such an important adjunct of the main room in the building, is in interesting contrast to the front elevation of the structure. The finish of the whole exterior mass, from groundline to delicate spirelet and from wherever seen, is noticeable.

If now we give consideration to divisions of the design, the interior façade which frames the tribune is especially noticeable. There is a sense of grandeur in this special rendering of the architect's concept which is remarkable, when we consider its measurements, and how low is the height of the openings to the tribune. The details of this tribune, both without and within, well repay prolonged study. Another piece of design especially to be noted is the exquisite arcade that looks into the staircase. Not only its interesting carving but its elementary lines call for commendation. It is a beautiful work. The elevations of the interior ends, with their great arches, — arches made more interesting by the little doorways above them, that give access to the bridge which leads to the spirelet, — are carefully studied, and of noble proportions. The juxtaposition of grand leading forms with delicate details throughout the Colt Memorial Buildings is well worthy of attention, and is to be remarked in much of the architect's other work in various places; notably in St. John's Church, Yonkers, N. Y.

Design, in the sense of selection and judgment, as differentiated from ornament and unrelated details, is shown in the solidity of effect given to the parish-house by the exterior treatment of the staircases at the angles of the building; the windows being mere narrow slits without decorative form, finish or color.

[1] This saying that "the arch never sleeps" originated with the Arabs, doubtless owing to their experience with the Moorish Arch, which they have so much employed. It may be admissible, from the layman's merely sentimental point-of-view, to assign credit to the arch for its sleeplessness, but that the arch never ceases, more or less, to jeapordize its imposts, and, consequently, the whole wall in which it occurs, has always hitherto been considered its vice; and the architect takes a bold stand, and one apparently at issue with his professional obligations in his practice, who cites the fact as a virtue. For the first requisite demanded of the mass of a building is stability, and the upholders of that mass, the arch no less than the column with its architrave, should be inviolable by any coördinate stress or strain. Nearly all Europe's Gothic work of the mediæval era, comparatively near as that epoch is to our own, is tied up with iron to reinforce its original construction, whereas the trabeated temples of Greece and Egypt, thousands of years older, stand to-day, when untouched by earthquake or the destroying hand of warfaring or stone-quarrying man, as intact as when erected.

[2] Statues of "Fortitude," "Truth," "Friendship," "Fidelity" and "Magnanimity."

NOTES AND CLIPPINGS

First Steps in the Philippines. — When the Filipino sets out to build a house there is one thing that he never omits, that is, to erect the apparatus by means of which all his children will learn to walk. This is done by cutting a hole in the floor of his high and dry dwelling, through which he passes a long hardwood pole, sharpened at one end, which he drives in the ground below, until the part in the house stands about 19 or 20 inches above the floor. He then makes that part of the hardwood pole in the house firm and solid by driving wedges into the interstices formed by the passage of the stake through the split-bamboo floor, and, when all this is done, his next care is to secure a section of bamboo about half a foot longer than the length of the hardwood stake from its top to where it enters the floor and double the circumference of the latter. This section of bamboo is, of course, hollow, and fits over the hardwood stake like a glove. The apparatus is now about finished, and lacks only two things in order to be ready for business. This Mr. Filipino soon attends to. First he bores a hole through the two opposite walls of the bamboo sheath, at the top, where it extends upward about half a foot taller than the stake, and into these two holes he inserts a long hardwood handle which extends at right angles to the upright stake and bamboo case, thus completing the apparatus for teaching children to walk. The manner in which this curious arrangement is operated is very simple. When the mother of a family thinks that it is time for one of her youngsters to learn to walk she simply places the child on its feet, and with its hands grasping the bar, or handle, of wood extending out from the bamboo cylinder. Sometimes the child is tied by the waist to the handle, which the youngster grasps with that peculiar firmness characteristic of all children and especially those of savage tribes, and which, the evolutionists say, is a legacy from our simian forefathers, who lived in trees and who were obliged to hold fast and firm to the limbs or fall. And the minute that baby Tagalo does so the pressure of his body on the handle starts the bamboo cylinder to revolving around the hardwood core, so that baby, fearing lest he fall, clings to the rod with grim perseverance, squalling for his mother and trying hard to support himself by the handle, which continues slowly moving off and away from him. Thus, in an endeavor to keep from falling, and at the same time to keep pace with the slowly revolving cylinder, the child learns in a short time to walk. — *Washington Post.*

Permeable Walls. — Every one knows that air passes through the walls and ceilings of a closed room, and as long ago as 1878 it was proved that the rate of penetration depended mainly upon the excess of temperature of the inside air over that of the outside air. With walls of ordinary thickness it was observed that about one twenty-fifth of the atmospheric contents of a room would be changed for every degree Fahr. difference per hour. Thus, if the outer air were at 35° Fahr., and the air in the room at 60° Fahr., the latter would be completely changed in the space of one hour by transpiration through the walls. More recent inquiry seems to show that in the case of papered walls, it would not be safe to assume that much more than one-eightieth of the air will be changed per degree Fahr. per hour. Further, it is the fact that walls covered with paper containing oil varnish or a coating of paint offer considerable resistance to the passage of air. As very little provision is designedly made for ventilation in ordinary dwelling-houses, and especially in those at low rentals, the subject to which we now allude may well be considered by architects. The employment of reasonably porous building materials is clearly calculated to exercise a beneficial influence upon the atmospheric conditions of a dwelling-house or other building. — *The Builder.*

Berlin Elevated-railway Structures. — The Paris *Bulletin des Arts* praises the appearance of the new Berlin elevated electric road as an ornament to the city and a triumph for the architects. The ironwork is said to be really graceful in effect, while the stations are models of sightliness and convenience: all of which is, according to the *Bulletin*, in strong contrast with the Paris underground-road stations, which are condemned as insults to the public. The secret of the Berlin success is said to lie in the fact that first-class architects were invited by the Government to furnish designs for the work, and the best were chosen by a committee consisting of artists, architects and engineers. — *N. Y. Evening Post.*

Proposed Monument to Prison-ship Martyrs. — A joint resolution appropriating $100,000 for a monument to prison-ship martyrs to be erected at Fort Greene, Brooklyn, N. Y., was passed by the Senate June 27. It provides that the appropriation of $100,000 shall be made, on condition that an additional $100,000 shall be raised, the work to be done under direction of the Secretary of War, the Governor of New York, and the Mayor of New York City. — *Exchange.*

Originality. — The architects who have the alteration of the White House under way have been taking photographs by way of suggestion, in New York's City-hall, which architects are said to think is as nearly architecturally perfect as any building in the United States. But why not be original? — *Exchange.*

[If originality is the one thing to be sought, let the asker of the above question wear his shoes on his head in place of his hat. — Eds.]

NOTES AND CLIPPINGS. 32

ARCHITECTS will be anxious to learn the result of expert investigation of the causes which led to the fall of the Campanile in Venice. The newspapers seem to assume that the pile foundations gave way, either as a result of dredging in the Grand Canal, or, as one authority has suggested, through the effect of an earthquake. While an earthquake might possibly open a rift in the ground under the ends of the piles, and let them suddenly down, it is improbable that this would occur without the shock being felt to a certain extent in the neighboring soil; and the theory that the catastrophe was due to the undermining of the soil by dredging is also open to objections. Although we are gravely informed by one newspaper that "there are people who are saying that the subsoil of the city has deteriorated, and that the piles and pillars on which the buildings of Venice rest are rotting away," it is hardly necessary to point out that the "rotting away" of the "piles and pillars" of Venice is a phenomenon very little to be feared. A few years ago, some German engineers had occasion to remove the pile foundations of a bridge constructed by Julius Cæsar, about a thousand years before the Venetian Campanile was thought of, and the piles, after an immersion of nearly two thousand years, were found perfectly sound. It will be remembered, also, that the piles on which the lake-dwellings of Switzerland were built are still sound, after the lapse, probably, of at least five thousand years, and, perhaps, of a much longer period; so that, whatever may have been the matter with the foundation of the Campanile, it is very unlikely that the piles under it have "rotted away," or that those under any other of the ancient buildings are in danger of doing so, whether in consequence of "the deterioration of the subsoil," or for any other reason. If, on the other hand, the ground under the ends of the piles has given way, it is strange that the collapse of the tower should have been so sudden. Every architect who has practised in Boston or Chicago, or who has observed the old houses in Amsterdam, knows the effect of the yielding of the ground under a pile foundation. Far from collapsing suddenly, and letting the building over it come down with a crash, a subsoil overloaded in this way yields very slowly, for the obvious reason that the overloaded portions, pressed outward, must force their way gradually into the surrounding mass, whose inertia is increased by the weight of the water above it. In most cases years, and often centuries, pass before the effect becomes very noticeable, and, as the resistance of the subsoil is, practically, never uniform, the movement almost invariably takes the form of an inclination toward the softer part of the ground, which, at first hardly perceptible, increases very slowly.

IN the case of the Campanile, nothing of this kind seems to have occurred. The tower was practically vertical, and had remained so for a thousand years; and that the supporting earth should be so completely removed from under it in a few hours as to cause its total collapse, without any warning settlement, is hardly credible. Moreover, unless the failure of the subsoil took place uniformly over the entire surface of the ground covered by the piles, which is hardly possible, the tower would have sunk toward one side, and have fallen at length, instead of breaking down in a heap. Although it is hazardous to make guesses in regard to an occurrence at such a distance, it seems possible that the cause of the trouble might be found in the construction of the tower itself. Every one is familiar with the inclined plane, paved with brick, and supported by brick arches, which extended from the bottom nearly to the top of the tower, making some thirty-five turns. It is obvious that, in such a construction, the thrusts of the arches would, to a certain extent, accumulate from the top to the bottom, and, if the abutment should at any point be insufficient, the slightest yielding, by allowing the arch to flatten, would greatly increase the lateral pressure, at the same time that the abutment became less capable of resisting it. Most arched structures fail suddenly in this way, the first yielding of the abutment producing an increase of the thrust which carries everything before it. In the case of the Campanile, it is known that the walls were in bad condition, and they do not seem to have been improved by the cutting of a hole in the lower portion for the insertion of an iron beam, a proceeding which, as the newspapers inform us, caused the brickwork over the opening to "descend several inches"; and, the disintegration of the walls having once begun, the internal forces, no longer adequately restrained, would be sufficient to bring down the whole mass.

THERE is something rather unpleasantly suggestive of Italian astuteness in the discussion which is going on in regard to the reconstruction of the Venetian Campanile. Offers of pecuniary assistance have been received from all over the world, and the amount of the subscriptions promised for the purpose is said to be something like half a million dollars. Meanwhile, as the newspapers inform us, the Venetian authorities seem to look on gloomily, and make estimates of the cost of rebuilding the structure, which, it is given out, will be twelve hundred thousand dollars. As the tower was forty-two feet square, outside, and three hundred and twenty-five feet high, to the top of the decorations which crowned its pyramidal roof, a simple calculation will show that this enormous sum would give nearly three dollars a cubic foot for rebuilding a very simple brick structure, almost perfectly bare inside, out of materials which lie scattered over the site, the bronze doors, and a large part of the marble decoration, being uninjured, and ready to be put back in their places.

THE New York *Evening Post* speaks plainly and decidedly to the effect that appropriations of public money by Congress in aid of local "Expositions" should cease. Before adjourning, the last Congress appropriated more than six million dollars in aid of the St. Louis exhibition of 1904, and, if the affair should prove financially unfortunate, there is no certainty that appeals may not be made for still more money, as was the case with the Charleston Exposition, the gates of which were not even closed before its managers made an urgent demand upon the Government of the United States to make good the deficit in their accounts. If any such exhibition deserved to be helped in this way, it would be that at Charleston, where the people of a small city, nearly ruined by the concentration upon it of the destructive forces of the Civil War, made a brave and noble effort to claim again their place in the current of American life; yet the rejection of the petition by Congress was approved by most sensible people. The fact is that, as the *Evening Post* says, and as nearly all the most intelligent journals in the world have been saying for two years, every one is tired of great exhibitions. Even the Paris Exposition of 1900, although it enjoyed the great advantage of being held in a city which, alone, is a perpetual attraction to

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

all civilized people, was financially a failure, at the same time that, by its wearisome extent, it did much to disgust people with great exhibitions in general. One of the most interesting portions of the Paris Exposition was the annex at Vincennes, where not only the cattle and farming appliances, but the balloons and automobiles were shown; yet there were practically no paid admissions to the annex, the visitors to the main exhibition, although the charms of the annex were described in posters which were everywhere spread before their eyes, finding themselves too much fatigued, in mind and body, to take the short trip to Vincennes. The St. Louis Exposition, almost necessarily, is planned on a larger scale than any which have preceded it, in order to give room for the constantly increasing variety of exhibits which will seek a place in it; and, earnestly as we wish that the fair, and the very interesting things which will be shown there, may be properly appreciated, it seems too much to hope that a sufficiently large number of people will brave the weariness of sightseeing in the midsummer climate of St. Louis to make it so successful, financially and otherwise, as it will, undoubtedly, deserve to be. Except for Government assistance, this would probably be the last general exhibition in America for a generation, at least; but there is danger that professional promoters, hoping to divert a portion of the public millions into their own pockets, will continue, on various pretexts, to apply to Congress for assistance in such affairs, to the injury of the public; and we hope that it may be made known to these speculators that no more appropriations of the people's money for such purposes can be hoped for.

MR. BRUCE PRICE makes an excellent suggestion in support of the proposed amendment to the Building Code of New York, requiring woodwork in high buildings to be covered with metal. At present, the law requires woodwork in such buildings to be of fireproofed wood; but, as Mr. Price well says, architects have a certain distrust of fireproofed wood, the laboratory tests of which do not give very convincing indications of its behavior in a conflagration, while the various fireproofing processes are believed in the profession to injure, at least in some cases, qualities in the timber which are desirable. On the contrary, the covering of woodwork, particularly of doors, sashes and mouldings, with sheet metal has been practised for many years, with a success which is known to all architects; and there are very few of the latter who, if called upon to choose between metal-covered wood and timber treated by any process now in common use as a fire-resisting material, would not prefer the former.

SOME time ago, in the discussion upon the best method of relieving the congestion upon the Brooklyn Bridge, it was proposed to equip it with a moving sidewalk, like those which formed the delight of children at the Chicago and the Paris Expositions. The idea was favored by the engineer to the Rapid Transit Commission, and by Mr. Lindenthal, the Commissioner of Bridges, and it is now announced that a company is ready to undertake the construction of such a sidewalk, as soon as the necessary concession can be arranged. The plan already worked out contemplates a main platform, moving at the rate of ten miles an hour, approached by three others, moving at rates intermediate between this and absolute rest. In this way the transition between the stationary platforms and those moving at the greatest speed would be so gradual as to obviate all danger. In Paris, there was only one platform moving at a speed intermediate between that of the main platform and perfect rest, and more than nine million passengers are said to have been transported without a single accident. Whether the dense crowd which covers the sidewalks of the Brooklyn Bridge in the morning and evening could be transported with equal safety is, of course, undecided, but there seems to be no serious reason for doubting it. We watched many times the operation of the Paris "Plateforme Mobile," and, although we often saw people lose their balance, and fall, in stepping from one platform to another, they were not hurt, for the simple reason that the worst that could happen to them was to be rolled off the more rapidly moving platform to the other. Being guarded by railings, they could fall no farther than to the platform; there were no crevices in which their feet or hands could be crushed; and the most distressing mishaps were those in which small children, accompanied by their papas, or mammas, or big brothers or sisters, failing to step in unison with them from one platform to another, found their guardians carried mysteriously away from them until the latter could jump back again and return to their charges.

THE insurance-companies are studying the question whether a policy-holder can store a naphtha-burning automobile, or motor bicycle or tricycle, in the insured premises without vitiating his policy; and the answer to the question will interest a great many people. Few persons know how dangerous naphtha vapor is. According to one authority, if half a cupful of ordinary gasoline is thrown around the floor of a room of average size, and allowed to evaporate, and a lighted match is then thrust from the outside through the keyhole, an explosion will take place which will blow the windows out; and the same authority mentions an accident which occurred in Philadelphia, where a man in an upper story was cleansing a sofa with gasoline. The vapor of the gasoline descended the stairs, and reached a light sixty feet away. Instantly there was an explosion which blew out the rear wall of the house. It is not surprising that underwriters view with disapproval the storing of machines containing tanks of gasoline, held in, very frequently, by leaky valves, in rooms containing valuable property; and, while policy-holders who use automobiles will do well to study what their contract already says in regard to explosive fluids, it is likely that insurance boards will, before long, adopt some definite rules on the subject.

SEVERAL of the daily papers mention the alleged discovery of "an alloy of nickel and steel" which does not expand with heat, and they inform their readers that this alloy would be an excellent material for boiler-tubes, "whose varying length tends to impair their connections and create leaks." It is extremely unlikely that anybody has discovered an alloy of nickel and steel, or any other substance, or mixture of substances, which will not expand with heat; but, in case any one should discover such an alloy, it might be well to observe that it would be about the most unsuitable material for boiler-tubes that could possibly be used. As boiler-tubes are firmly fixed at each end into the heads of the boiler, it is obvious that every time that a boiler fitted with such tubes was heated, and the steel or iron shell thereby expanded, the inexpansible tubes would all be pulled out of their connections. It is true that boiler-tubes often leak, but this is due to insufficient, rather than excessive expansion, and the perfect boiler would be one in which all the tubes expanded at precisely the same rate as the steel shell, and were always kept at exactly the same temperature with the shell, so as to avoid the currents of cold air, and irregular firing, which cause leakage at the connections of ordinary tubes.

ONE member, at least, of the new administration in New York has earned the gratitude of his fellow-citizens by converting what has hitherto been a source of expense into a means of profit for the municipality. This official is Commissioner Woodbury of the Street Cleaning Department. Major Woodbury is, apparently, acquainted with the maxim that "dirt is matter in the wrong place," and has used his powers to redeem some of the dirt which New York gets rid of at such great cost, and put it into a position to be of value. In pursuance of this idea, he began, some time ago, to visit the various police-stations, and instruct the patrolmen in regard to the directions which they should give to housekeepers for separating ashes and garbage, which in New York, as in other civilized cities, are now required to be collected separately. The result of this sensible proceeding has been that ashes are collected from the houses almost clean, and, instead of having to be carried out to sea, they are available for any purpose to which inert mineral substances are adapted. In these days of "cinder concrete," there is a great demand for substances of this sort, which can be used, mixed with cement, for fireproof filling, and the Roebling Construction Company, finding the ashes, under the new system, clean enough to be so used, bought five hundred cubic yards, at eight cents a yard. As the cost of conveying this quantity out to sea would be sixty-five dollars, the net profit to the municipality in the transaction was one hundred and five dollars. As the quantity of mixed ashes and garbage sent out to sea before the inauguration of the new system amounted, on an average, to about seventy-five hundred cubic yards per day, the profit to the city, if it could all be disposed of in this way, would be nearly six hundred thousand dollars a year.

LIBRARIES IN THE UNITED STATES.[1]—II.

NEW YORK PUBLIC LIBRARY.

THE design for the New York Public Library, which is now being erected, is the result of two competitions held in 1896 and 1897. In the limited second competition twelve firms of architects were selected from those competing in the preliminary open competition out of a total of eighty-eight. Tentative sketches of the plans of each floor were issued with the instructions. The assessors (with those selected by the competing architects), Professor Ware, of Columbia University, Dr. Billings, the librarian, and Mr. Bernard R. Green, of the Congressional Library, finally selected a design which practically adopted the whole of these suggestions. There have been variations since made, during the preparation of the contract-drawings, but these have not been of great importance and will be noticed later.

The site is one that allows of an isolated building, between Fortieth and Forty-second Streets on Fifth Avenue, with ample space for future extension, 455 feet frontage and 482 feet to the sides. The cost of the building (without fittings, etc.) was not to exceed £340,000, but it will have greatly done so — nearly twice that amount.

There are many interesting points in the conditions of competition which are worthy of study. They are extremely minute in detail. The main points determined upon by the assessors and trustees in regard to the planning are important principles, which after great study and consideration they adopted, and these make the New York Public Library perhaps the most important library now being erected in the States.

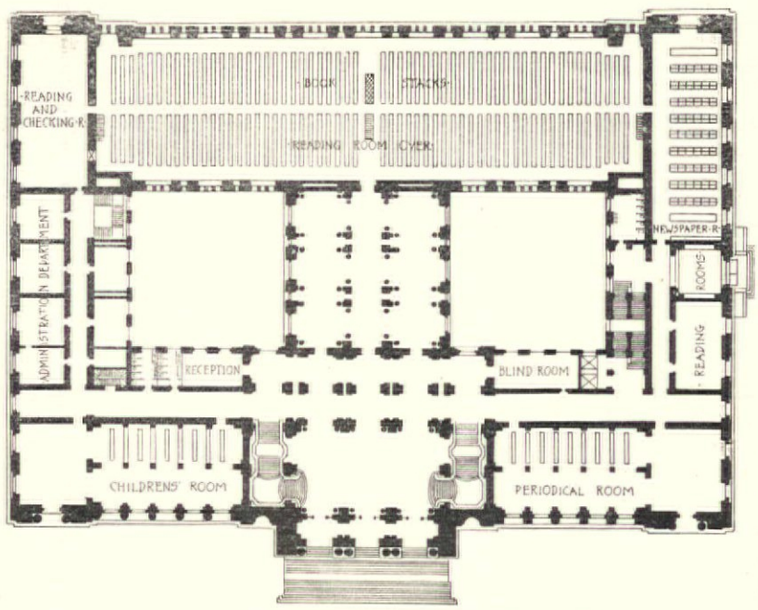
The following are three important conditions laid down, and they have not been essentially departed from, viz.: —

1. The stack was to be placed at the back, or west side, of the building, six floors in height.

2. The main reading-room for 800 readers was to be placed over it.

3. The lending delivery-room was to be placed in the basement, in the right-hand court, to be top-lighted and with entrance from the side street.

"By concentrating the book-stacks in a rectangular block on the west side, and placing the public reading-rooms above them on the third floor, with access to the stacks on each floor at the north and south ends and in the middle of the east side, the central supervision of the reading-rooms and the central delivery of books can be secured by very simple mechanism; free and direct communication between the administrative department and the book-stacks can be maintained and opportunity for easily extending both the book-stacks and the reading-rooms towards the west can be provided for whenever this may be desirable. Moreover, reading-rooms placed at the top of the building are not only quieter, better lighted, and more easily ventilated, but they can be constructed without encumbering the floor with columns." (Terms of Competition.)



New York Public Library. Messrs. Carrere & Hastings, Architects.

These are some of the advantages to be derived from the scheme, the adoption of which has resulted in a magnificent working-plan. They are immensely great, and if for one moment the plan of this library is compared with that of Boston it will be easily seen how rapidly the science of the librarian has developed. Of course, the Boston library was fine for its time. Both architects and librarians had to learn what was wanted. The library building as understood now in the United States, planned for its open-shelf rooms, rooms arranged for free access to stack, and well-fitted children's rooms, is quite a recent development, and each year progress is made towards the creation of the ideal plan.

The entrances to the basement are in Fortieth and Forty-second Streets: the one from the latter street (the north side) enters centrally and through halls directly into the lending delivery-room, 83 feet square. The west wall of this room has eight openings into the stack-room, and the delivery-counter will be placed just outside, extending the whole length of the room. The whole is top-lighted, the space above forming one of the two inner courts. Quite adjacent, between the delivery-room and the entrance, are placed the public lavatories and elevators and stairways to upper floors. The room to the north end of the stack is used for the patents-library: it is 36′ 6″ x 83′ 6″, and is really a continuation of them. The first floor of the stack is level with this basement floor. It is 297 feet long by 78 feet wide. The stacks are arranged in two rows, 5 feet centres, 7 feet 6 inches clear spaces next walls, and 5 feet central gangway north and south. The stairs are arranged at the two ends and the centre; the book-lifts are also placed in the centre of the room. There are altogether seven floors of stacks, each 7 feet 6 inches floor to floor, except the top, which is 8 feet 6 inches, to allow for extra depth of reading-room floor and arrangements for the mechanical book-carrier. The height of the basement is two floors of the stack; that of the first floor, three floors of stack; and the second floor, two floors of stack.

The left, or south, entrance is used for the administrative portion of the building, and has a driveway which leads directly into the court, balancing the court on the north side. This court will be used as the automobile station — automobiles being used for distributing to the branch libraries. It is on a level with the street outside. To the west of the drive is the packing and issue room, 36 feet 6 inches wide and 83 feet 10 inches long, with a room at the entrance to it 23 feet square. Either side of the driveway outside the main building — between it and Fortieth Street — are placed at the sub-basement level, which is 13 feet in height, the coal-room, 90′ x 32′, and the engine-room, 116′ 6″ x 31′, both top-lighted.

The printing-shop, the bookbinding-shop, and store, are placed in the front left-hand corner of the building, and occupy very large areas. West of these, and lighted from the south court, are the lavatories for the male and female employés, stores, workshops, scrub-women's room, etc., and the large space between the courts is assigned to the machinery.

On the first floor is arranged the very fine exhibition-hall, 75 feet square, placed directly opposite the main entrance between the inner courts. Either side of the great entrance-hall the stairways are placed to reach the second and third floors.

The children's reading-room and the periodical-room are placed to the right and to the left of the main entrance. These rooms, which are each 125 feet long by 45 feet wide, are practically divided into three separate rooms by piers — the portion away from the window being divided into alcoves by book-cases. The south-west corner and south side are occupied by the administrative and working departments. The large room next the stack is the receiving and checking room — the other rooms being the superintendent's offices, reception-room, telephone, stores, girls' and boys' lavatories — opposite children's room.

In the north-west corner, north side, are placed, next the stack, the newspaper-room, 111′ x 37′, two reading-rooms — one 46′ 10″ x 24′, the other smaller — stairways, elevators, and public lavatories, and also a room 46′ x 18′ for the use of the blind.

The second floor contains on the south side the administrative rooms and on the north side and central block, between the courts, the special libraries and their reading and study rooms. The administrative rooms are the accessions and cataloguing rooms, adjoining the south end of stack; and the order-room, trustees' room, directors' room, staff lavatories, etc. The room for documents is placed adjoining stack in the northwest corner, and there are special rooms for economics, science, Bibles, Oriental literature, with special reading-rooms and studies adjoining.

On the top floor the great reading-rooms, as before stated, are placed. There are four of them altogether. To reach the main one, the one second in size has to be crossed, and the other two are placed at each end of the main one. These end rooms can also be reached from the side corridors. Altogether they will make, perhaps, the finest suite of reading-rooms in the world. The main one is the same size as the stack-room below, 297 feet long and 78 feet wide. It is lighted by large semicircular-headed windows on the two long sides, each 14 feet wide, 8 feet 6 inches high from sill to spring of head, the sill being 15 feet from floor. The end rooms are each 36′ 6″ x 83′ 6″, lighted in a similar way on the outer wall. The room at the approach to the main room is 78 feet wide by 84 feet 3 inches long, and is lighted by similar windows on the two sides toward the courtyard. At present little or nothing has been settled as to the fittings of these rooms, so they cannot be described.

The other rooms on this floor are for manuscripts, rare books, Americana, prints, maps, music, art and architectural books, photographs, special reading-rooms, and public toilet-rooms. There are also four large art-galleries.

[1] A paper by Sidney K. Greenslade [*A.*], Pugin student, Grissell Medallist, Godwin Bursar, read before the Royal Institute of British Architects, Monday, March 17, 1902, and printed in the *Journal* of the Society. Continued from No. 1386, page 22.

Altogether this seems nearly as perfect a library as is possible. The magnificent group of reading-rooms on the top floor, with the huge stack below; the very fine approach to these rooms from the main stairways from the first to the third floor so arranged as not to return on themselves; the position of lending delivery-room — its very direct connection with the street and the stack, and its isolation; the arrangement of the children's room and periodical-room, with their separate stacks and easy access from the main entrance; the possibility of future extension of both main reading-room and stack-room easily assured without interfering with existing arrangements — are among the very many features that call for particular comment.

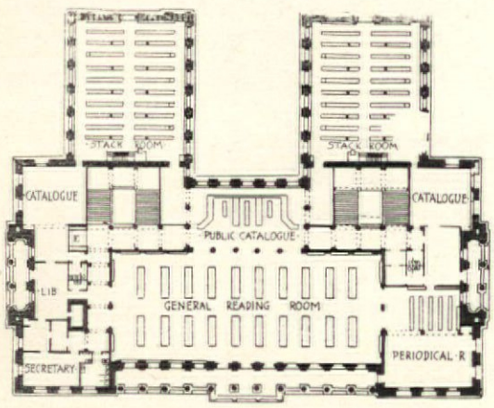
The cost will be about £660,000, and the shelving capacity is for 2,000,000 volumes. The architects are Messrs. Carrère & Hastings, of New York.

THE STATE HISTORICAL LIBRARY, MADISON, WIS.

The State Historical Library building at Madison, Wis., is an extremely well-planned building, and forms an ideal reference-library. The main building has a frontage of 210 feet and a depth of 105 feet. At the rear of this project the two stack-buildings, each 100 feet wide by 110 feet deep. It consists of four floors and a basement. Three of the floors are devoted to the purposes of the library; the basement is chiefly for storage, particularly for newspapers, and the fourth floor is allotted to the museum and art-gallery.

The building is entered from each of the four sides, and two large staircases are arranged in similar positions either side of the main hall, which is placed centrally, leading to the upper floors. Adjoining these staircases are the public toilet and cloak rooms. The other rooms on this floor are the patents and public documents, 37′ x 45′, with two floors of stack to a portion of the room; the atlases, maps, and manuscripts, 26′ x 29′; current newspapers, 18′ x 24′; newspaper-files, 10′ x 32′; the stack-rooms, only one of which is at present built; and seven special study-rooms, varying in size and capable of shelving 20,000 volumes. This first floor is level with the first floor of stack, and each of the other floors of the building come every two floors of stack in height.

The book-stacks are each 48 feet wide by 60 feet deep, and consist of six floors, 7 feet 4 inches in height, fitted with steel stacks.



Second Floor: State Historical Society Library, Madison, Wis. Messrs. Ferry & Clas, Architects.

The staircases, elevators, and book-lifts are placed at the ends adjoining the main building. The stacks are placed at 5-foot centres, and in two rows across the building, each 18 feet long, with 5-foot central and wall passage-ways. Desks are provided for the use of readers given direct access to the shelves. Each floor of the stack will shelve 40,000 volumes.

On the second floor is placed the general reading-room, 48′ x 118′ and 30 feet in height, with 20 tables 12′ x 3′, each seating 12 readers. Around the walls are shelves for 5,000 volumes. The approach to it from the stairs is particularly good, as well as the position of the delivery-counters, and the delivery-hall with the public catalogues. These are all adjacent to the main reading-room, being separated by a row of columns, and are also quite near the landing-lobbies on either side. This delivery-hall is 50′ x 28′, and on either side of it are the issuing-rooms, 27′ x 10′, connecting with stack.

In the left wing are arranged the official catalogue-room, 29′ x 44′, with entrance to stack-room, the librarian's office, 15′ x 26′, with other offices, all adjoining.

In the right wing opening out of the reading-room, is the periodical room, 39′ x 45′, with its own double-storied steel stack placed in the rear of the room, the front portion being fitted up for readers.

On the third floor, owing to the general reading-room going up through the two stories, the floor-space is greatly reduced. In the left wing is the lecture-room, 30′ x 39′, to seat 200. Over the delivery-hall is a room for art and genealogy, 18′ x 50′, with two studies either side, and divided off from the visitors' balcony overlooking the reading-room by a low railing. In the right wing are six additional special study-rooms.

Ultimately the building will house 675,000 volumes.

Architects: Messrs. Ferry & Clas, Milwaukee.

UNIVERSITY LIBRARIES.

The two buildings that are particularly worthy of attention are both in New York, the one belonging to the Columbia University and the other to the University of New York. They are not unlike in plan, both in general outline taking the form of a Greek cross. The great central reading-room, in one case octagonal and in the other circular, is the motive of the design in each building. Special study-rooms, with their books stacked around them, or near them, are an important feature of both these libraries, and in each are treated in a different way.

Often a special library-building is erected for a special subject. The recently-erected library of the Law School at the University of Pennsylvania, Philadelphia, is an interesting example.

COLUMBIA UNIVERSITY LIBRARY.

The Columbia University Library building is, perhaps, the most monumental of those yet erected in the United States, the one at the sister university of New York being much smaller, and only in that way taking a second place. The outline of its plan is that of a Greek cross, the arms being very short and wide, the width across them being 200 feet.[1]

The great feature of the building is the magnificent domed reading-room placed at the intersection of the arms of the cross. It is octagonal in form, the four sides at the angles being shorter than the others, and the whole is covered by a great dome. The lighting is from four very large segmental windows following the lines of the main arches at the sides. These windows are in the outer walls of recessed spaces, following the arms of the cross, the outline of the main building.

The main entrance to the building is approached by terraces of steps, 52 altogether, through the magnificent entrance-portico of 10 Greek Ionic columns. This is on the main floor-level of the library. There are other entrances in each of the four corners of the building at the basement-level, and it is these entrances that are generally used by the students, who reach the library from various parts of the grounds. A staircase at each of these entrances reaches the great corridor which surrounds the reading-room, and from which it is approached by the reader from the side opposite the catalogue and delivery space, in the left-hand arm of the cross. This corridor is 10 feet wide, and is separated from the reading-room by four marble columns in each of its four open sides. Between these columns are arranged bookcases, forming screens between the corridor and the room. In two cases only are there openings, one opposite the main entrance, where a locked gate is placed, with plate-glass, so as to allow visitors to view the room without disturbing the readers, and the opening opposite the delivery-counter, for the use of the readers and attendants.

It was originally intended that the assistant-librarian's desk should occupy a raised position in the centre of the reading-room, as at Washington, but it was abandoned at his request, and it is now placed on the right of the entrance to the room, with staircase and lifts to stack-room below adjacent. The reading-room is 75 feet square, with octagonal angles, and accommodates 152 readers. The tables are arranged in concentric circles, four rows altogether. The readers on the outer ring have each allowed them a space of 2 feet 9 inches, the second row 2 feet 11½ inches. The tables from front to front are 5 feet. They are sloped slightly, and between each reader is a slight tapering division-bead. The oak bookcases in the reading-room contain 12,000 volumes, all reference-books, divided into various classes, each case being distinctly labelled. The large central octagonal case has shelves both inside and out, as well as a case within it in which the bound magazines and reviews are placed. The cases between the columns are placed on a marble plinth in the form of two steps 1 foot 9 inches high, the total height from floor being 10 feet 1½ inches to top of cornice, the height in the clear for books being 6 feet 6 inches. The spaces between the first and second steps of plinth are fitted with gratings for extracting the foul air from the room.

On the same floor as the reading-room the arms of the cross are arranged into the following rooms, viz, the entrance-vestibule, with the trustees' room on the right and president's public office on the left, occupy the south arm; the architectural library is placed in the east arm, with a separate reading-room, and balancing the latter are the Greek and Latin seminar rooms; the law library, with its conference-room and dean's office, is placed in the north arm; and the left is chiefly administrative — librarian's room, accession room, cataloguing and delivery and temporary periodical room, which eventually will occupy the space used by the law-library when a special building is erected for it.

The stack-room is placed in the basement under the main reading-room. The stacks are of oak, and run from north to south, with a 5-foot central gangway east to west. They are 18 inches wide and 2 feet 11 inches between. The shelves are 2 feet 6 inches long, having 2-inch divisions between them. They are 8¾″ x ¾″, the first one raised from the floor 3 inches. The floor to the second stack is of wood, carried on wooden joists. The height from the lower floor of stack to the floor of reading-room is 15 feet 4 inches. Each floor contains 75,000 volumes. These stack-rooms are inadequately lighted with borrowed lights from the corridors, and, therefore, have to depend on artificial lighting. There is also a stack-room below

[1] See plan and exterior view, *Journal* R. I. B. A., Vol. VI, pp. 220-21.

the law library, from which it is reached by stairs, with book-lift adjoining, adjacent to the attendants' desk.

The law library is 60′ x 37′ 6″; it is fitted with tables 2 feet 11 inches in width and 14 feet in length, 2 tables to each of the 7 rows. They are 4 feet 1½ inches apart, and seat 6 readers on each side. The room is panelled to a height of 7 feet 6 inches on window side and 10 feet 6 inches around the three other sides, with shelving fitted-in. Extra space for readers is obtained by a small iron gallery, about 5 feet 6 inches in width, placed around three sides of the room, fitted with 16 small tables accommodating 2 readers each. From this gallery doors on either side lead to the law-professors' rooms. The number of readers provided for is: in gallery, 32; main floor, 189; total, 221.

The architectural library is about 37′ 6″ x 65′, capable of shelving 12,000 volumes. It is divided into five bays by cases forming alcoves, and tables 3′ x 9′ are placed in each. Those next the outer wall are well lighted, but the ones in the inner alcoves are dark. The division cases separating alcoves next windows are 2 feet wide and 8 feet 11 inches to top of cornice. They have 4-inch panelled ends, and 2-feet 6-inch shelves in the clear between 1⅞-inch uprights, and are four divisions in length. The shelves are of ¾-inch wood, grooved for iron runners. Portions of the upper walls are also shelved, and where this occurs an iron gallery, 9 feet 4 inches from floor, is placed. The total height of room is 18 feet, and the accommodation provided is for 40 readers.

Over the architectural library and in the corresponding arm over the delivery-room are placed the seminar rooms, with their stacks. These are very well schemed. Each room is 12′ x 14′, and there are seven of them: the whole of them can be thrown into one room, being divided by 3-inch oak-framed divisions, which can be drawn out easily. On the inner sides of these rooms are arranged the steel stacks, with a passageway next wall, and from which, between the stacks, the rooms are reached. One table is placed in each room, 3′ 10″ x 7′ 6″, to seat 8 readers, and in a corner of each of the rooms is fitted a case with 12 locked drawers and 27 open pigeon-holes for students' papers.

There are two floors of stack, with a total capacity in each wing of 100,000 volumes.

On the third floor are the lecture-rooms. Eventually, the two wings over the seminar rooms will be fitted in a similar manner to them: at present they are only temporarily divided. The galleries to the main reading-room are at this level and are used partially for stacking books and for visitors viewing the reading-room. The stacks in these galleries are in two heights, and in the four contain 64,000 volumes.

Architecturally this building is very fine, and to obtain this fine effect it is evident that one or two utilitarian points have been rather sacrificed; this applies particularly to the arrangements for the storage of the books below the main reading-room, where light is greatly needed. On the other hand, the general arrangements of the reading-rooms with their fittings and the special study-rooms are all particularly good.

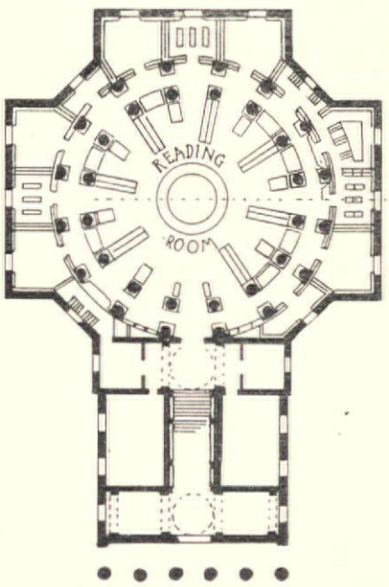
The total shelving-capacity for books is for 1,050,000 volumes, and the cost of the completed building was £240,000.

Architects: Messrs. McKim, Mead & White, New York.

NEW YORK UNIVERSITY LIBRARY.

The Library at the New York University is much smaller than the Columbia University Library, and the scheme of the plan is decidedly more compact. The general outline — that of a Greek cross — is the same, the entrance-arm being longer than the others. The extreme width of the building is 102 feet, and from the outer face of the column of the portico to the west wall 160 feet. As in the Columbia Library, the great feature is the domed reading-room, but it is circular on plan instead of being octagonal, and the books are stacked round about it and not below, and, are, therefore, generally more accessible. The main entrance is from the east front, and from the large hall, with its staircases either side leading to the auditorium below, a broad marble staircase of 24 steps 12 feet wide leads to the reading-room. Before the reading-room is entered a small domed vestibule is reached, and from it to the right and to the left are the chancellor's and librarian's rooms, and over these rooms are the two cataloguing rooms and the periodical and newspaper reading-rooms.

The reading-room is 54-feet 3-inch diameter to the inside face of the 18 marble columns, and has an ambulatory around 5 feet between the faces of the columns. Between the columns glazed cases for large books or portfolios of the same height as the tables are arranged, so that readers in reaching their seats do not disturb one another, the approach to the tables being only between certain of the columns, conveniently arranged near the stairs to the seminar rooms and the main entrance to the room. The central portion of the room is occupied by a circular table 20 feet in diameter, seating 24 readers. There are besides 8 tables 12′ x 3′ 8″, each seating 8 readers: these are placed radiating towards the centre, and between these long tables are smaller ones, 3′ x 5′, each seating 4 readers, the seating-capacity of the room being for 120 readers. The delivery-desk is placed facing the ambulatory and occupies the second bay to the left on entering; adjacent to it are the stairways leading to the various seminar and reading-rooms, and it has telephone-connections with all the rooms in the building. The two bays either side directly on entering are fitted for the card-catalogue, and suitable tables for its use are placed adjacent. The whole of the space between the columns of the wall of the ambulatory is shelved for books. It is three tiers in height, each 7 feet 6 inches, with galleries over the ambulatory to the second and third floors. The first galleries are arranged between the columns, one to each bay, and only project slightly. Each bay is divided into three divisions vertically, the central division being hung as a door and opening with all its books inwards. The second gallery, with its glazed floor, goes around the whole room, and nearly projects to the outer face of the inner columns. Thus, nearly the whole of the circular wall of the main reading-room has been utilized for the storage of books. The doors leading to the book-rooms are themselves book-stacks swinging on central pivots.



Main Floor: New York University Library, New York N. Y. Messrs. McKim, Mead & White, Architects.

Around the base of the dome is another gallery where thousands of books, when necessary, may be shelved. Unlike the Columbia University reading-room, here the lighting is by a circular skylight 20 feet in diameter in the centre of the dome.

From the ambulatory on the main floor and the galleries on the third and fifth floors are arranged 18 seminar rooms, which are devoted each to a special subject. As will be seen from the plan, these rooms are curious in shape, averaging 18′ x 14′, each provided with 2 tables, 3′ x 5′, for 4 readers. Shelving is placed all around the room, and at a height of 7 feet 6 inches, a glazed gallery with more shelving and stacks projects from each wall. The capacity of the shelving already installed in the building is for a quarter of a million volumes. Should it be necessary at any time to increase the shelf-room, this can be done by using the large auditorium below the reading-room for stacks, and would give the library a total capacity of a million volumes. The galleries to this auditorium are sometimes used as a reading-room.

The principle of the seminar rooms is excellent. They are very conveniently arranged, but the shape of them is awkward and the size small, and the upper ones with the top lighting become very hot in the summer.

The arrangement of shelving between columns to circular wall of reading-room, with the galleries for approaching it, is very well managed, and the effect good. The position of the card-catalogue so near the entrance and the way it is fitted into the wall is most convenient.

Architects: Messrs. McKim, Mead & White, New York.

PENNSYLVANIA UNIVERSITY LAW LIBRARY.

The library of the Law School at the University of Pennsylvania has a remarkably well-arranged and convenient plan. It is a building of two stories, with a frontage of 175 feet and a depth of 105 feet. Practically, the whole of the first-floor plan is occupied by lecture and class rooms, and it is the second-floor plan, where the book-stack and reading-rooms are placed, that calls for comment.

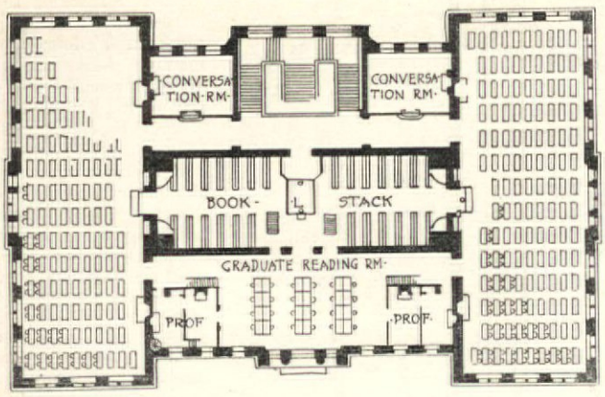
The book-stack occupies the centre of the building, there being entrances to it from each of its four sides, the landing of main staircase, the two large undergraduates' reading-rooms at each end of it, and the graduates' reading-room opposite the staircase and entrance. To the undergraduates' reading-rooms are delivery-counters, 2 feet 4 inches wide and 2 feet 9 inches high, and with gates at sides, each with an attendant. From the graduates' room there is free access to the stack-room.

There is room for five floors of stacks: at present, only one floor is fixed. The width between stacks is 3 feet 6 inches and the central gangway is 7 feet 6 inches. The librarian's office is placed in the centre and is enclosed by glazed screens. The whole is top-lighted the full length, the roof being a simple steel-trussed one, and additional light is obtained for the two top floors by windows over the main staircase. All the entrances from reading-rooms to stack-room have two iron shutters.

Either side of the main staircase are two conversation-rooms, each 22′ 6″ x 18′. The two large undergraduates' reading-rooms are each 42′ x 100′, well lighted on three sides. Each room is fitted with 126 dual desks for 252 readers. These desks are 5 feet 4 inches long, 2 feet wide and 2 feet 6 inches high. The space between front to back is only 1 foot 8 inches and the gangways between them 2 feet 5½ inches. Each desk has two locked drawers, and is fitted with a small brass upright ticket-holder and electric-bell to delivery-counter. A book being wanted by a reader, the ticket with number of desk is

inserted in the holder, and the bell to the attendant's desk rung, which gives the number of row of desk; a boy is then sent to collect the ticket, and the book is brought without the reader being disturbed. The desks in these rooms are much too crowded.

The reading-room for the graduates is much smaller — only 27′ x 48′, accommodated to seat only 24 readers. The desks are arranged



First Floor: Library of the Law School, Philadelphia University, Pennsylvania. Messrs Cope & Stewardson, Architects.

in 3 rows each, seating 4 readers on a side: they are 5 feet wide and 18 feet long. There are 3 drawers to each desk, the tilted drawers for books on the left of the reader being a particularly happy idea: practically, it forms a shelf for 8 or 9 volumes without crowding the desk. The lavatories are arranged in a mezzanine floor off the half-landing. There are 4 professors' rooms either side of the graduates' reading-room and 4 more over them. A gallery connects these upper rooms with the stack, passing through the graduates' reading-room.

Architects: Messrs. Cope & Stewardson, Philadelphia.

[To be continued.]

PARIS

ARCHITECTURE AT THIS YEAR'S SALONS.

A LITTLE while ago, M. de Baudot held a "conference" on contemporary architecture. It troubled him to see that our times had no new style of architecture, seeing that it had at its disposal new kinds of material which could lend themselves to new forms. He was wrong in not doing justice to the efforts made to get away from the superannuated Classic style which lends itself ill to the solution of modern programmes. The Guimards, Sauvages, Plumets and many another have sought, and sometimes have found, new forms. M. de Baudot himself has indicated what paths might lead to the creation of the style of our times. But one must know how not to be too exacting at the start. We are passing through a time of transition, whence, perhaps, something will issue. We must know how to wait. In this connection, and from the modern standpoint, the small amount of architecture exhibited at the Salon of the Société Nationale is far more interesting than the great quantity of banalities hung on the walls of the Artistes Français.

Making exception of the archæological work by M. Eustache, and the restorations of the ancient theatre of Louis by MM. Gaudet and Prudent, making exception also of a quantity of beautiful water-colors which are agreeable to the sight, there remain but a few good studies and these are little calculated to revolutionize the art. There are some which make us share the regrets which M. de Baudot expresses. Take the case of M. E. Meyer, who was called on to solve a programme which was essentially modern, — a sanatorium, and more than this, this sanatorium was to be built in the environs of Paris. Here was the very chance to seek for something new. The sanatorium is a new thing, and the present demands of hygiene have not been satisfied by the solutions of former times. Now, what does M. E. Meyer do? He draws his inspiration from Arabian architecture, and makes a mosque with flat roofs, small cupolas and minarets. No element of the style is lacking. Everything is very pretty, very brilliant, well studied, but deplorable from the chief point-of-view. But, my dear M. Meyer, we are not in Algeria, we are in France, in the environs of Paris, and this is the year of grace 1902.

The *hôtel* built by M. Guinot is also a very interesting study in modernized Renaissance. But consider how very contradictory are these two words, one beside the other. The architect who, in 1902, makes a Renaissance façade must, behind these walls, which belong to another epoch, satisfy the tastes and needs of the day, and prepare a modern plan. There are very many chances if a Parisienne is to inhabit this *hôtel*, that she will introduce in it a certain element of the "new art," certain chiffons, certain pieces of furniture with which the Renaissance style will surely make *mauvais ménage*. Just as it is interesting to come upon a building, Renaissance or of any other style you please, dating from a given epoch, and giving us, in consequence, information concerning it, just so it is useless to copy it, or which is worse, to draw inspiration, from the styles of antiquity in satisfying modern needs.

A villa at St. Cloud, by M. E. Arnaud, deserves attention for the ingenuity and good sense shown in its composition. Another, by M. Sauvestre, on Lake Léman, shows that architects can very easily discover elegant and interesting forms, without borrowing them from past times.

Scruples overcome me as I formulate these criticisms. Am I not unjust towards certain of my confrères who have had to yield to the demands and caprices of their clients? It is plain that it is difficult for an architect to build a "modern" villa for a client who demands a Renaissance *hôtel*. I do not deny these difficulties which paralyze one's efforts and intentions. The right of the client who pays the bills cannot escape recognition, and M. Guinot may have been obliged to submit himself to them. But M. Meyer would have difficulty in making me believe that any one demanded he should prepare a Moorish construction to shelter a sanatorium in the environs of Paris. We ought to combat a certain kind of ideas which our clients may have, but we should not be the first to drag them into paths of illogicality and absurdity. And unfortunately, we find at the Salon des Artistes Français some deplorable examples.

Many artists have protested against the scheme for the construction of a bridge over the Seine, where it would mask the marvellous perspective of the Cité from the Pont Neuf. What must one think of an architect who not only accepts this idea, but still further aggravates it by adding at the very middle of the bridge a mediæval tower, which will not only mask, but entirely suppress, with a single stroke, the graceful silhouettes of the Palais de Justice, of the St. Chapelle, and of Notre Dame. I do not care to give the name of the author of this vandal proposition, but I am sorry that any such idea could have sprung from the brain of any architect, and I declare that our artistic education has very far to go before the renovation desired by M. de Baudot and many others is accomplished.

M. Picq is much chagrined over the desertion that has befallen the garden and galleries of the Palais Royal. Formerly the centre of life and movement, they have become dead and deserted. M. Picq would like to resuscitate them, and exhibits a means of doing this as conceived by him: large openings on the streets neighboring the garden which at present is enclosed by buildings, creation of rampes accessible to carriages, etc. This attractive scheme may perhaps be realized, but it is not likely that it will be undertaken immediately.

Before finishing this brief account of the Salons of 1902, it gives me pleasure to say that the remarkable work by M. H. Eustache has been awarded the medal of honor at the Salon des Artistes Français. For their very interesting restoration of the Salle de Louis, MM. Paul Guadet and Prudent have obtained a first medal. The same recompense has been awarded to M. Bruel, for a restoration of Roman buildings in the southwest, and on the Palatine.

At the Congress of 1902, the Société Centrale des Architectes has, for its part, awarded grand silver medals to M. Eustache, and to MM. Paul Guadet and Prudent. So these artists, at least, have not seen their efforts pass unrecognized, a thing which, alas, does not always happen to architects.

CHICAGO, FIFTY YEARS HENCE.

"WITH about two years' residence in this city, I think our President must have meant to be funny when he called on me for 'Reminiscences of Early Engineering Works in Chicago.' But time has no beginning and no end, and past and future are but questions of the point from which you take them. To meet the challenge, then, I will simply shift this point to 50 years ahead, and speak of the 'Early Engineering Works in Chicago' from a standpoint in the middle of the century.

"I would first note, what perhaps is of most interest to those present: the way the city got its subway. The matter was discussed in the early part of the century. The city-engineer had one plan and other engineers different plans, but the telephone-companies, gas-companies, electric-light companies, water-pipes and sewer-mains went right ahead and used up all the space underground, so that when the public decided to do something there was no space left underground to do it in. This was a difficulty until an engineer of that day suggested that, as they could not make a subway below the ground, it would be just as well to put the sidewalks of the city up about 15 feet higher and have a subway already excavated, with the ground-floors of the tall buildings as basements.

"As the municipal street-car service of that day had a time-card of about an hour from 39th Street to Adams Street, it was very desirable to have the air-spaces between the raised sidewalks to sell to a new traction-company that would really fill some of the requirements of rapid transit. This, when sold, brought so large a sum that those who worked it through the Council actually could not get all of it, and the city then found itself in possession of a large sum to spend on improvements.

"The first thing to improve at that time was the Chicago River,

which had been so improved by the Sanitary District that its condition was intolerable. An expert commission was appointed to consider this problem, and a venerable member of that commission organized a search into the old files of the District. This unearthed a report of L. E. Cooley's of 1901, which covered the ground very thoroughly, and the commission made quite a reputation by recommending it. The work was carried out substantially on the project outlined by Mr. Cooley a quarter of a century earlier.

"Following this, it began to be apparent to the Government that an 8-foot waterway in the Illinois River was hardly suitable to connect with the 24-foot waterway across the Chicago divide. At that time, also, the position of Congressman was so much less profitable than that of Alderman that it was not difficult to get really intelligent men to send to Washington, and the interests of Chicago in a waterway to the Gulf began to be considered. The improvement of the Illinois River was developed just as it had been outlined in the ancient history of 1885.

"The lake-to-the-gulf waterway had quite an interesting history. The thousand miles from Cairo to New Orleans had been improved so greatly, at an expense of some eighty million dollars, that the depth was about 3 or 4 feet less than when the work was first started. There had been built an earth embankment along the river, shutting off the floods from the bottom-lands, and the high-water flow-line had risen until it was about up to the eaves of the houses of the people behind the levees.

"In that chapter of accidents which make the great floods of a river, the spring rains and melting snows came down the frozen slopes of the Allegheny, just as heavy rains in the northwest brought the Missouri and Arkansas in flood to join the Ohio, while warm weather in the lake district sent down the spring floods from the upper Mississippi and Illinois rivers. The earth embankments of the lower Mississippi went down before this combination, and the flood-waters swept over a thickly settled and highly cultivated district 40 to 60 miles wide and 500 miles long, from Cairo to the Gulf.

"This was the end of the plans of the Mississippi River Commission and a more rational project for improving the river and protecting the valley was adopted. In this a deep waterway was easily secured and finally joined to the improvement of the above from Chicago to the Mississippi.

"It is only recently that I went down the line in an ocean steamer and saw this dream of the centuries realized. But the weight of years was upon me and I was alone with the memories of its beginnings; perhaps it was malaria; but I summed up the history as follows: A great work is a great misfortune to the engineer who has the bad luck to first conceive it. It drives him to a life of effort without reward; dooms him to continued disappointments, and promises him that he will never live to see it accomplished."—*Mr. James A. Seddon, in the Journal of the Western Society of Engineers.*

ORIGINALITY *VS.* TOMFOOLERY.

NEW YORK, N. Y., July 21, 1902.

TO THE EDITORS OF THE AMERICAN ARCHITECT: —

Dear Sirs,— Looking over your interesting weekly of July 19th, I was struck by your reply to an "exchange" on originality in architecture.

We all know that the primary colors have always existed and that the alphabet dates back a few thousand years, but still our artists and writers produce original works and surely no one will doubt the beauty of Shakespeare, though his very letters and words are identical to those of the Bible, the Iliad, etc. The colors of a Puvis de Chavannes are the same as of a Raphael; but no one will deny the claim to originality and beauty in Shakespeare and Puvis de Chavannes, and I cannot see why the underlying principles in architecture cannot be applied in producing results of equal beauty and originality. To discard the dictionary and the grammar, coin new words and new constructions, or to put the cart before the horse, or "to wear one's shoes on one's head," would be more accurately called *tomfoolery* than "originality." No branch of art or literature is more closely associated with man's life and pursuits than architecture and none more expressive and none more influenced by it; and consequently to produce beautiful and original works in architecture man must live beautiful, distinctive or original lives, and architecture must be made to conform to it and express it in all its phases; beauty and originality in architecture are results and not products, and therefore to strive for "originality for the sake of originality" is expressive of tomfoolery and not to be noticed. The lives of different nations that have lived beautiful and distinctive or original lives are wonderfully written in their architecture, as in the case of the Greeks and our own colonials, and while our Indians have been original their national life can hardly be called beautiful and their art clearly expresses it.

I might say that I am prompted in writing you this by a desire to arrive at the root of the argument, as I do not think the reply usually made that originality necessarily implies freak or absurdity elevates our profession, but rather stamps it as commonplace, and it would give me great pleasure to have your further views on the subject.

Very truly yours, ABNER J. HAYDEL.

[MR. HAYDEL very nearly expresses our views. Our quarrel is with those who make originalty not only their first, but their only aim, as for instance many of the expositors of "l'Art Nouveau." — EDS. AMERICAN ARCHITECT.]

A QUESTION OF COMMISSION.

JAMESTOWN, N. Y.

TO THE EDITORS OF THE AMERICAN ARCHITECT: —

Dear Sirs,— Kindly advise me on the following: —

If a Boston architect is requested to make rough sketches of a parochial-school building, "subject to the approval of the building-committee" and not to exceed $14,000, and submits sketches which are rejected by the building-committee on the ground that the arrangement is not suitable, and also that the building would cost very considerably more than the specified sum, is he entitled to a compensation, and, if so, how much? Your usually sound judgment and opinion in this matter will be highly appreciated.

This case, as you are aware, is a very old one, but I cannot recall having seen your opinion expressed on this vital question, and I am anxious to know to just what extent the architect is entitled to remuneration and to what extent the committee is liable under facts as stated above.

An early attention will be greatly appreciated.

Yours truly, INQUIRER.

[In general, an architect who submits sketches "subject to approval" is understood to agree tacitly that he will not claim any pay unless they are approved. In the present case, the agreement with the building-committee seems, in addition, to have included a covenant that the cost of erecting the building should not exceed fourteen thousand dollars, and failure to comply with this condition, at least within a reasonable margin, would entitle the committee to reject the sketches without paying for them, on the ground that a man who has agreed to furnish sketches for a building to cost fourteen thousand dollars does not fulfil his contract by furnishing drawings for one which would cost, say, twenty thousand; and his failure to perform his part of the agreement releases the other party from any promises that he may have made in consideration of fulfilment. We do not see, therefore, how the architect in this case can claim any compensation. — EDS. AMERICAN ARCHITECT.]

NOTES & CLIPPINGS

THE TUNNEL BETWEEN SCOTLAND AND IRELAND. — The proposed railway-tunnel between Scotland and Ireland, judged as one element of the general schemes which are now being mooted for shortening the distance of the ocean passage between Europe and America, is placed in somewhat the same category as the late Austin Corbin's dream for the creation of a great terminal port at Montauk, at the eastern end of Long Island; there being this difference, however, that when judged on that ultimate basis to which all such schemes must come — financial practicability — the Scotland-and-Ireland tunnel is even less feasible than Corbin's project. The cost of the tunnel is estimated by the contractors at $50,000,000, exclusive of interest, and, as matters now stand, there is not nearly sufficient traffic, either freight or passenger, to enable the scheme, if completed, to earn interest on the cost of construction. Nevertheless, in view of the rapid growth of commerce and the vast accumulation of capital seeking investment, it is conceivable that conditions may arrive in some future day that will guarantee the construction of a 34½-mile tunnel such as this. The engineering features of the tunnel were discussed recently in a paper read by James Barton, M.I.C.E., before the International Engineering Congress at Glasgow. Of the three possible locations for the tunnel, the one selected lies between Wigtonshire, Scotland, and the Irish coast, at a point where the distance from shore to shore is within 23 miles. The maximum depth of water varies, according to the line selected, between 480 and 900 feet. The route forms a through line between Carlisle and Belfast, and has the advantage of providing the best route from Scotland to the whole of Ireland, and from the north of England to Ireland. The survey for the tunnel proper commences 5 miles from Stranraer railway-station and finishes 5½ miles inside the shore line of the Irish coast, the total length of the tunnel being 34½ miles. Leaving the tunnel, the line extends for 10½ miles to the city of Belfast. The total length from Stranraer to Belfast is 51½ miles, 34½ of which is tunnel, and 25 of it beneath the sea. The roof of the tunnel is 150 feet below the sea-bottom. The proposed heading is 7 feet high by 10 feet wide. It is expected that the portion of it which is driven through the Silurian will be cut as rapidly as the Simplon tunnel, while progress through the Keuper marls is expected to be more rapid. It is estimated that the whole of the heading would be completed in less than ten years, and the tunnel finished in about twelve years. This estimate is based upon a comparison of the speed of driving 4 notable tunnels. The Mont Cenis was driven at the rate of 6 yards a day, and at a cost of $1,120 per yard. In the St. Gothard the maximum speed was 10 yards a day, at a cost of $710 per yard. In the Arlberg the maximum speed rose to 12 yards a day, while the cost was reduced to $535 per yard; and it is expected that on the Irish tunnel, judging from the quality of the material to be passed through and the improved methods now being used on the great Simplon tunnel, the speed will be increased and the cost per yard reduced still further. As to the question of water entering the tunnel, although the uncertainty on this point is admitted, the author of the paper does not consider that the difficulty will be a serious one. No water-leakage in any great quantity occurred during the construction of the Severn or the Mersey tunnels, at least in those portions of these tunnels that were immediately beneath the sea; and it is believed that the sea bed below the Irish tunnel has probably closed all faults in the rock sufficiently to keep out sea-water in any but easily-handled quantities. The line will be operated electrically from power-stations located near the main shafts at each end of the tunnel; and it is proposed to run trains at a speed of 60 to 70 miles an hour, thereby reducing the time in the tunnel to about half an hour. — *Scientific American.*

PLANTING ANTIQUE FURNITURE. — Occasionally one hears of an apparently honest countryman who plants sham antique oak in inns, farmhouses and cottages to ensnare the unwary; and then the prices that are obtained, after the reluctant consent of the family to part with the treasure "that belonged to grandmother," or "came from the big house," would gladden the heart of many a poor struggling broker who is trying to earn an honest livelihood. One of our leading artists told the writer that he had been "had" by a man dealing in pigs in X., a small village three miles from any railway, a very quiet place, and certainly one where the victim did not expect to find guile. This countryman would have dower-chests made from old oak, taking care that parts showing rottenness and age could be pointed out as a proof of genuineness, a place having been cut out for one of the large old locks and then partly filled up, a small lock some forty years old fitted, and half-broken old hinges added to secure the lid. These pieces would then be exposed in the yard leading to the sty as though of no value in their owner's eyes, and the action of the weather, mud and filth soon completed the artistic effect. Now, oak chests with quaint carving are always desirable pieces to possess, and when the artist, who was in the neighborhood sketching, casually asked a resident if he knew of any old oak, he was told that the pig-dealer had a rare old chest in his yard, which, no doubt, could be bought cheaply enough. Away went our connoisseur of oak, and found what purported to be a fine old chest decorated with most unusual carving, and having, moreover, linen-pattern panels. From the position it occupied, he imagined he could buy it for a sovereign; but the owner, used to dealing with men in various markets, chaffed the artist in bluff, honest fashion, and told him plainly he had thought nothing of it, but he was a dealer — a pig-dealer — and sharp as any one, and knew an artist-chap wouldn't want to buy an old thing like that if it wasn't worth more than he knew; and so on, until eventually he extracted £12 for the *trouvaille;* and, after an attempt to extract another five shillings for cartage, delivered it to the railway-company, who forwarded it to the artist's address in London. When, in the privacy of the studio, it was thoroughly washed and cleaned, it stood revealed a "fake," and a dealer who eventually purchased it from its disgusted owner for £3 candidly observed that he had given a very good price, as such things cost from the maker, when new and in proper condition for sale, £4 10s. — *Chambers's Journal.*

THE LARGEST SCHOOL. — Which is the biggest school? A writer in *Sandow's Magazine* claims that the Jews' Free School, Spitalfields, is the largest school not only in London, but on earth. There are 44 classrooms for boys and 27 for girls. Each room is fitted as completely as modern invention can make it. The fact that the school has never been closed owing to the spreading of any epidemic indicates the sanitary perfection of the enormous structure, now covering two acres of ground.

CAN'T RECOVER FOR DEATH IN ELEVATOR. — The Appellate Division of the New York Supreme Court has just handed down a decision affirming the judgment of the lower court and setting aside a general verdict in favor of the plaintiff in the case of Walter H. Griffin, against William De Forest Manice, owner of the building at the northwest corner of Pine and William Streets. Griffin was Secretary of the United States Fire Insurance Company, with offices on the eighth floor of the building. On December 6, 1898, while in the elevator of the building, he was killed by its fall to the ground floor. The defendant admitted the facts cited, but declared that the accident was not due to negligence. A jury rendered a verdict of $7,500, but Justice Russell set it aside. The opinion is written by Justice McLoughlin, with Justices Van Brunt and Ingraham concurring, and Justices O'Brien and Hatch dissenting. — *N. Y. Tribune.*

DEEP BORINGS IN THE UNITED STATES. — The deep well-borings of the United States, made for water, oil and gas, are the subject of a statistical report by N. H. Darton, in the series of water-supply and irrigation papers of the United States Geological Survey. All wells 400 feet or more in depth are carefully listed; depth, diameter, yield per minute, and other characteristic data are given, and many instructive details are noted indicating for what purpose the borings were originally made, the character of the product obtained, and whether the wells are in use or abandoned. The large product of natural gas in the East and the West, the enormous output from the oil-fields, in California, Texas and the East, and the considerable and indispensable water-supply furnished by the deep wells on the plains and in the arid and humid States, make concise and accessible information of this nature valuable for economic and scientific purposes. — *N. Y. Evening Post.*

DANGER FROM GAS-LEAKAGE. — An interesting discussion on gas-leakage and its possible effect upon health was held at a recent meeting of the New York County Medical Society. Annually in the large cities the gas-companies expect to have a leakage of over one thousand millions of cubic feet of gas. In recent years this has become much more dangerous in its possible effects than in the early days of gas-lighting, when ordinary coal-gas was employed. The gas produced in closed retorts by the destructive distillation of coal contained only a very small amount of the most poisonous ingredients, the carbon monoxid, or blue gas. Since water-gas has come to be employed almost exclusively for illuminating purposes the percentage of carbon monoxid present in illuminating-gas is over 30 per cent. There has been a suggestion in recent years that pure water-gas should be employed in cities for heating purposes. In order to be useful for illumination, water-gas must be carburetted — that is, saturated with certain naphtha derivatives. It is these substances which give the water-gas, as made at present, its characteristic penetrating odor. They also somewhat dilute the more poisonous gases which are present. The gas-expert who discussed the subject at the meeting referred to said that "if pure water-gas was to be supplied for heating purposes, the only safe place to live in New York City would be outside of it." Present conditions in our large cities add to the dangers of gas-leakage. Our pavements, especially in quiet residence streets, are usually asphalt, and are thoroughly impermeable. Gas that escapes from the mains is confined beneath the streets until it finds its way into the houses or into the sewers. There is no doubt that severe anæmias are becoming more frequent in city life. Dr. Lloyd pointed out at this same meeting that some of these anæmic conditions, associated with febrile temperature, malaise and headache, are traceable almost directly to sewer-gas. As it is well known that ordinary sewer-gas does not affect the health of workmen who are many hours each day engaged in the sewers, it would seem that only when large amounts of carbon monoxid find their way into the sewers, and thence into the houses, for the gas is highly diffusible, that so-called sewer-gas takes on such pathogenetic influences. — *American Medicine.*

COACHING ON GOOD ROADS. — But apart from all other considerations, the true way of making roads was not understood. This was not gained until the beginning of the last century. Macadam was the genius who evolved it. It is that of to-day, familiar to everybody, by which a hard and elastic surface, admitting of easy repair, is gained by the use of stone broken to a uniform, cubical size and shape, and gently sloped in the laying from the centre of the roadway to the ditches or channels at each side. What it meant may be judged by the old coaching results that immediately followed. In 1803 the distances between London and Shrewsbury, 154 miles; between London and Exeter, 171 miles; and between London and Manchester, 187 miles, were each done in a day. The roads were well maintained by the Turnpike Trusts, which were invested with powers for construction, management, and repair, and for taking toll for this purpose at the once familiar turnpike-gates. These in turn have been done away with, and maintenance provided for by a district rate. — *London Globe.*

NOTES AND CLIPPINGS. 40

MR. J. C. PUMPELLY writes earnestly in the New York *Evening Post* in favor of trade schools. We have in this country a certain number of manual training schools, where children are taught, in general, to use their hands and eyes, but of trade schools, pure and simple, where boys and girls may learn a profession by which they can later earn an honest living, we have very few. The Auchmuty schools, in New York, were exactly what is needed; and the New York Hebrews maintain, with the help of the Hirsch Fund, something of the same kind; but that is almost all; and the vast majority of children who must work with their hands to support themselves and those dependent upon them are obliged to pick up a rudimentary knowledge of some trade as apprentices, or helpers, struggling all the while against the influence of the unions, which oppose, by every means in their power, the training of future rivals to the selfish union members, and against the churlishness of the workmen themselves, who, as a rule, instead of being willing to impart to others the knowledge that they possess, guard with ridiculous jealousy any improved method or recipe that they may have become acquainted with. The result of this discrimination against the young and friendless, which is almost universal among workingmen, is that vast numbers of children of more than average natural capacity, unable to gain even the precarious foothold of apprenticeship in any trade, are forced to seek a living by their wits, taking up whatever presents itself. In many cases, they work up, through successive stages as errand-boys, wagon-drivers or clerks, to responsible positions, but a large portion of them, without regular employment or good example, drift into a condition of dishonest shiftlessness; and the interference of the public authority is needed, not only to keep the children of poor families from idleness and degradation, and put them in the way of becoming useful citizens, but to keep in a prosperous and progressive condition the trades on which so large a part of the community depends for existence, and which it is the policy of the unions to sacrifice to the selfish interests of their own members. In the industrial competition from which England now suffers so much, and is likely to suffer much more, and from which we shall, in our turn, suffer if we are not wise in time, an immense advantage has been derived by Continental manufacturers from the trade and technical schools which have been everywhere established. It is not many years, for example, since German manufactured articles were hardly known, outside of Germany, except as cheap, rough and clumsy things, which could not be sold to anybody but Germans. The first application of German science to business was, perhaps, in the manufacture of chemical products, and it was not long before the Germans led the world in this industry. The lesson was not lost, and in metallurgy, optical work, and the designing and weaving of textile fabrics, not only the managers of manufacturing establishments, but the operatives, began to be taught, not only the theory of their business, but the best and most improved manipulation; with the result that German silks are sold, it is said, even in Lyons; German brocades are sold in India, side by side with the native fabrics; German optical instruments are regarded, all over the world, as superior to any others; German ship-building, an industry of very recent creation, rivals that of any other country, and German hardware is rapidly supplanting that of Sheffield and Birmingham in the markets of the world. All this has been the result of a few years of education of young workingmen to understand and respond to the ideas of those more highly trained in the theory of the business in which both work together. In Prussia alone there are more than three hundred of these technical schools for workingmen, and in Belgium and Luxemburg, which closely follow German lead, they are, proportionally to the population, even more numerous. It would not have taken many years of this system to put Germany at the head of the industrial world, if it had not been for the fact that rival European nations were quick to see its advantages, and to take measures for profiting by German example. In France, a great number of trade schools, teaching nearly everything, from cabinet-making to weaving, were soon established, and have begun to produce good results; while little Switzerland already swarms with "*ateliers d'apprentissage*," or small trade schools, where children are practically taught weaving in silk, wool and linen, cotton-printing, embroidery, lace-making, carpentry and cabinet-work, wood-carving, ivory-carving, watch-making, jewellers' work, and the machinist's and electrician's trades. In the bright little city of Zurich alone there are between eighty and ninety such schools, and Geneva is said to be, in proportion to the population, still more amply provided; while even in the villages, wherever, as is very much the case throughout Switzerland, small manufacturing is done at home, technical instruction is within easy reach of all. It is not many years since this movement began on a comprehensive scale in Switzerland, yet the silk scarfs and handkerchiefs of Zurich, the so-called "Hamburg" embroideries and laces of Appenzell and St. Gallen, the watches, music-boxes and jewelry of Geneva and Neuchâtel, the wood-carvings of Brienz, Meiringen and the Haslithal, and the electrical and other machinery of Winterthur, go all over the world, carrying with them the best possible evidence of the intelligence, industry and trained skill and taste of the Swiss. Notwithstanding the high intellectual capacity of the Americans, they cannot expect to maintain their place in the industrial world unless they soon follow the example of their rivals. No doubt, industrial organization on a great scale has reached a higher point in this country than in any other, but the education of the individual workman has lagged behind, and the great and increasing demand of the markets of the world for what may be called intelligent perfection of execution is not easily satisfied here. Notwithstanding the ingenuity, for example, of our machinery for carving, architects do not find it easy, outside of the great cities, where workmen trained in the foreign schools are available, to get even tolerable wood carving executed from drawings; and the system of training of American youth must be profoundly modified before there would be any possibility of getting from American farm-houses anything resembling the clever, and often beautiful, original wood-carvings which are turned out by the cord from Swiss cottages. Although all schools involve expense, and trade schools, on account of the cost of their equipment, are more expensive than others, they are, perhaps, the best of all investments, for not only do they make citizens capable of supporting themselves and their families, and a part of the public burden besides, in place of paupers, but they develop, by the superiority of workmanship which they foster, the market which is the necessary complement of industry.

PROFESSOR JAMES C. BAYLES is doing a good work in urging the construction of pipe-conduits by which gas and water pipes can be carried through New York where they can be inspected and kept in repair. It is not long since some startling figures were published, showing the leakage of water from the mains in New York; and Professor Bayles

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

shows that the leakage of gas is as wasteful of money, and at least as injurious to health, as that of water. During the year 1900, the leakage of gas from the mains of the Consolidated Gas Company amounted, as nearly as it could be estimated, to eleven per cent of twenty-four thousand million cubic feet, or in round numbers, three thousand million cubic feet. At fifty cents per thousand feet, the value of the gas so wasted in one year was a million and a half dollars, while the damage caused by explosions in sewers and cellars, to say nothing of illness and discomfort directly caused by the leakage, would amount to a large additional sum. With pipes running in conduits, the leakage, of both gas and water, ought to be easily stopped, to the immense advantage of taxpayers and householders. The expense of a proper conduit would not be very large, and, in connection with the Rapid Transit tunnel one could be very easily and cheaply constructed. New York, owing to the rocky subsoil of a large portion of the island, is a less favorable place for underground workings than Boston; but the interests involved are so important that something will undoubtedly be done in this direction before long.

THE electrical experts of the National Board of Fire Underwriters have issued an interesting report on the fire hazards due to electrical installations, giving many illustrations, from actual occurrences, of the ways in which electrical currents under high pressure may set fires or do harm at a considerable distance. In one case of the kind a piece of wire tied at one end to a tree in the yard of a house had fallen over an electric-light wire carrying three thousand volts. To the same tree was attached a rope, used for a swing. The owner of the house happened to grasp the swing-rope and was instantly killed by the current transmitted to it by the loose wire. In another case, where transformers were used to convert a high-tension primary current into low-tension secondary currents for distribution, a branch of a tree was burned off by a primary wire, and fell across both the primary and secondary wires, thus establishing a direct connection between the two. In consequence of this, the high-tension current, at twenty-three hundred volts, was sent directly into three houses, setting them all on fire. In these instances, of course, the owners of the houses could not have prevented the damage; but there are many cases where those who use electrical devices are grossly ignorant or careless in their handling of them. A clerk in a store had occasion to use an incandescent lamp attached to an extension cord. A thunderstorm was passing, and the service was temporarily interrupted. The clerk, finding that there was no current in the lamp, dropped it on a pile of dry-goods without turning the key. A little later the current was turned on, and the lamp set fire to the goods, causing a loss of thirty-five thousand dollars. The popular notion that there is no heat in an incandescent lamp seems to lead to many fires. In another case, a lamp attached to a flexible cord was left lying on a wooden seat, which was set on fire in consequence. As there is a strong tendency among electrical engineers to increase the pressure of primary currents, seven or eight thousand volts being now used with nearly as much freedom as a twelve-hundred-volt current was a few years ago, it is more necessary than ever for the public to use intelligence as well as caution.

THE Technical Commission, appointed to investigate the condition of the public buildings of the city of Venice, and take the necessary steps for meeting any dangerous conditions, has ordered the immediate demolition of the tower of San Stefano, which appeared likely to fall. The tower, which is a tall and slender one, was built about five hundred and fifty years ago, and the decay of the masonry, inevitable in a slender shaft exposed on four sides to the weather, probably accounts for its condition; and the same may perhaps be said of some of the lofty and ill-cared-for houses in the Ghetto, which have also been condemned as unsafe. The Cathedral of St. Mark, the oldest, next to the Campanile, of all the great public buildings of Venice, is pronounced to be in good order; and the Ducal Palace does not show any defects beyond those noticed two or three years ago, and attributed to the weight of the books in the great library, most of which were, in consequence, removed. Of the buildings around the Piazza, only the Procuratie Vecchie, on the north side, adjoining the clock-tower, was found to be in any danger. It does not appear that any movement had actually taken place, but calculation showed that the slender shafts of the arcade which occupies the lower story were overloaded by the weight of the mosaics, marble statuary and other heavy goods stored in the upper stories by the merchants who occupy the building, and all such articles have been ordered to be removed.

THE newspapers seem to view the announcement of the formation of a great real-estate and building corporation, with a capital of sixty million dollars, with mingled feelings. In New York, corporations formed to hold and manage real-estate are comparatively new, and it is not many years since New York brokers found amusement in the quotations of Boston stocks of real-estate companies. It is true that the history of some of the early real-estate corporations of Boston has not been financially brilliant; but a few have been very successful, and there is no reason why good judgment and careful and economical management should not be as effective in securing income from money invested in buildings and land as from railroad property. Whether stocks based on real-estate security will bear expansion like railroad stocks is doubtful. It is quite possible, in times of prosperity, for the managers of a railway to use all the profits of the road in paying dividends, and then, by issuing new stock or bonds, representing nothing but "earning power," to enrich themselves at the expense of the public; but with securities based on real estate this is not so easy. A story used to be current among brokers about the Coney Island Railroad, which paid its entire cost from the profits of one day's operation, but which, having gone through the process of "capitalization in proportion to earning power," went through bankruptcy not long afterwards. With real-estate such a catastrophe would hardly be possible. City property very well situated may, perhaps, bring in seven or eight per cent on the valuation, but rarely more, and usually much less, than this; so that "earning power" is not likely to serve as a basis for inflation; and, as the assessors' books are open to the public, any one can compare the total amount of stock and bonds with the valuation. With this precaution, people who have money to invest might do much worse than select good trust stocks in city real-estate. Except in times of wild inflation, the value of such real-estate tends slowly, but constantly, to advance. It may take a hundred years for it to double in value, but, even if it should, the increase is equivalent to an annual dividend, deferred, it is true, but none the less sure, of one per cent on the investment.

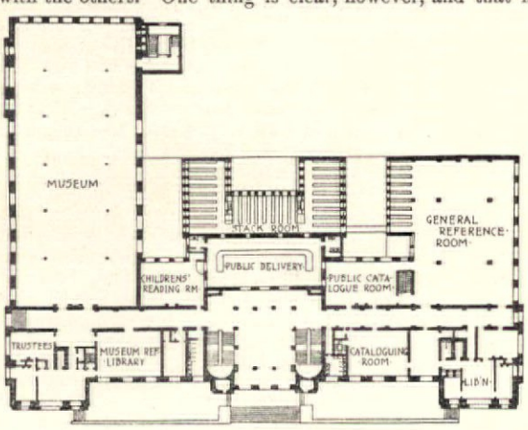
THE New York Rapid Transit Commission, which recently invited proposals for the construction of a submarine tunnel from the Battery, in Manhattan, to Atlantic Avenue, in Brooklyn, has received two offers. It was estimated by the Commission's engineers that the cost of such a tunnel would be about eight million dollars, and one of the bids received was exactly this sum. The other bid was from the Subway Construction Company, of which Mr. August Belmont is President, and proposed to do the same work for four million dollars. At the same time, Mr. Belmont made an informal offer to build a tunnel under Broadway, from Fourteenth Street to Forty-second Street, for one hundred thousand dollars. As the cost of a tunnel over this route, which is about a mile and a half long, would be about four million dollars, it is obvious that the corporation represented by Mr. Belmont is ready to invest a large sum of money in the two tunnels proposed, without return except such as can be derived from whatever control the Rapid Transit Commission may permit the builders to exercise over the tunnels after completion. It is generally believed that the Pennsylvania Railroad is interested in Mr. Belmont's company, and the fact that the proposed Forty-Second Street tunnel would carry passengers directly to the new station of the railroad gives some ground for the belief, although it is not very evident how the Pennsylvania road could profit much from a slight advantage in conveniences for bringing passengers to its station.

THE Cercle Littéraire Franco-Américain invites sculptors of all nations to submit models for a monument to be erected at Newport, R. I., in memory of Admiral de Ternay and the five thousand Frenchmen whom he brought with him to assist the Americans in their war of independence. The designs must be submitted on or before October 1 next. Details of the competition may be obtained by addressing the De Ternay Monument Committee, 138 West Thirty-fourth Street, New York.

LIBRARIES IN THE UNITED STATES.[1] — III.

TOWN LIBRARIES. — DIVISION I.

THE four buildings chosen to illustrate the planning of large town libraries are very unlike each other. In each case the motive of the design has been a different one. The first built, the one at Boston, is much larger than either of the others, and so is difficult to compare with the others. One thing is clear, however, and that is the



First Floor: Public Library, Milwaukee, Wis. Messrs. Ferry & Clas, Architects.

growth of the free-access policy and its great effect upon the plan. Not only is it necessary for the general reading-room to have, as in the Bates Hall at Boston, the walls shelved for books of reference, but the borrower must also be allowed shelves to select from; and the plan adopted at Newark of placing open-shelf rooms of ample area either side of the delivery-hall, where thousands of books may be stacked, is an excellent one. At Providence a different method is adopted. The shelves are placed between the entrance-hall and the delivery-space. This is not so good, the control being inadequate. The positions of the stack-rooms in three out of the four plans are in the rear of the main building. In Newark they are nearly isolated — a great advantage should fire occur in the main building.

The public-libraries at Chicago, Milwaukee [see plan above] and Jersey City are all particularly worthy of study if space permitted.

BOSTON LIBRARY.

The Boston Library [2] is, perhaps, the best known of all the American libraries. It was really the first great monumental one of the present library movement, and, architecturally, it is of very high merit, and its influence is much in evidence in many of the very recent ones. Its plan is not good from the librarian's point-of-view, but the librarians know now pretty well what is wanted, whereas, 15 years ago they were doubtful and uncertain, and library science has moved very rapidly, indeed, since, so that to-day obviously recent planning should be infinitely better than that done early in the movement. It was in 1887 that the trustees of the library decided upon the architects, and the building was started in November, 1888, but it was not until 1895 that it was opened to the public. The site is nearly square, and faces streets on three of the four sides. Its frontage is 225 feet and the depth 227 feet. The great central courtyard is a magnificent feature with its colonnade on the three sides, especially as seen from the half-landing of the great stairway leading to the main floor of the library.

In many ways the present plan varies from that originally settled upon and even built, rooms having been reallotted, and the delivery-hall quite rearranged. The building is placed on a raised platform, and the main entrance-hall is approached from three large arched openings in the centre of the principal façade. This first floor is occupied by the newspaper-room, 45′ x 81′, and two rooms for periodicals, each 34′ x 40′, all to the right of the entrance-hall. The newspaper-room has a row of five columns down its centre, and on the square bases of these, to a height of 4 feet 7 inches from the floor, are placed sloping newspaper-racks 2 feet 8 inches wide, four to each column; and also between them are placed upright stands 7 feet long, each capable of holding 28 newspapers, 14 on each side. Along the walls below the window-sills are the newspaper-desks. Altogether provision is made for 325 newspapers. Seven large tables are provided, each 12′ x 36′, seating 4 on each side. Chairs are also provided in rows of 6, placed back to back, thus largely increasing the seating accommodation. The room is lighted on two sides, the sills being 8 feet above the floor. The first periodical room is used as a reference-room, and in it are stored the recent numbers in cases along the walls and in a gallery around three sides of the room. It is seated for 32 readers at 4 tables. The other periodical room is used for the readers of current numbers, and in it more than 600 are displayed on cases placed against the walls, as well as in rests down the centres of the 6 tables. It is seated for 48 readers.

[1] A paper by Sidney K. Greenslade [*A.*], Pugin student, Grissell Medallist, Godwin Bursar, read before the Royal Institute of British Architects, Monday, March 17, 1902, and printed in the *Journal* of the Society. Continued from No. 1387, page 30.

[2] See plan, *Journal* R. I. B. A. Vol. VI, page 218.

Nearly the whole of the other rooms on this floor are used for administrative purposes. The catalogue and shelf department is 45′ x 81′, and adjoining is the receiving and ordering department. In the left-hand far corner of the building is placed the stack, returning half round two sides of the courtyard. It is the second floor of the stack at this level. In the opposite corner is placed the bindery, and adjacent to it the printing-department. There are besides rooms for newspaper-files, 32′ x 36′, and the branch department, 17′ x 68′ — both adjacent to the stack; also a reception-room, cloak-room, public telephone-room and public lavatories. In a mazzanine floor (level with the third floor of stack) are galleries around the periodical, reference, and newspaper rooms, connecting with periodical stack-room, 23′ x 34′, and in these galleries are cases with drawers in which are placed the current numbers of the periodicals before being bound. Ample luncheon and locker rooms are provided for the staff on this floor between the stack and the catalogue department. The newspaper-files room is also provided with galleries at this level. The stack at its third-floor level is of a greater area than either of the other floors. It is 36′ x 116′ one way and 40′ x 63′ the other; unfortunately at this floor-level it is inadequately lighted.

The great feature of the library is the reference reading-room, called the Bates Hall, which occupies the whole of the front on the second floor. Its two ends are apsidal and separated from the main central portion by screens, partially open, used as bookshelves. In the right-hand, or northern, apse are shelved the maps, dictionaries, encyclopædias, etc., and the southern one is used as the public card-catalogue room, which is also approached from the lending delivery-hall. The total length of the Bates Hall from end to end is 217′ x 40′ wide, and the crown of the barrel ceiling is 50 feet from the floor. It is lighted by 13 large semicircular-headed windows on the front and 2 at each of the ends, the sills being kept well above the bookshelves below them. It accommodates 264 readers at 33 tables. There are 2 rows of tables, each 10′ x 3′ 6″ and 30 inches high, provided with 8 chairs each.

Between each of the pilasters are fixed oak bookshelves 11 feet 9 inches wide, standing on a marble plinth 1 foot 3½ inches high; the height of the space for books is 5 feet, and the total height of case to top of cornice is 7 feet 9½ inches; horizontally they are divided into 3 divisions. In these cases around the room are placed about 8,000 books of reference. The attendant's desk is placed in the centre of the room opposite the main entrance; here books are changed and returned for use in the hall only. The books are brought from the stack on trucks with rubber-covered wheels.

The lending delivery-hall is to the right as one approaches from the main stairs. It is 33′ x 64′, and is fitted amply with chairs, tables, bulletin-boards, and shelves with recent books. Between this delivery-hall and the stack is the issue-department. The most noticeable feature here is the circle of pneumatic tubes to the left, through which the application slips are sent to all parts of the book-stack. An apparatus has been installed in the issue-department novel to library use. This is a "pick-up carrier." Its purpose is to transport the various slips between 4 points in the issue-department doing business with one another — the issue and return desks, the record-trays, and the pneumatic terminals.

At the stack-end of the issue-department are the book-elevators, and the book-carrier to these is a cable railway operated by electricity. Each story of the stack is equipped with an 8-inch track running its entire length. Each track has 3 stations, placed at convenient intervals, and each station has its own carriage — a low wire basket capable of containing all but the largest books. Girls are employed as "runners" on each floor to carry the books called for to the baskets. When the basket is loaded it is pushed from the station to the main track, where it grips the cable and is carried towards the issue department at the rate of 500 feet a minute. As the stack is in 6 stories, only one of which is on a level with the opening to the issue departments, 5 miniature elevators are provided — one for each of the stack stories above or below the level of the window. When the basket approaches it automatically slips the cable, and its speed having been gradually slackened it slides upon the elevator. If the elevator is "busy" the basket is held until its turn arrives. If it is not "busy" the shock releases a pin, and the motor below hoists or lowers it, as the case may be, to the window. The librarian's room with its private office is placed adjacent to the issue-department. The children's-rooms balance the issue-department on the north side; the larger is 34′ x 65′ and the other 37′ x 40′. The large room is fitted with 7 elliptical tables 7′ x 5′ and 2 feet 3 inches high, with 8 chairs around each. The shelving accommodation in the 2 rooms is for 8,000 volumes. In the small room are 6 tables 3 feet 6 inches wide by 12 feet long, with 12 chairs to each. From this room the lecture-hall, 40′ x 86′, can be reached. The patent-room, 36′ x 42′, adjoins the stack-room. The top, or third, floor is wholly arranged for special libraries. Alcoves — about 12 feet 6 inch centres — are placed around the whole of the outer walls. They have galleries around them with shelving. In each alcove is placed a table seating 8 readers, arranged next the windows which look into the courtyards, and altogether there are 29 alcoves. There is also a specially fitted room, 27′ x 51′, for music, and 2 rooms, each 35′ x 66′, one used for a special collection and the other as a fine-arts room.

It is a little unfair, perhaps, to criticise this plan, because of the rapid developments of library planning since its creation. Still, there are many points in it that are not good, particularly the position of the fine reference reading-room in relation to the stack-room

the cramped position of the delivery-hall, and the unfortunate shape and position of the stack-room, necessitating the use of elaborate mechanical arrangements for carrying the books.

The cost of the building was £473,000, and the shelving capacity at present is for 750,000 volumes. The architects were Messrs. McKim, Mead & White.

NEWARK PUBLIC LIBRARY.

The Public Library at Newark, N. J., was only completed and opened on March 14, 1901. It is evident that a deal of thought has been spent in its arrangement and planning. A great point has been made of "free access" to the books, both outside and inside the stack. The site is an open one with no curtailments. The main building has a frontage of 103 feet and a depth of 157 feet. Connecting this building to the 2 stacks in the rear is a small block about 30′ x 30′. Each stack-room is 60′ x 39′. At present only one is complete — the left one being only built at the basement level — and contains the engines, boilers, and the electric-plant. The general arrangement of the rooms on each floor is as follows: —

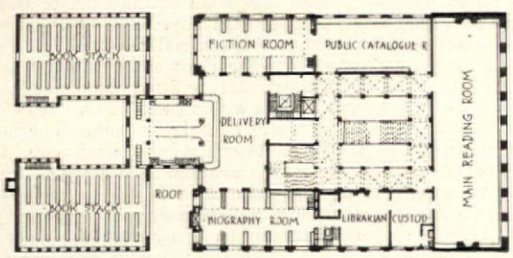
On the first floor are placed the newspaper reading-room, children's room, public bicycle check-room, public toilets, administrative rooms (including stock-room, binding, packing-room), delivery-station room, repair-room, and, to the rear, the stack-room and boiler-rooms.

On the main floor is the general reading-room, occupying the whole of the front of the building, as at Boston. The delivery-room is in the rear, opposite the landing of main stairs, and on either side of it are the 2 open-shelf rooms for fiction and biography. The delivery-room, with its counter and working space, occupies the connecting-block between the main building and the stack-rooms. The public catalogue-room and the librarian's public room are placed at the sides, between the general reading and the open-shelf rooms.

On the third floor are the reference-room, patents-room, art-book room, cataloguing-room, various staff-rooms, and 2 special study-rooms near the stack rooms.

The fourth floor consists of a lecture-room, the museum, and art-gallery.

The children's room, 29′ x 32′ and 23′ x 30′, is L-shaped in plan, and occupies the front corner of main building — easily accessible



Main Floor: Public Library, Newark, N. J. Messrs. Rankin & Kellogg, Architects.

from the street. Directly opposite the entrance is placed the attendants' enclosure, 16′ x 10′, with counter all around, 2 feet 1 inch wide and 2 feet 6 inches high, fitted inside with shelves and with a gate at the back. In the space between the entrance and counter, divisions are placed to direct the ingoing and outgoing readers. The ways are 1 foot 3½ inches clear. It does not answer well, as the division is not carried to the floor, and children slip out. There are 6 tables, 3′ x 5′ x 2′ 4″ high, seating 10 readers each — decidedly too many to a table. In the portion of room directly to the left of the entrance 2 steel stacks are placed, 1 foot 4½ inches wide and 9 feet long, and of the same height (5 feet 2 inches) as the steel shelving placed all around the walls of the room. These isolated stacks form small alcoves, which are used as the reference portions of the room. The shelving capacity of the room is for 8,000 volumes.

The newspaper reading-room occupies an exactly similar position as the children's room to the right. It can be approached either from the main entrance or the side. Adjoining it is the men's lavatory. The binding and repair rooms are placed adjoining in the left-hand far corner next stack-room, one being 24′ x 38′ and the other 19′ x 20′. The delivery-station room, 28′ x 30′, is placed between the stack-rooms and the main building. From this room small lifts run to all the floors of stack. The floor of this room is some feet above the level of the road outside, so that when the delivery-wagon backs up the cases of books for the stations can easily be shifted onto it. The sizes of the boxes for the books are 1′ x 1′ x 3′ 3″. In the centre of the room is a long table, 2 feet wide and 3 feet high, with cork-linoleum top, for taking these boxes; and, adjoining, a table, 12′ x 3′, with 3 tapered divisions 15 inches high, with table-top 2 feet 9 inches from floor, in which the books for the separate boxes are checked and dispatched. The first floor of stack-rooms is level with this floor of main building.

Ascending the main staircase to the second floor, one enters through a short corridor directly into the delivery-room, which is 28 feet 6 inches deep by 48 feet wide. The open-shelf rooms on either side, each 24′ x 51′, are fitted with steel stacks for books of fiction and biography. To get to these rooms the reader has to pass through one of the turnstiles in the delivery-counter, which is divided into 3 — the central portion is 18 feet 6 inches wide, and the other counters for changing and registration on either side are each 7 feet 6 inches, and between are the turnstiles for entering and leaving. There are 2 turnstiles to each opening, each 15 inches wide. This counter necessitates 3 attendants at least — sometimes 4. The openings between the columns to these rooms have large fixed seats between them, so preventing access from the delivery-room to the books without passing the turnstiles. The steel stacks in them are somewhat differently arranged from that shown on the plan. There is only 1 row to each room: they are 12 feet long and 8 feet 6 inches apart, and are placed 18 inches from the wall, so there is ample room for the circulation of readers choosing books. A gallery with a glass floor is fixed over, so that another floor of stacks may be erected when necessary. Between the delivery-counter and the stack-room is the delivery working space, 28′ x 36′. In the 2 enclosed spaces either side of gangway leading to the stack-rooms a great deal of the work of the library is done. Rather inconveniently placed in relation to the delivery-room is the public catalogue-room. It is 23′ x 51′, and in it the card catalogue is arranged in desks around the room and down its centre, instead of in the usual upright stands with small drawers: it therefore necessitates a great deal of space for its display.

The main reading-room is placed to the front and occupies the whole width of the building; it is 29′ x 95′. It is entered from the gallery around the well of the entrance-hall at 2 points. Like the Bates reading-room at the Boston Library, it is lighted from the front by a series of large windows. The room is oak-panelled to the height of the window-sills, which is 8 feet. The dado-moulding is 3 feet 10½ inches high, and between the bays above this moulding are placed vertical cases for the periodicals, 1 foot 6 inches high. There is no book-shelving. It is fitted with 15 tables, each 3′ 4″ x 9′ 9″, placed in 2 rows, and with 9 armchairs to each, and 1 round table 6 feet diameter, accommodating 140 readers altogether. The attendant's desk is placed next the public check-room. The height of the rooms of this second floor is 20 feet.

The reference-rooms on the third floor are particularly well arranged. The assistant's desk is placed just opposite the entrance, and all readers have to pass it, the doors which originally opened from the patents-room and art-book room to the gallery surrounding the staircase-well having been closed. The top floor of the stack is level with this floor, and is quite open to it and reserved for reference-books. A locked gate is placed at the stairs, so that the lower portions of the stack-rooms cannot be reached. Three special study-rooms, 10′ x 13′, are placed adjacent over the working-space on the floor below.

The reference-room consists of 2 rooms 24′ x 56′ and 28′ 6″ x 50′. They are both divided into alcoves by steel stacks, which are 7 feet high and 9 feet long, placed at 10 feet centres; in each alcove is a table 2′ 3″ x 3′, with seats for 4 readers.

In the patents-room (23′ x 51′)the stacks, which are 21 inches wide by 6 feet long, are arranged in a similar manner, but against the inner wall, and the 4 tables, each 5′ x 3′ 3″, accommodating 16 readers altogether, are placed at the piers between the windows. Through the patents-room, the art-room, 29′ x 42′, is reached. Here 2 large leather-covered and padded rests for large books are placed in the centre of the room, 3′ 4½″ x 5′ 3″ wide and 7 feet 6 inches long, divided into 3 divisions on each side. The front portion of the room is divided into 4 alcoves by wider stacks than used in the other rooms, the lower portion of each being 4 feet wide by 3 feet high, and the upper portion 2 feet wide by 4 feet high.

The stack-room is shelved to take 33,600 volumes on each floor, and there are six floors, the first being level with the first floor, the third with main floor, and the sixth with reference-floor, providing a total shelving-capacity for over 200,000 volumes. The stacks are 12 feet long, divided by a centre passage-way 4 feet wide, with side passage-ways 3 feet wide. The uprights are of steel, the shaped ends and rests for shelves are of copper, the shelves are of wood, and the floors of glass. A lavatory-basin is placed at the end of each central gangway, and at each corner of the stack-room on each floor dust-flues are provided. They are 12″ x 12″, with galvanized-iron shutters; the flue is covered with wire-netting to prevent books from falling, and the particles of dust are sucked down out of the building by fans.

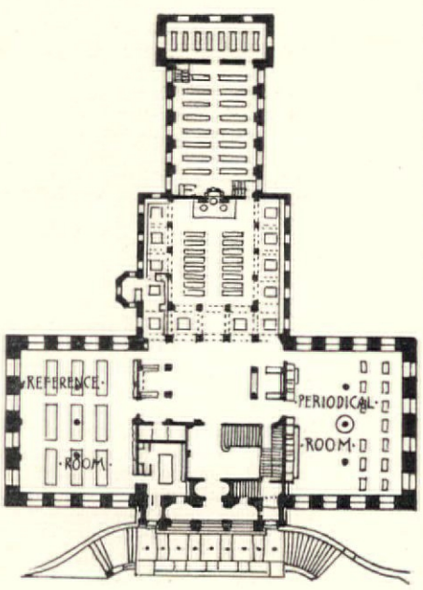
All the windows of the stack-room are fixed, to prevent dust getting in, and on the outside for cleaning purposes 2 iron galleries are placed at the third and fifth stories; the windows placed between each row of stacks have their sills only 12 inches from the floor, so well lighting the bottom shelves of books. On each floor of the stack-room is a telephone, and automatic-electric book-lifts are placed just outside, in a gallery overlooking and open to the working delivery-space. Its position here is necessary, for when the second stack-room is built the lifts will be common to both stacks.

The upper floor does not call for comment. There are some excellent points in the planning of this building. The arrangements for the open-shelf rooms, delivery-hall, work delivery-space and stack-rooms are very good indeed, and the approach to these rooms from the main entrance is very direct. The cost of the building was £60,000, and it was designed by Messrs. Rankin & Kellogg, of Philadelphia.

PROVIDENCE PUBLIC LIBRARY BUILDING.

The Public Library Building, Providence, R. I., was completed and occupied in March, 1900. A competition limited to the architects of Providence resulted in Professor W. R. Ware selecting the plans of

Messrs. Stone, Carpenter & Willson. Owing to successive liberal gifts these were much modified and enlarged, and it was not until 1896 that building-operations were commenced. The site is quite isolated and nearly 200 feet square. The building itself, consisting of the main block, 139′ x 58′, and the stack-building at the back, 108 feet long and of varying widths, covers an area of more than 11,600 square feet. The boiler-house is placed outside the building in the rear to the right. In the planning of the Providence Library it is evident that the librarian's point-of-view was well considered, and his advice invited in the attempt to solve a problem which had not been altogether successfully coped with. The Providence plan is, therefore, an interesting one, coming, as it does, between the Boston and Newark libraries in date.



First Floor: Public Library, Providence, R. I. Messrs. Stone, Carpenter & Willson, Architects.

The basement, which, owing to the fall of the ground from front to rear, is particularly well lighted, contains more stack-room accommodation than any of the floors above, the whole of the space below the delivery-room being occupied. The men's staff-room, fitted with steel lockers and with lavatories adjoining, men's and women's public lavatories, packing-room, supply-room, bindery, are all arranged in the front block. In the rear to the right is a bicycle-yard 25′ x 34′, fitted up on each side with holders, with an entrance to the building and to the back streets.

The first floor includes the 3 rooms which every visitor needs to find directly accessible to him, the delivery-room (80′ x 50′), in immediate contact with the stack and the 2 main reading-rooms; the periodical-room (41′ x 50′); and the reference-room (41′ x 50′), with small map-room (16′ x 12′). These 3 rooms together comprise an area of more than 7,800 square feet.

On the second floor are placed the lecture-hall, 37′ 4″ x 40′ 10″ (seating capacity 110 persons), the children's department occupying 2 interconnecting rooms, one 24′ 6″ x 40′ 10″ and the other 18′ 3″ x 18′ 10″. The standard library is a feature of this library; it has 2 interconnecting rooms (one 12′ x 39′, and the other 19′ 6″ x 20′). There are also 4 interconnecting administrative-rooms for the librarian, the auditor, records and trustees. All these are in the main building. Behind, over the delivery-room, is a large educational study-room, 27′ 6″ x 36′, and beyond is the fourth stack story, 27′ 6″ x 43′ 10″, with the women's staff-room, 12′ x 20′, and their toilet-room adjoining.

The third story is preëminently "the special-library floor," providing laboratory facilities in connection with works on art, industrial literature and other departments which are necessary for a manufacturing centre. There are 2 reading-rooms, the industrial 16′ x 18′, and the medical 16′ x 27′ 6″, with their stack-rooms for patent literature and medical literature, each 21′ 4″ x 39′, adjoining. There is also a room 58′ x 43′ 6″ divided into alcoves for special libraries on art, music (including a collection of musical scores for circulation), historical collections, etc. The whole of these rooms are top-lighted, which is unfortunate, the heat in the summer months being very great indeed. This third floor is connected with the sixth floor of stack, which is also top-lighted here, and beyond the stack are placed 2 study-rooms over the 2 below on the fifth floor of stack. Two of these study-rooms are 12′ 6″ x 15′, and 2 12′ 6″ x 18′ 10″. The stack building (the central one of 3 to be erected at some time in the future) contains besides the stack and the 4 study-rooms at the back, etc., already described, the greater portion of the delivery-room, 48′ x 48′, which projects into this part of the building, so that an important point is thereby secured — the delivery-counter is placed in an ideally favorable position, with stack above and stack below as well as stack beyond. In what is really the inner main hall are the registration-desk and information-office, and between this hall and the delivery-room beyond are placed, between the piers, the cases containing the new books and books of interest on special subjects engaging the public attention at the time. The delivery-space proper is 27 feet 6 inches wide by 36 feet long, and is fitted with seating on each side similar to that shown on plan. Beyond is the delivery-counter, about 14 feet wide and projecting 5 feet from the wall; there is room for 3 attendants behind it, 2 at the counter and one behind in the recess at the opening connecting with stack-rooms. Here is placed a shelf, and books are delivered direct from second and third floors. From the first, fourth, fifth, and sixth floors, small elevators are used. The level of the second floor of stack above delivery-room floor is 3 feet 7 inches.

The ceiling to the two wings and to the two side approaches to the delivery-room being much lower than those over the other portions, light is obtained over them, so ranges of lunette-openings are possible by this means on three sides. Besides small windows, the wings also have skylights in each bay (see plan). In the right wing are placed the shelf-lists, which are type-written and bound, and in the left wing the card-catalogue, where a large table is provided as well as a shelf-ledge all around the walls for standing to.

The cataloguing-room is really cut out of the delivery-room, and no doubt when an enlargement of the library takes place more room will be provided for it; its bay for small reference library for official use is a pleasing feature.

The reference-room (41′ x 50′ and 16 feet 4 inches high) is well lighted on its three sides, the sills of the windows being above shelves round the room: these are 5 feet 3 inches high. Those to wall in which entrance occurs are 7 feet high. It is fitted with 6 tables, 12 feet long and 3 feet 6 inches wide, seating 5 readers either side, a total of 90 readers. The attendant's desk is placed in the right-hand corner next cataloguing-room. The small map-room off this room is conveniently situated.

The periodical-room, of the same dimensions as the reference-room, differs in arrangement from it. The far portion of the room is fitted with 2 rows of 6 small tables, 2′ x 4′, with 4 chairs to each; one large table is reserved for women. The room is shelved in a similar way to the reference-room. The inner wall is fitted with cases containing drawers for the current numbers of periodicals, where they are kept previous to binding. In the centre of the room, arranged around a column, is placed a periodical-stand containing spaces for just 200. The lower portion to a height of 4 feet is circular, the remainder being octagonal. At a height of 3 feet 2½ inches it has a 12-inch sloping rest. The lower portion has 12 divisions in its height, the first being 7½ inches off floor, and the upper portion 15 divisions and is 2 feet 7½ inches high.

The stack-room at this level consists of a front portion 27 feet 6 inches wide by 43 feet 10 inches long, and the end building placed longwise to it 12′ 6″ x 34′ 6″. Each floor of the stack is 7 feet 1 inch from floor to floor. The whole of the fittings of the stack are of steel, including the shelving. The gangways are of glass, 2 feet wide, with a 3-inch air-space each side between glass and shelf-line, making space between shelves 2 feet 6 inches. The width of each stack is 1 foot 10 inches and the ends are solid. The shelves are of steel, rounded front and back, enamelled, and are 10 inches wide. The walls are lined with 1-inch polished white marble, in slabs of one height, 6 feet 7 inches and 2 feet 10 inches wide. The 6-inch skirting is of polished black marble. The stacks are very well arranged, well-lighted, and not over-crowded, the only ill-lighted portion being the central space of the room below the delivery-hall.

A special provision has been made for dusting books. On every stack-floor a small closet is arranged for this purpose at one end, and all dust shaken from them into a hopper is drawn by a 1½-horse-power fan, placed just below the roof and discharging the dust-laden air by a 6-inch pipe passing through it. There are 2 staircases between the floors of stacks, one at each end.

The room set apart for the standard library is a well-proportioned room with a barrel ceiling. It has fixed seating on two sides, and book-shelves to a height of 5 feet 3 inches on the other sides. The assistant-librarian's desk is placed in this room and several small tables 1 foot 8 inches high and 18 inches diameter are arranged near the seating. The special reading-room adjoining is 18′ 6″ x 20′, also fitted with shelving.

The children's room (24′ 6″ x 40′ 10″) is fitted with tables to accommodate 48 readers, 3 each 3′ 6″ x 9′ 9″ for 8 readers, and 2 each 3′ x 12′ long for 12 readers; these long tables are only 2 feet high. The attendant's desk is at the entrance, and a small work-table is placed in the centre of the room. The central column has framed around it panels for exhibiting pictures. Shelving is placed around the walls, 4 feet high to window-sills, and one shelf higher between them. The card-catalogue is placed in the far corner of the room, with table for reference. The adjoining room is used as a class-room for the study of special subjects. Cupboards to a height of 3 feet with a 12-inch ledge are arranged around the walls, and above to a total height of 7 feet the walls are covered with colored linen, having brass rods to which photographs and drawings may be hung. The first rod is 1 foot 5 inches high, then 12 inches, then 6 inches and 6 inches, 4 rods altogether. The room has one large table, 4′ x 9′, with 8 stools to it. Off this room is a small lavatory with basin only; other toilet accommodation is provided in the basement.

The cost was about £53,000, and the shelving capacity is for 225,000 volumes. Generally this is a very interesting building. A serious attempt has been made to meet the new requirements of the "free access" policy, and to a large extent it has been successful.

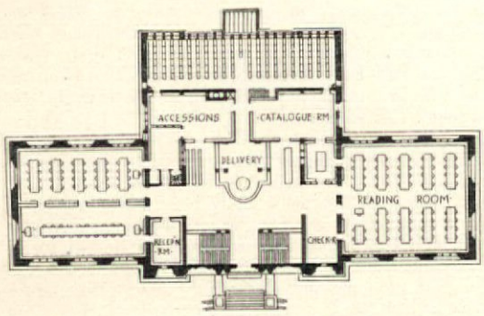
WASHINGTON PUBLIC LIBRARY, WASHINGTON, D. C.

The design for the Washington Public Library Building, Washington, D. C., was the result of practically an open competition. Ten well-known library architects were invited to compete, each receiving a honorarium of £50. Other architects were also allowed to send in schemes, and the result was that the plans of Messrs. Ackerman & Ross, of New York (not an invited firm), were selected. The programme of the competition was issued in May, 1899, and in August, 1900, building-operations commenced, after the plans had

been very much revised. The conditions of the competition were very carefully drawn up, and the cost was limited to £50,000, but this was overstepped considerably, the total estimated cost being £70,000. Altogether the building covers over 17,000 square feet. Its frontage is 220 feet, with 60 feet return ends, and the greatest depth through centre is 111 feet 6 inches where the stack-room occurs. The building consists of basement and 2 floors above. The basement (12 feet floor to floor) is but partly below the ground-level and is well lighted. The entrance to it is placed under the approach of the main entrance above, the vestibule being 20′ x 15′, from which the stairs on either side lead to the main vestibule above. Entered from half-landings, placed 6 steps up, is arranged the lavatory accommodation for men and women, the latter to the right and the former to the left. Beyond the vestibule is a large space for bicycles. One room only — that occupying the west wing — is intended for real library use; it is 58′ 6″ x 50′, and will ultimately become the children's reading-room when the demand for juvenile accommodation outgrows the space provided on the first floor for this purpose, or when the children's room on the first floor is needed for the open-shelf accommodation. The east wing, of the same dimensions, is devoted to the staff lunch-room (20′ x 24′), fitted with lockers, with a kitchen and pantry adjacent, store-rooms, and rooms for the caretaker, house-cleaners, and scrub-women. The boiler-room (52′ 6″ x 32′) extends down to a sub-basement (21 feet 6 inches) below the first-floor level, therefore 9 feet 6 inches below the basement floor, and is placed right in the centre of the building. Behind it are placed the packing and delivery room (34′ x 22′) and the station-delivery (15′ x 25′), into which delivery-wagons can back, having a staircase and lift to the stack-room. The room for binding and repairs (34′ x 22′) occupies the other corner. Near it is the attendants' entrance.

The first-floor entrance is approached by a wide flight of 16 steps. From the vestibule the delivery-hall is entered, and directly opposite the entrance is placed the delivery-counter. Not including the staircases either side of the vestibule, the space devoted to the public and the officials for delivery-work is about 50′ x 40′.

The delivery-counter has a frontage of 60 feet to the delivery-hall and the card-catalogue is placed to the right, and seats for the waiting borrowers to the left. At the back of the counter (beyond the



First Floor: Public Library, Washington, D. C. Messrs. Ackerman & Ross, Architects.

corridor) is the stack-room, which is 22′ 6″ x 83′, occupying the whole north end of the central block and extending up through both first and second stories, containing altogether 5 floors of 7 feet each in height, and having a shelving capacity of about 264 500 volumes. There are altogether 21 rows of stacks, 18 feet long on each floor, with light between each row, and the upper story is top-lighted. The floors are to be of white marble or glass.

On the west side of the corridor leading to the stack-room the accession-room and librarian's room are placed, while on the east side the catalogue-room and small reference-room occupy similar positions.

In the east wing is the general reading-room (58′ 6″ x 50′), arranged with 9 tables seating 8 readers each, and one seating 4, also an attendant's desk. Around the whole of the walls of the room shelves are provided to a height of 5 feet, which will contain 7,770 books. This room is exceptionally well lighted on three sides by 8 fine windows.

At present the west wing, of similar dimensions, is divided into two by a temporary partition, half arranged as the children's room, with 5 tables seating 8 each, with shelving around for 5,500 books, and the other half arranged as an open-shelf room, also shelved for 5,500, with one long central table seating 20 readers. In time, as before stated, the whole of this wing will be devoted to the open-shelf room, and the children will occupy the large room below it. The other rooms to be noted on this floor are the check-room and reception-room, on either side of the staircases and adjacent to the entrance.

On the second floor is the memorial hall (50′ x 25′) placed centrally to the front. To the right, over the reading-room below, is the newspaper and periodical room, of the same dimensions, and fitted similarly; to the left the lecture-hall occupies a similar position. Four special study-rooms, each 20′ x 14′, are placed conveniently near the stack-room.

[To be continued.]

NOTES ON THE LATE PARIS SALONS.

IT is sad to think of our loss in the death of M. Benjamin-Constant. Without doubt the best portraits in the *Salons* are his work; and now, as regards this our world, he has gone down into silence. But as a lady *en passant* remarked, "he has not been fortunate in his models"; nevertheless he has turned out a grand portrait in his "Lord ——," and if M. Blowitz's is not that of an Apollo or of a fine gentleman it is not the painter's fault. It is instinct with life. It is curious to note the departure in Constant's work from the old manner of a thick *impasto*, and the adoption of a more broken up handling. His coloring too has altered since the days of "Theodora," and for the better.

It will save trouble in writing these notes and in reading them if I put the initials S. for the old *Salon* and B. A. for the new.

So many artists at the latter seem to have fallen off, but a few keep up their reputations. Mr. Harrison (B. A.) has exquisite moonlight and sunset effects of water and sky — iridiscent shimmering, purple-green sea flowing in over a flat sandy shore. M. Lerolle's "Bergère" is charming, though he has left that beautiful gray, silvery tone of his "S. Geneviève." Noteworthy too are M. Dagnan's (B. A.) "Bretonne" and portrait of an elderly lady — they are refreshing simplicities perfectly rendered and of a far higher standard and purer style than the large pictures we have seen of late with accessories of red curtains and electricity. M. Detaille (S.) has achieved a great success in his two large decorations for the Paris Hôtel de Ville, especially the "Reception by the Municipality of the Troops returned from Poland" in 1807. It is full of curious uniforms and costumes, singing-ladies and harpists, which, with the obsequious Minister stepping forward to decorate an "eagle," form a spirited picture of that time of enthusiasm for all things military. Both pictures are instinct with life and beautiful in color; may their fate not be that of M. Clairin's in the Halles au Blé or of poor Baudry's at the Opéra — practical destruction. It is a satire upon conscientiousness that Baudry, thinking it honest and just to put of his best into the Opéra pictures, would not ease the work by having help; not only was his health ruined, but his other work was but little, for want of time. And now? His devotion is rewarded by blackened pictures which may justly make people ask why he had so great a reputation? But that his contemporaries were right is proved by the few masterpieces of portraiture which remain. Does it not seem a folly to commission great artists to decorate buildings and then let gas and smoke destroy their work? The Beaux Arts is best in its decorative-art department, jewelry (by such a master as M. Boutet de Monvel!), glass and faïence, and we may see as a fact that it is not moonshine to assert that, given the public to buy expressive artistic nothings, there is no fear of the production of such work failing — labor is expensive in these days, and artistic work is slow, but genuine artists exist. M. Maignan's Eve called "Seduction" (S.), is a new, or rather a revived, reading of the old subject, for I remember once seeing a thirteenth-century MS. with a similar serpent standing up on his long, coiled-up tail. That such painters as MM. Olive, Montenard, Allan Hitchcock and Matignon and Damoye should be interesting need scarcely be stated, but we miss so many whom we look for with great expectation, for instance, M. Jean Béraud is absent, and M. de Richemont is only represented by a small "Matérnite" (S.), charming as far as it goes, and M. Carrière, by some studies in monochrome. They are therefore disappointing shows. M. Aimé Moreau has hit upon a new subject: some blacks carrying a dead lioness (or lion) through the jungle to a canoe, called "Au Tableau" (B. A.). It is a powerful work and excellent in tone.

Another decorative panel (for the new Sorbonne) "Un Cours de theologie: — les étudiants au XIV^e^ Siècle," is very strong in color; and like the same artist's work at the Opéra Comique, exceedingly picturesque. Remembering that Dante sang his "*Divine Comedy*" to the students in the precincts of the old University over against the ancient church of S. Julien-le-pauvre, one imagines from the likeness to the poet at Florence, that he was the reciter — but if so, why *theologie*?

Taking the two exhibitions *en masse*, we must admit that they are dull and vastly inferior to those of former years; and it is a question whether the London R. A. show is not in many ways superior.

S. Beale.

ELECTRICITY A MATERIAL SUBSTANCE.

THE generation of "electricity" consists in splitting off an electron from the atom. The electron then produces a stress in the ether similar to that due to a "negatively" charged body. The remainder of the atom acts as a "positively" charged body, though we do not know as yet whether the positive charge is due to a special positive electron or not. If it is, we have not yet succeeded in isolating the positive electron, but it is supposed to be about ten times heavier than the negative electron. In any case we have here an elementary negative charge of about one ten-billionth of the absolute unit and an elementary positive charge of the same amount. These elementary charges attract each other and repel similar charges. They can associate with clusters of neutral particles. A negative electron thus associated with ordinary matters becomes a "negative ion," and a positive electron becomes a "positive ion." Conduction consists in the wandering of positive ions down the potential gradient, and of negative ions up the potential gradient.

This wandering can take place in metals. It then produces heat by collision with the molecules of the metal, and a magnetic field by the motion of the charges. In a liquid, the energy of motion is consumed in the splitting up, or "ionization," of neutral molecules. Every current of heat is associated with a transportation of ions, and here the whole field of thermo-electricity is entered. In the vacuum-tube, ions move with less restraint. Negative electrons are shot off from the cathode with the velocity of light, or something very nearly approaching it, and where they strike upon a solid they produce explosive ether-waves of remarkable penetrating power which are known as Roentgen rays. Where they hit gaseous particles they ionize them, and in doing so develop great heat and light, thus giving rise to the whole fascinating vista of vacuum discharges.

Nor is their wonderful activity confined to the fields enumerated, for the whole phenomena of magnetism are based upon the electron. Whenever an atom has a high valency, such as iron, cobalt, or nickel, it appears that the free electrons which constitute these valencies revolve around the rest of the atom. These revolutions produce whirls in the ether which are known as magnetic displacements or stresses, or "lines of force," and whenever a "conductor," *i. e.*, a body containing freely movable ions (say one for every five thousand neutral atoms) is moved through these whirls, the ions are set moving in opposite directions with a velocity of about one centimetre per second, and we have the whole phenomena of induced currents.

The enormous rapidity of the magnetic revolutions may be judged from their probable period, which is about one-trillionth of a second. In the electric arc we have not only a great exchange of opposite ions, but this ionizing action of ultra-violet light — and Elster and Geitel have shown how this ionization action of ultra-violet light may lead to the elucidation of all the problems of atmospheric electricity. The latest information, as recently supplied by us, goes to show that ionization is constantly going on wherever there is matter, and that some bodies have the faculty of projecting either negative electrons or positive ions with some force. These bodies, like radium, actinium and polonium, are then said to be radioactive. Hurmuzescu has gone farther, and proved that the electrons revolving in magnets often shoot off at a tangent and "electrify" a liquid in which they are placed.

All these manifold applications of the electron idea show that we have here one of the most fruitful conceptions of the human mind. We have at last discovered, and even isolated, what we may call the "electric substance." We can weigh it and measure it and produce it in any quantity. It may yet prove to be the "protyle" of the philosophers; the fundamental and primordial substance of the universe. Whether it is that or not we have now some definite and almost tangible nucleus around which to crystallize our thoughts. The "electric charge" is now no longer a mere phantasm of the mathematician. It is a solid reality; as solid, at least, as a deal table. It remains . . . to remodel our text-books in accordance with the new truths, and to build up our whole electrical science upon the properties of the substance whose conquest has been so long and arduous a task. — *London Electrician.*

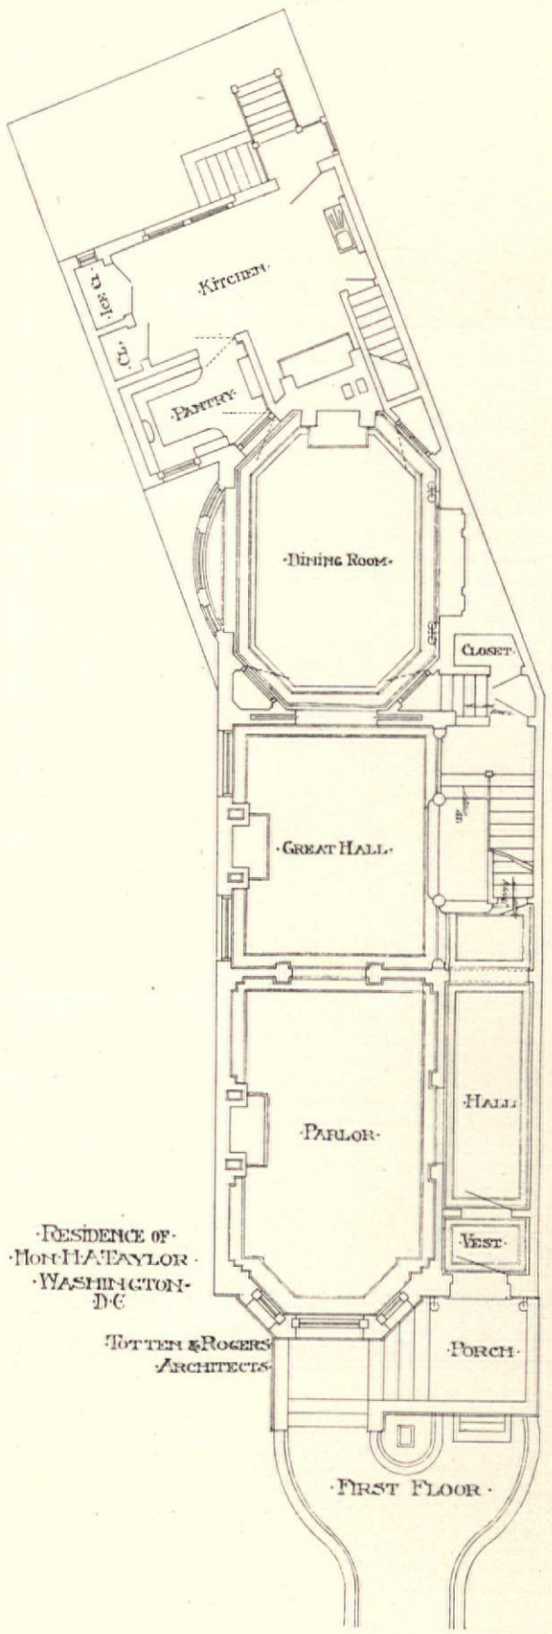
A HOUSE AT BAR HARBOR, ME. MR. A. W. LONGFELLOW, ARCHITECT, BOSTON, MASS.

HOUSE OF HON. H. A. TAYLOR, WASHINGTON, D. C. MESSRS. TOTTEN & ROGERS, ARCHITECTS, WASHINGTON, D. C.

THIS house was built for the Hon. H. A. Taylor, Assistant Secretary of the Treasury. It is located on the north side of Massachusetts Ave., west of 20th St., and was designed by Totten & Rogers, architects. It is somewhat in the style of the early Italian Renaissance. The façade is of Indiana limestone, with the upper



panels of red Vermont marble, the cornice of copper and the roof, tile.

The lot upon which the house stands is quite irregular, but this is overcome in the plan, so that one does not notice any irregularity in the interior. The first story consists of a reception-room, central hall, dining-room, butler's pantry and kitchen. The reception-room is treated with pilasters and a richly-decorated cornice, all white,

while the body of the walls is pink; the effect is very rich. This room is unique, inasmuch as the side-walls do not extend to the ceiling, thus giving vistas into the adjacent rooms. The staircase ascends from the central hall, which is partly screened by three arches; the treatment of this room is mahogany.

The dining-room is an irregular octagon in shape. This room, too, is largely of wood — oak, of rich dark antique finish. As the Secretary has a rare collection of Indian vases, heavy shelves, supported by pilasters, are placed over each door, forming a sort of plate-rail. The elaborately carved fireplace at the end of the room forms the terminating vista of this floor. The side-walls are lined with burlap, hand-stencilled.

MANTELS, ETC., IN THE SAME HOUSE.

LIBRARY ARCHITECTURE.

MADISON, WIS.

To the Editors of the American Architect:—

Dear Sirs, — A meeting of librarians, trustees and all others of the West and Middle West interested in library work will be held at the State Historical Library Building, at Madison, Wis., on Thursday, Friday and Saturday, August 28, 29 and 30, next.

Saturday afternoon, August 30, will be exclusively devoted to the subject of "Library Architecture." Architects are cordially invited to make exhibits and to attend this meeting, that a full discussion may be had between librarians and architects on the principles which should govern library architecture. This is the first time in the history of the library movement of the West that a full session at a meeting has been devoted to this subject, and it is earnestly hoped that many architects will avail themselves of the opportunity to meet librarians for interchange of opinion on the date mentioned.

Further particulars may be obtained by addressing

[Miss] L. E. Stearns.

A CORRECTION DENIED.

BOSTON, MASS., July 24, 1902.

To the Editors of the American Architect:—

Dear Sirs, — In the July number of *The Ladies' Home Journal* — as the third prize for $5,000 country houses — was published a photograph of a house designed and superintended by me, stating that the house was from plans by the owner.

I courteously called the attention of the *Journal* to the facts in the case, and after some correspondence, offered to send them a sworn statement from the builder and from persons in my office who saw the sketches and plans prepared there, to all of which they return answer that they decline to make any correction.

If you would care to express an opinion on what to me seems such a piece of high-handed injustice, it would give me great satisfaction.

Very truly yours, G. Walter Capen.

[There is nothing more curious in life than the discovering just what other people consider decent behavior. — Eds. American Architect.]

NOTES AND CLIPPINGS

German Artificial Clay. — Artificial clay, according to recent German reports, is receiving increased attention abroad. This ceramic novelty, which is used for the manufacture of artificial stone, tiles, gutters, etc., is composed of sand, chalk, cement, liquid-glue, and petroleum. The substances are mixed in certain quantities, and a clay-like mass results, which can be formed at pleasure, and acquires an excellent degree of hardness by being subjected to heat. The artificial clay can be employed in a variety of structures; tiles of different form and sizes are made of it. They have a perfectly even surface and sharp edges, are fireproof, and resist the influence of the weather; they furthermore absorb no moisture. The clay is also used for the manufacture of artificial stone in all colors. Tests with this clay have been made at the Technical Experimental Station at Charlottenburg, and the results have been pronounced very favorable. As the substances are easily mixed without the aid of machinery, the United States Consul at Frankfort says that the smallest builders can use the process, and so obtain structural decorations at a low price. — *Journal of the Society of Arts.*

Roman Villas. — There was no limit in the size and no regularity in the construction of a Roman villa. The opulent patrician indulged in many, spread over the fairest districts of Italy, in situations either adapted to the changes of the season and to the taste of the owner, or dictated by his caprice and the fashion of the times. The arcaded substruction of numerous ancient villas still remains, while the buildings above are in ruins, either by the depredations of those who in after ages demolished to erect other buildings, or by the silent waste of time on such as were erected of the soft tufa. On many of the Roman villas convents and monasteries were erected, as materials were at hand, and the arcades of the substructions formed conveniently storehouses and cellars. How long the Roman villas remained habitable after the many invasions of Italy is not easy to ascertain. One of the celebrated villas of Lucullus, formerly belonging to Marius, and afterwards an imperial residence of Tiberius, situated on the promontory of Misenum (Capo Miseno), existed in the year 480. To this retreat was sent, by the clemency of Odoacer, King of the Heruli Goths, the last feeble representative of the Roman Emperors of the West, called in derision Augustulus. The villa had gradually been changed into a strong castle to protect it against the sea attacks of the Vandals. These invasions by sea of the Vandals, and subsequently of the Normans and Saracens, ruined probably the crowd of Roman villas on the Neapolitan shores. The villas on the fertile plains of Italy would suffer by the invasions by land; but many villa castles, or fortified residences, remained after the tenth century in the hilly districts of the Vicentine and Veronese territories, as their rural nobility descended into the cities of Padua, Verona, Vicenza and Trevisa, and took part with the Guelph faction. In the thirteenth century 150 castles were computed to be in the Milanese. It was probably to a Roman villa that Avitus, lieutenant of the Emperor Maximus, and afterwards himself a short-lived emperor, retired in the year 460. It was situated near Clermont, in Auvergne, on the margin of a lake, into which rushed a mountain torrent of cascades. The villa contained baths, summer and winter apartments and porticos. Sidonius, the son-in-law of Avitus, has, in imitation of Pliny, given a prolix but obscure description of it. — *The Architect.*

Why the Pyramids were built. — The interest of the Delhi and Benares observatories lies for us in the fact that they recall a time far in the past when astronomers sought for exactness by the erection of huge structures of stone. Of these the Great Pyramid is by far the greatest and most perfect example. Britain has its own monument — Stonehenge — which has been claimed as, if not indeed an astronomical observatory, at least an astronomical temple, and many attempts have been made to determine the date at which it was erected. The difficulty, not to say the impossibility, of solving this problem in the present state of the monument may be inferred from the fact that the dates which different careful observers have deduced for its erection extend over a period of more than two thousand years. The real work of astronomy was never done in edifices like these. Nor, indeed, does it require much knowledge of human nature, essentially the same five thousand years ago as to-day, to see that the true secret of the Pyramid, the amply sufficient cause for its building, was the vanity of the ruling Pharaoh. Alike at Delhi, at Ghizeh, and on Salisbury Plain, as by the Euphrates, to "make a name" was the exciting motive. Astronomers may have been employed to superintend the work, astronomy, or the cult of the celestial bodies, may have been the excuse, but the real object was advertisement. — *E. Walter Maunder, in Knowledge.*

Cooling a Roof. — Some readers of the *Metal Worker* probably will be interested in the method I adopted for satisfying a customer who desired to have the part of a building immediately under the tin roof made cooler, owing to the illness of the occupant of one of the rooms. Between the ceiling of the room and the roof was a small air-space, which is quite generally provided in the construction of buildings, but it was insufficient to prevent the heat of the roof making itself very perceptible in the chamber beneath. As the work had to be done quickly and without any damage to the roof already in place, a makeshift was resorted to. I purchased some thick, soft, open texture wrapping-paper, covering the roof with six thicknesses of this material. Above this I laid 1-inch boards about a foot or so apart, and on the top of these two more thicknesses of the soft paper. On top of this again I laid 1-inch boards close together and weighted them so as to prevent any danger of their being blown off. I then arranged for connecting a hose with the house water-supply at the highest point in the building so that the entire roof could be wet down to further counteract the heat of the sun. The effect not only reduced the temperature of the room several degrees, but also produced a benefit that satisfied my customer and had a substantial influence upon the convalescence of the patient. — *D. S. in the Metal Worker.*

To prevent the Freezing of Gas-pipes. — A simple but effective device for preventing the freezing of gas-pipes is described in the *Illustrirte Zeitung für Blechindustrie,* consisting merely in the insertion of a wider piece of pipe just where the conduit issues from the ground or wall. For a conduit of a diameter from ⅜ inch to ½ inch, a length of from 20 centimetres to 30 centimetres of a pipe 1 inch in diameter suffices. The deposition of the water-particles contained in the gas, which on leaving the works have a temperature of about 10° C., naturally takes place just where the gas is subjected to the most abrupt change of temperature — *i. e.,* on its issue from the ground. If the external temperature is sufficiently low, the deposited water immediately congeals, and clogs the conduit. As soon as the gas has acquired the temperature of the conduit, the deposition of water and congealing cease; and this is said to be the case a short distance beyond the first cooling-point. Therefore there should be no congealing beyond the inserted wider piece, and this piece is wide enough to accommodate a thick ice-crust and to still leave a free passage for the gas. — *Building News.*

An Eye-witness on the Fall of St. Mark's Tower. 47
NOTES AND CLIPPINGS. 48

PROFESSOR BONI, who has been called from Rome to advise in regard to the Venetian campanile, is endeavoring to find some drawings of the structure which may aid in its restoration. There are multitudes of photographs and engravings of the exterior available, but nothing like a geometrical section has been found, although the archives and libraries of Venice have been searched. Meanwhile, the most valuable portions of the building have been found nearly uninjured by their fall. The whole front cornice of the Sansovino Loggetta, with its bas-reliefs and columns, and three of the angels which surmounted it, have been recovered intact, and two of the bronze statues have been found, one with the head broken off, and the other with the hands slightly damaged. The bronze gates are also uninjured, so that the cost of restoring the most expensive portion of the structure will not be large. The investigation of the brick walls of the tower shows that, as might have been inferred from their collapse, they were badly built, in some cases being merely shells, filled in with rubbish. Among the ruins have been found large numbers of Roman bricks, stamped in such a way as to identify them as having been brought from Altinum, an ancient Roman city on the mainland, near Torcello. Altinum was deserted and in ruins long before the time of the prosperity of Venice, and it is probable that the remains served as a quarry for the Venetians at the time of the construction of the campanile.

PROFESSOR JOHN W. BURGESS, of the Law Department of Columbia University, has earned the gratitude of his fellow-citizens by establishing a summer class in sculpture in the town of Montpelier, Vermont, for the benefit of the carvers and stone-cutters in the neighboring granite-quarries. The class is under the care of Mr. Charles A. Lopez, of New York, who gives instruction from seven to ten every evening, and on Sunday afternoons, so that the men can attend without losing any of their working hours. The granite-cutters are said to take much interest in the undertaking, and to show already marked benefit from the instruction they receive. Hitherto, as the American stone-cutters have been, almost without exception, destitute even of the most rudimentary notion of artistic quality in their work, the French and Italians have practically monopolized the best-paid positions, and Professor Burgess has done a good deed, the influence of which may be incalculable, in setting the example of furnishing to our own citizens some of the advantages which every stone-cutter's apprentice in France or Italy enjoys.

THE newspapers announce that two distinguished artists, both natives of Pennsylvania, Mr. Edwin A. Abbey, the painter, and Mr. George G. Barnard, the sculptor, have been commissioned to execute the decorations of the new Pennsylvania State Capitol at Harrisburg. Four hundred and fifty thousand dollars have been appropriated, it is said, to pay them for their work. We are happy to congratulate, not only these eminent artists, but the people of Pennsylvania, on the prospect that so great a work may be carried out under such auspices. Architects, remembering the competition in which the profession was so grievously ill-treated, will probably wonder how a building, the total cost of which, as they were told, was absolutely limited by law to five hundred and fifty thousand dollars, should have developed so quickly into a structure which will, it is said, cost at least five millions, and is to be decorated on so lavish a scale; but this mystery, which is not without precedent in architectural history, need not prevent the new Capitol from becoming an ornament to the State and to the country.

MR. J. C. PUMPELLY, whose interest in public matters has before been shown, writes to the New York *Tribune*, urging that trades-unions should be required to be incorporated. As he well says, most of the troubles into which union men fall, and into which they bring other people, are due to the plotting or persuasion of irresponsible men, who cannot be brought to account for the ruin which they bring upon those who trust them. By incorporation, the members of the unions would gain much. While other people would be protected by the fact that the officers and property of the corporation could be held liable for corporate wrong-doing, the union members themselves would be protected in the same way against dishonesty of their own officials, and against the attacks of other unions, which now form a considerable part of the trials of workingmen; and there is no question that with corporate responsibility would come a reasonableness and conservatism in the management of unions which they sorely need. In England, which has suffered greatly, and still suffers, from the tyrannical folly of unions, something has been done toward compelling them to assume the responsibilities of corporate existence, and there can be no doubt that this application of the good old rule, that where there is power there must be responsibility, would be as wholesome in connection with associations of workingmen as it has proved to be elsewhere.

MR. PARKES, in his presidential address before the General Assembly of the British Iron Trade Association, made some interesting comments on the decline of the iron trade in England. While American competition is now little felt in Great Britain, the American mills being fully occupied in supplying the home demand, German iron is rapidly finding its way, not only into England, but, apparently, into markets hitherto supplied from English mills. Within two years, from 1899 to 1901, the exportation of English wrought-iron diminished about twenty-two per cent, while the exportation of cast-iron fell off, during 1901 alone, about six hundred thousand tons. At the same time, the importations of wrought-iron and steel, mostly from Germany, increased from six hundred and forty-five thousand tons, in 1899, to eight hundred and sixty-eight thousand in 1901, or nearly thirty-five per cent. It is probable that a good deal of this decline of British industry before German competition is due to the short-sighted tyranny of the labor unions, seconded by the extraordinary fatuity of that group of economists which professes to find in English trade conditions of the present day the solution of social problems; but the importance of the situation, as Mr. Parkes justly observes, lies not so much in the loss of British trade to the Germans as in the prospect of far more disastrous loss when American competition again begins to be felt in the English market. It is only a very few years since the annual production of American iron, much to the pride of American public men, reached that of Great Britain; it is now about two and one-half times that of Great Britain, and is rapidly increasing. For the present, the enormous domestic consumption absorbs the whole American production, but there are already signs that consumption in this country is beginning to fall off, and any serious decline in the domestic demand would throw upon the market a large surplus of iron, which must be sold somewhere, in order to keep up interest and dividend payments. The American iron-mills, enabled by the tariff to sell at an

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

enormous profit to their customers at home, and protected by combination from domestic competition, could well afford to dispose of their surplus iron in foreign markets at cost, or less, for the sake of keeping their men and machinery employed. This phenomenon has been already observed, before the flood of domestic orders absorbed all the iron that the American mills could make; and it is reasonable to suppose that it will recur, on a much larger scale, when the domestic consumption again falls below production. Meanwhile, the resources of the Americans for producing and transporting iron at the lowest cost have been improved, and their competition in foreign markets, when it is again felt, is likely to be more serious than ever.

LA CONSTRUCTION MODERNE publishes an interesting note on the manner in which the forfeiture clause in building-contracts is treated by the French courts. A correspondent writes that one of his clients contracted for the construction of a certain building, to be completed in four months, the builder agreeing, by the contract, to forfeit forty dollars a day for every day's delay beyond the date specified. The building was not completed until fourteen days after the stipulated time, and the owner claimed the full amount of the forfeiture. The contractor refused to admit the claim, partly on the ground that the penalty was excessive, and partly because, as he said, the clause providing a forfeiture for delay was invalid unless a corresponding clause provided a premium for completion of the work before the time agreed. It is curious to find that this latter superstition, which, we need not say, has no foundation whatever, prevails on the other side of the ocean, as well as on this. The architect, who seems to have been a sensible and clear-headed man, told the contractor that the clause, as it stood, was valid, and that he was legally bound to pay the stipulated penalty; but, for his own satisfaction, he referred the question to M. Ravon, the legal expert of *La Construction Moderne*.

M. RAVON, in reply, fully confirms the opinion of the architect. In this country, as our readers know, the courts uniformly hold that the owner, under such a contract, can recover from the contractor only compensation for the actual damage that he has suffered from the delay, no matter what the agreed forfeiture may be; but French jurisprudence takes a different view. The Paris Court of Cassation, in 1881, held that "When a penal clause has been formally stipulated in a contract for work to be executed, obliging the contractor to pay a determinate sum as damages for each day of delay after the stipulated time of completion, this clause must be maintained, as being the free expression of the will of the parties, reserving to the Court the right of determining the number of days of delay chargeable to the contractor"; and this decision has been followed ever since. In the present case, the contract stipulated that notice of the claim for delay should be given to the contractor by registered letter; and M. Ravon observes that unless notice was actually given in this way the penalty could not be enforced, for the reason that, in all such cases, all the conditions agreed upon must be strictly complied with.

AS we have already mentioned, the project for the construction of a new front for Milan Cathedral, which formed the subject of a great international competition some years ago, has been abandoned. The death, soon after the competition, of Signor Brentano, the distinguished young architect to whom the commission was awarded, caused a delay in carrying out the scheme, and, in the meantime, the conservative party among the citizens gained strength so rapidly as to prevent it from being taken up again, and the fund bequeathed by Signor Togni, in 1884, to be used in the rebuilding, has now, apparently with the consent of all parties, been devoted to charity, and the Renaissance front will be left undisturbed. As it happens, however, an earlier bequest provided funds for adorning the front with a pair of bronze doors. The sculptor to whom was awarded the commission for this work, Signor Pogliaghi, supposing that a Gothic front was to be built, under the Togni bequest, made a Gothic design of great merit; but the execution of the design was suspended during the discussion over the alterations. Now, although it has been decided to retain the Renaissance front of the Napoleonic era, the authorities see no reason for changing the style of the doors, and they are to be carried out as designed for the Gothic front in which it was supposed they would be set.

THE city of Paris has taken advantage of its present prosperity to devote immense sums of money to public works. The underground railway, which is being rapidly extended, will cost nearly seventy million dollars before the lines already laid out are completed; more than ten millions will be immediately expended in street improvements; and it is said that, under the urgent advice of the medical officers of the city, nearly all the great hospitals will soon be rebuilt, at an estimated cost of about sixteen million dollars. The population of Paris is now twenty-eight hundred thousand, or nearly the same as that of Greater New York, and it is burdened with a large debt; so that the new undertakings indicate confidence in the future on the part of the Municipal Council, which, whatever its political eccentricities, has shown great prudence, as well as liberality, in its administration of the municipal finances.

IT is possible that the recent relaxation of the Parisian building-laws has done something to encourage the rapid development of the new style of French architecture, which forms, to the professional tourist, the most striking feature of recent Parisian construction. We have often illustrated the principal specimens of the new art, of which the Palace Hotel, in the Champs-Elysées, was one of the first, and is still the most conspicuous example. This has been followed by many other works, which, although, for the most part, less refined, and, therefore, less successful, agree in showing a determined revolt from the forms and fashions hitherto accepted which may contain the germs of a new and great art. We are very far from thinking that there is anything artistic in eccentricity; and the trouble that some of the "advanced" Parisian architects take to defy every kind of architectural tradition indicates a temperament unsuited to the highest artistic achievement; but the worst of the French eccentricity has nothing of the dull brutality which characterizes the works of the American or English contractor who has undertaken to "draw out" something "different" from the ordinary type, and the best, perhaps, contains the germ of a new artistic development. It must be confessed that the embryo appears, as yet, to be a very small one, but a man of genius, starting from the new principle of designing architectural forms purely as agreeable combinations of line and light and shade, without reference to precedent, may accomplish wonders.

A CURIOUS story comes from Egypt, to the effect that the Sphinx is "rapidly decaying," owing to the increased moisture of the Egyptian atmosphere consequent upon the more extended and regular irrigation of the country. It is well known that rain, which was formerly very rare in Egypt, now occurs quite frequently, and it seems not impossible that this may have had its effect upon the coarse red granite of which the Sphinx is made. Many years ago, two sculptured blocks of red granite from Egypt stood in a garden in Waltham, some ten miles from Boston. If these blocks are still there, it might be instructive to study the effect upon them of the New England climate. It is well known that the New York obelisk has suffered greatly from American rains and frosts, but it may be that the sulphurous vapors of a great coal-burning city have had their part in its disintegration, and the Waltham blocks, which have been in this country much longer than the Central Park obelisk, and have been exposed to a comparatively pure atmosphere, should afford valuable indications of the action of the weather on the material of which they are composed.

THE Germans have, with characteristic love of learning, improved their commanding mercantile position in Asia Minor to undertake a considerable number of archæological investigations, some of which have already been fruitful. One of the earliest of these explorations was devoted to the ruins of the great temple of Baalbek, which, after two years labor, have now been made intelligible, although another year will be required to complete the work upon them. Incidentally, some smaller ruins in the neighborhood have been studied, and, this summer, a preliminary survey has been made of the remains of Palmyra, Gerash and other cities east of the Jordan, with a view to their complete exploration later. Other parties have begun excavation at Miletus and at Babylon, as well as at a mound in Mesopotamia of which almost nothing is known. In Palestine, the English Palestine Exploration Fund has begun the investigation of what is supposed to have been the Biblical Gezer, and an Austrian and a German party are also at work in the neighborhood.

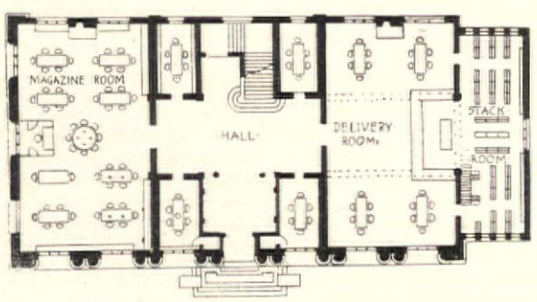
LIBRARIES IN THE UNITED STATES.[1]—IV.

TOWN LIBRARIES. — DIVISION II.

AT least two distinct types occur in the libraries selected to illustrate plans adopted in this class. The Atlanta and Davenport represent one and the Pawtucket the other. The latter has only a basement and first floor; the others have an additional floor. At Atlanta the plan is more compact, and, therefore, more easily worked as a library than the rather monumental plan at Pawtucket. The open-shelf rooms adjoining the stack-room and either side of the delivery-space are excellent features in the Atlanta Library. The Utica Library has not been erected yet. It seems to come midway between the above types. All the important rooms are placed on the first floor. Among the points worthy of note are the reference-spaces (10 feet wide) on each floor of the stack-room; the important position of the children's room, which balances the general reading-room; and the provision for special study-rooms. Libraries of this size — the cost ranging from £20,000 to £50,000 — are becoming very numerous, and there is no doubt many new developments in their planning will be always taking place.

CARNEGIE LIBRARY, ATLANTA, GA.

The Carnegie Library, Atlanta, Ga., was completed and opened last year. It consists of three floors, and is built on an isolated site. The main-building has a frontage of 116 feet and a depth of 64 feet;



First Floor: Carnegie Library, Atlanta, Ga. Messrs. Ackerman & Ross, Architects.

projecting from the side to the right is the building for the book-stack, 18 feet wide and 56 feet deep, set back 5 feet from line of frontage.

The basement is reached either from a small back entrance or from the staircase leading from the main-entrance hall on the first floor. It is 10 feet 6 inches in height. The children's room extends across the whole of the west side. It is 33′ 6″ x 58′, and well lighted on three sides. It is divided into two by a gangway 8 feet wide, leading to the attendant's desk; either side of the gangway are railings 2 feet 6 inches high, having gates in them next the attendant's desk, so each child entering or leaving is well under control. Each of these rooms has 6 tables, seating 4 readers each — tables vary in shape and height. The sizes of these tables are as follows: Tables 3 feet 6 inches diameter, 1 foot 10 inches high, chairs 1 foot 2 inches high. Tables 3′ x 5′, 2 feet 4 inches high, chairs 1 foot 4½ inches high. Tables 3 feet 6 inches in diameter, 2 feet 6 inches high, chairs 1 foot 5½ inches high.

Seats are fitted in each of the windows; they are 7 feet wide and 1 foot 4 inches high. The catalogue-files are placed either side of attendant's desk. Specimen-cases with glazed-doors, bulletin-boards with portfolios under, and shelving 8 inches deep are placed to a height of 6 feet 6 inches between the windows, as well as on the east wall. In a similar position on the east side is the work-room. It is 33′ 6″ x 58′, lighted on two sides, north and south, and a central opening from it enters directly into the stack-room, the floor of which is up 6 steps. This latter room is 17′ x 52′. The stacks are well arranged and lighted, and will take on each floor approximately 17,220 books. Two lifts with a table between, and a staircase adjoining to upper floors, are grouped together, and near at hand a toilet-room for staff is provided. There are altogether 4 floors of stacks, each 7 feet 6 inches in height. The upper floor is top-lighted, and is at present used as the cataloguers' room. The stacks themselves are especially well arranged, having ample space between for reaching the books. The two floors above are stacked in a similar manner.

On the first-floor plan the hall is placed right in the centre of the building, and is reached directly from the entrance-vestibule. It is 42′ x 20′. The main staircase opens directly out of it on the north side. To the left is the magazine-room, and to the right the delivery-room. The 4 smaller rooms that open from the hall are placed either side of the staircase and vestibule; they average about 11′ x 17′ 6″, and are used as special study-rooms and for the medical library. Each of these rooms is provided with a table 3′ x 8′ and 2 feet 6 inches high, and shelving to walls 6 feet 6 inches high. The medical-library shelving has glazed doors and a magazine-rack beneath the window. The delivery-space is 22′ x 20′ wide, the latter width being the length of delivery-counter to the public. It has in it the cases for the card-catalogue and 2 tables 6′ x 2′ for its use. On each side of this delivery-space 2 rooms are set apart for open shelves. They are divided by railings 2 feet 6 inches high, fitted with gates, and are each 25′ x 18′ 6″. Both have 2 tables, each 3′ x 8′, and 10 feet of the return of the delivery-counter on each side face towards these rooms. The counter is 3 feet wide, 2 feet 10 inches high, fitted towards attendant's desk with drawers, cupboards and shelves. There is a working-space of 12′ x 18′, with table for the attendant, and behind it is the opening to the stack-room, being the full length of the working-space. The stack-room is also approached from each of the open-shelf rooms; it is arranged practically as the floor below — 2 lavatory-basins for public use take the place of the staff toilet.

The magazine-room is the same size, 33′ 6″ x 58′, as the children's room below it, and the windows are placed on the three sides in a similar manner. The attendant's enclosure with desk is placed directly opposite the entrance. It is about 9′ x 9′, with a panelled railing 2 feet 6 inches high enclosing it, and having a gate opening into either side of the room. There are 8 tables, 3′ x 8′, 2 feet 6 inches high, each having 6 chairs, 1 foot 5½ inches high; and in the centre of the room, opposite the attendant's desk, is a circular table 6 feet in diameter seating 8 readers. Seats are provided in the window-openings, and along the front wall a standing newspaper-desk 25 feet long. Shelving 8 inches deep and roller-shelving 2 feet deep by 6 feet high occupy the remaining wall-spaces. Here will be kept the bound volumes of the magazines and the current files of all the weekly and monthly periodicals.

On the second floor the reference-room is placed over the open-shelf room and delivery-space. It is 33′ 6″ x 58′, and has the attendant's desk exactly opposite the entrance, and opening out of what will be one day the top floor of the stack. The tables, etc., and the number of readers they accommodate, are as the magazine-room already described. The shelving is 10 inches deep instead of 8 inches, and there is a case 9 feet wide with 20-inch deep roller-shelving for atlases. It is 14 feet in height and is well top-lighted, in addition to the windows front and back. A temporary panelled partition 6 feet 6 inches high separates this room from the catalogue-room at the back of the attendant's desk.

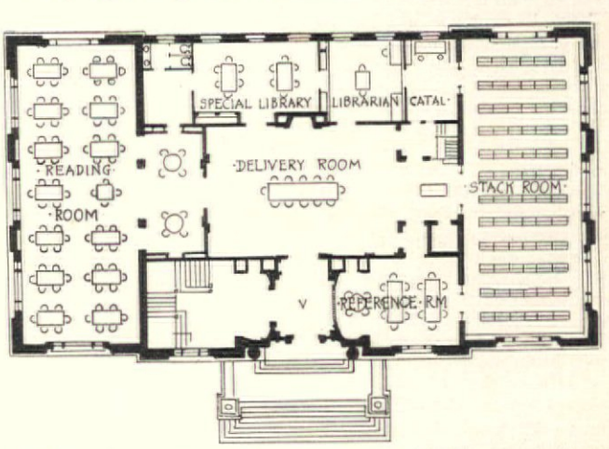
The rooms for the librarian are placed in the centre of the building, to the front a public office 21′ x 18′, and a private office 17′ 6″ x 10′ 6″. Opposite, on the other side of the upper hall, are placed the women's toilet and staff room. The latter is fitted with ten 14″ x 16″ x 6′ 6″ lockers, with 6-inch drawers at bottom and shelf at top. There is also a sink and a marble-topped table adjoining, with small gas-stoves.

The large room in another wing over the magazine-room, and of the same size, is fitted as a lecture-hall. This room will, according to the librarian's report, "eventually become the main reading-room of the library, with shelving-capacity for 5,000 volumes, specially selected."

The compactness of the plan is very marked, and it is of its type an excellent example. The total cost was £25,000, and it was designed by Messrs. Ackerman & Ross, of New York.

CARNEGIE LIBRARY, DAVENPORT, IA.

In many ways the Carnegie Library at Davenport, Ia., is similar to the library at Atlanta. It covers, though, somewhat less area, the frontage of the building being 120 feet long, with a depth of 64 feet. The site is an isolated one. In the basement — approached from entrances at both sides and by a staircase from the main vestibule above, are the 2 children's rooms, the reading-room, 25′ x 25′ with 6 tables seating 6 each (36), and the children's study, of the same size and fitted in the same way. Other rooms are provided for the reports and historic records, work-room 16′ x 18′, boiler-room 16′ x 26′, large storage-room (under delivery-room), plenum (under



First Floor. Carnegie Library, Davenport, Iowa. Mr. Calvin Kiessling, Architect.

vestibule), with inlets under steps to entrance, janitor's room, disinfecting-room, and the men's lavatory. The children's lavatory is placed off the study-room. On the first floor the delivery-hall, 26′ x 39′, is right in the centre of the building, and is reached directly from the entrance vestibule. It is top-lighted and 42 feet in height. In

[1] A paper by Sidney K. Greenslade [*A.*], Pugin student, Grissell Medallist, Godwin Bursar, read before the Royal Institute of British Architects, Monday, March 17, 1902, and printed in the *Journal* of the Society. Continued from No. 1388, page 38.

the centre is placed a large table to seat 14 readers. To the left is the general reading-room, 25′ x 60′, with small alcove at entrance between it and the delivery-room, 12′ x 30′. There are 16 tables, 13 seating 6 each and 3 seating 4 each. To the right is the delivery-counter (with work-space balancing the alcove on the other side of the hall), and the stack-room, 25′ x 60′. The latter is arranged for 2 floors of stacks, the 12 rows being each 18 feet long and the total shelving capacity 60,000 volumes. Entrance to the stack-room is accessible to the public, but controlled by electric-button snap-catch gates each side of the delivery-counter, at the command of the attendant. The reference-room, 18′ x 25′, with alcoves, is well arranged, having its entrance from the delivery-hall well controlled from the delivery-desk, and it also opens directly into the stack-room. The cataloguer's room, 11′ x 17′, and librarian's room, 17′ x 17′, with lift to librarian's private room above and work-room below, balance on the other side of the delivery-desk, and to the left of the librarian's room is the special library, 14′ x 24′. The ladies' cloak-room and toilet adjoin the general reading-room. On the second floor there are placed additional special library-rooms and private rooms for the literary circle, as well as an assembly-hall and exhibition-room. The architect is Mr. Calvin Kiessling, of Boston.

[To be continued.]

HEREFORD CATHEDRAL

IN 1877 there was a meeting of the Royal Archæological Institute at Hereford, when the late Sir Gilbert Scott, R. A., read a paper on the history of the Cathedral and acted as cicerone. He spoke as follows: —

"In giving the history of a great building, it was sometimes the case that the difficulty arose from too great an abundance of information — an *embarras de richesse* of historical facts, and such he dared say was the case when that prince among those who undertook such tasks, Professor Willis, compiled his unrivalled architectural history of Canterbury Cathedral, for in that case the most important parts of its history were so fully and accurately chronicled that Professor Willis must have found difficulty in condensing the materials, rather than in searching them out. At Hereford the case was very different, for here they found almost a nullity of historical information in regard to the building, except what was indirect and uncertain. He had to search, therefore, in every conceivable direction for such mere 'waifs and strays' of history as might suggest guesses or theories, or furnish excuses for them, which it was impossible to prove or test. In writing on Hereford Cathedral, in 1841, Professor Willis said: — 'It is much to be regretted that the period of no one part of this cathedral has been recorded with the exception of its front foundation.' How then could he (Sir Gilbert), who was no investigator of antiquarian documents, venture to give the history of a structure the builders of which, and those who were eye-witnesses of its erection, had neglected to record what they did and what they saw? But having accepted the task he begged their consideration of the difficulty he had met with, for the very paucity of information had increased the labor of seeking it, and poor as was the result, he should be ashamed to tell them the time and labor he had devoted to the task. Their sister society, the Archæological Association, had been before them on this ground, and a paper had appeared in the journal of that Association, written by Mr. Gordon Hills, which appeared to have so nearly exhausted the documentary information within reach, that he should, with the writer's permission, make free use of it, adding such information as he might have picked out elsewhere. . . .

"The see which now took the name of Hereford dated from very early times, and it was likely enough that there was a church of some importance there so early as Offa, the great King of Mercia, who treacherously murdered his son-in-law — or intended son-in-law — Ethelbert, King of East Anglia, somewhere thereabouts, in the year 793, for the purpose of adding his kingdom to his own. Hereford was then known by the name of Fernleigh, and the body of King Ethelbert was brought there for reinterment by a pious noble named Brithfrid. About 830 the church was rebuilt in stone by Milfrid, the ruler of Mercia, in honor of the now sainted Ethelbert, and about two centuries later it was rebuilt by Bishop Athelstan, in the time of Edward the Confessor. Athelstan's cathedral was, however, but short-lived, as it was burnt in 1056 by Griffin, the Welsh king, or Bruce, who slew Leofgan, the Bishop, and many of his clergy. Leofgan was succeeded by two natives of Lorraine. The first was Walter, nominated by the Confessor, and the second was Robert, appointed by the Conqueror. Robert of Lorraine, commonly called Lozinga, a corruption of Lotharingus, was consecrated in 1079, and he held the see sixteen years. He undertook the reconstruction of the cathedral, which had lain waste since the invasion by King Griffin, and he was said by William of Malmesbury to have built it of a circular form in imitation of the basilica of Aix-la-Chapelle. Now, they knew something of the church he chose for his model. It was a round or polygonal plan, imitated, as it was said, from the church of San Vitale at Ravenna, which had about the year 550 been erected by Justinian possibly in imitation of the Temple of Minerva Medica at Rome, and, more probably still, of the church of the Holy Sepulchre at Jerusalem. All those imitations were, however, but rough ones, and consisted mainly in the adoption of a round or polygonal plan. Charlemagne's church at Aix-la-Chapelle probably still existed, and was in idea very similar to those built afterwards by the Templars in rough imitation of the church of the Holy Sepulchre, which he probably had in his eye quite as much as that at Ravenna. But, however it was, the unfortunate fact remained that they had not in the Norman cathedral here at Hereford a trace or a suggestion of any of those buildings, and if Robert of Lorraine did really imitate Charles the Great's sepulchral basilica, his successors —and probably Bishop Reynelm — must have utterly obliterated his work.

"Reynelm held the see from 1107 to 1115. His reputed effigy bore what might be a model of a church, and his *obit* styled him as '*fundator Ecclesiæ Sancti Ethelberti*,' which was altered in a later hand, and he thought erroneously, to '*Hospice*.' Writers on the cathedral seemed disposed either to deprive him (Reynelm) of all claim as a builder of the cathedral, or to attribute to him the completion of the work begun by Lorraine. Neither of these suppositions seemed to him (Sir Gilbert) agreeable to common-sense. If Robert of Lorraine completed his design, or if Reynelm completed it, how was it that there was no vestige of anything agreeing with William of Malmesbury's description? Instead of that they had a church in a very straightforward Norman type — apsidal, it was true, but less pronouncedly so than usual, and bearing no resemblance whatever to that at Aix-la-Chapelle. Again, the architecture was not of the earlier Norman type, but that of a more advanced period. Nor did Reynelm complete the cathedral, for they found that this was not finished until 30 years after. He (Sir Gilbert) therefore inclined to the belief that Robert of Lorraine only began the church, and that, being a German, he was proud to do honor to the Imperial basilica of his fatherland; while Reynelm, who was probably a Norman, reverted to the manner of his own country. One could not but regret that Robert's church did not still exist, as it would have been quite unique among English cathedrals. Robert was a learned man in all the wisdom of his age. He was a poet, a mathematician, and learned in the stars and their influence on human affairs, and though intimate with Remigius, the builder of Lincoln Minster, with Walstan, who built that at Worcester, and probably with the builders of Gloucester, Tewkesbury, and other vast churches then rising, he perhaps scorned to follow in their wake, and gloried in imitating the basilica which overshadowed the great hero of his own race. Unhappily, what he had said was all they knew of the building of the Norman cathedral, excepting that it was not finished by Reynelm, but by his third successor, Robert Bethune or Betun, who held the see from 1131 to 1148, and who, having suffered, and his cathedral likewise, during the wars of King Stephen's days, lived to recover and repair the injuries incurred.

"The cathedral, then, throwing Lorraine out of the calculation, took forty years in building in its Norman form. The scheme of its design was that its nave had eight bays of not unusual Norman type, supported by massive round pillars to which double shafts were attached both to the north and south. The triforium was of moderate height and good design; the clerestory was somewhat lofty. The choir — or rather the precentory, for the choir proper was beneath the central tower — was of three bays, supported by piers, which were masses of wall rather than columns, and, judging from the great pilastering upon their inner faces, he agreed with Mr. Gordon Hills that it must have been vaulted, which was very unusual at that time in churches of so great a span. It terminated eastward in an apse, not formed, as was so frequent, by the swinging round of arcade, triforium, clerestory and aisles upon the altar as a centre, and uniting themselves together in semicircular continuity; but a separate and narrow structure, opening into the presbytery by an arch of moderate dimensions, over which the eastern wall returned in a square form. Each aisle also terminated in a smaller apse, and each of the three apses had its own separate roof. The transepts, of which one only remained, were of an ordinary type, without — at least, the remaining one was — the apsidal chapels, which are so usual. He had elsewhere shown that three not distant monastic churches of Gloucester, Tewkesbury and Pershore followed a scheme peculiar to themselves, and displayed great originality of invention. There was no trace of that scheme at Hereford. He was not sure, however, whether the nave here was not more beautiful than those of its more original neighbors. The less lofty columns, being surmounted by a well-proportioned triforium and lofty clerestory, formed a more elegant composition than the exaggerated lofty columns of Gloucester and Tewkesbury, which unduly stunted the upper stories of the nave, though it was possible that the two ranges of aisles in the choirs of those churches, running unbroken round the apse, and the continuous aisle, with its apsidal chapels, may have produced a more pleasing effect than the non-continuous arrangement at Hereford. It mattered little, however, which looked the best. They displayed two quite different systems, each being good and nobly carried out. They saw them now but in imagination, for all those churches had been so altered that the true effect was visible in none.

"He had said that the architecture of the cathedral was not early, but advanced, Norman. Its details in all the principal parts were decidedly rich in ornamental character, and very different from those of Remigius's work at Lincoln, at the consecration of which Lorraine would have been present had the stars been propitious; but no concurrence of stars could have rendered such details as those at Hereford possibly contemporaneous with those of the work of Remigius. He did not believe that a single stone of Robert of Lorraine's cathedral remained in its place. The great glory of the Norman cathedral at Hereford was its west front. It was probably the work of Robert de Bethune, and was consequently very late in

style. He mentioned that what little Norman vaulting remained was without diagonal ribs. Possibly Bethune's work was otherwise, as that feature had become frequent in his day. At some time during the Norman period the great timber hall of the Bishop's palace and the curious double chapel of St. Margaret were erected, and St. Catherine's, which adjoined. Bethune's successor was the famous Gilbert Foliot, but though he ruled fourteen years, nothing was heard of him respecting the cathedral.

"Sir Gilbert Scott then referred to the great transition in mediæval architecture during the time of the three successors of Bethune, and said that the next work done in the cathedral was the alteration of the east end by, probably, his fourth successor, William de Vere. De Vere reigned from 1186 to 1199, just the time of the two greatest Transitional works in the west of Britain, those of Glastonbury and St. David's, so that he was more likely to have been the promoter of the work referred to, as it displayed some marked resemblances to both the splendid structures just mentioned. The older abbey at Glastonbury had been burned in 1186, the very year of De Vere's accession at Hereford, and the next few years were devoted to the exquisite chapel of St. Mary, now known as that of St. Joseph of Arimathea, while the last decade of the twelfth century saw the rise of the unequalled abbey church itself. The chapel was more Romanesque in its character than the church, though both alike display a refinement of detail and workmanship, and an artistic sentiment which it was impossible to excel. They were the right glorious contemporaries of De Vere's work at Hereford. The work was a very fine Transitional character, with a large supply of that rich semi-Norman decoration which characterized the two great works alluded to; yet with other beauties derived from France, and with evidence, such as the great projection of the foliage of the capital, that it was not quite so early in its style. The great alteration Sir Gilbert Scott alluded to was the entire removal of the three apses and the substitution of an eastern aisle, supplying the deficiency in the first scheme of a continuous aisle or ambulatory round the apse, and the adding to that aisle eastward a range of chapels. The point most open to objection in De Vere's alterations was the blocking-up of the fine eastern arch of the presbytery, by which the interior was deprived of its culminating feature without the substitution of anything in its stead, and the beauty of the choir was most seriously damaged. The reopening of the arch was a work of our own age, and had done much to remedy the radical defect.

"They now arrived at the opening of the great thirteenth century, and here they had to start afresh with, if possible, still less direct information than they had hitherto found, though the church was rich in noble work of every part of the century, but every part was left to tell its own tale almost without even the suggestion of a date. He would pass over the mere guess that the first bishop in that century — Egidius de Bruce — built the central tower, the predecessor of that which now existed. It certainly was not the western tower, as some had supposed, for no such structure existed before the fourteenth century. First of all came the noble lady-chapel. This was wholly undated and unappropriated by any founder. He had come to the conclusion that the lady-chapel was somewhat early in its style, because the general details were not Transitional but developed Early English, and that a marked interval must have elapsed between the closing of De Vere's work and the beginning of the lady-chapel. It was true that at Lincoln and St. Albans they found developed Early English work at the very beginning of the thirteenth century, but where they had Transitional work of a very pronounced character up to the very end of the twelfth century they could hardly believe that the style at the same places suddenly changed without an interval. He would not, however, venture to assign it to any particular bishop. The bowing down of the vaulting upon the side-walls, which necessitated the arcading over the windows, had an Early appearance, but not so as to class it with Transitional work. He should call it a fine design of the earlier period of Early English, though the details of the crypt seemed too late even for that. The next work was the clerestory of the presbytery. It was a specimen of very advanced Early English. The windows had what Professor Willis termed 'plate tracery.' It was not improbable that the original clerestory and vaulting had become damaged by the unsettling and sinking of the tower, for he could hardly otherwise account for their having gone to the expense and inconvenience of reconstructing so important a part of the building. The style and details of the clerestory were particularly elegant.

"They now arrived at a yet more marked era in the architecture of the cathedral. The pointed style made its *début* in the Transitional work of De Vere, and they came to the second transition — that from Early English to Decorative — or from first to middle pointed. The windows in the lady-chapel were strictly lancet-shaped. Those of the north transept, to which they now came, had bar tracery — that was to say, tracery pierced in all its little spandrels and corners so as not to look like a flat surface, but like the bending about of the mullions. This invention was the Magna Charta of Gothic architecture, setting it free from all the trammels of its earlier years. The history of the see about the period when this work was introduced was remarkable, and threw more perplexity than light upon the origin of the great work. It was held from 1240 to 1268 by Peter de Aquabianca, a turbulent foreigner, who came over in the train of William, half-brother to Henry III. Aquabianca was a favorite of the King's, but hated by the clergy, and he was absent from England from 1259 to 1268 in the Holy Land. In 1264 the King, passing through Hereford, found there neither Bishop nor clergy, and the church in a ruinous state. He was enraged and reprimanded the Bishop, and threatened that if he did not quickly return and mend his manners, he would take the temporalities into his own hands. Aquabianca returned, but only to be taken prisoner and robbed of his wealth by the insurgent barons. He was imprisoned at Ordelay, and he died in 1268. If Aquabianca built the beautiful transept it was difficult to imagine how he came to have the will or the time to do so. Yet that he had a hand in it was certain. His exquisite tomb, which they might be sure nobody would have erected but himself, bears so close a resemblance to the architecture which overshadowed it as to leave no doubt that they were by the same hand. Sir Gilbert then proceeded to point out that the tower was not all built at the same time. He concluded that the work of the lower part of the transept was carried out by the Dean and Chapter in Aquabianca's time, and that it was completed by the two succeeding episcopates, somewhere about 1288. The great faults of the design were the straight-sided form of the arches and the thinness of the details of the triforium, but with those exceptions it was an exquisite architectural design. Sir Gilbert next referred to the shrine of St. Thomas de Cantilupe, and its translation from the lady-chapel to the chapel of St. John the Baptist in the aisle of the new north transept, which was partly, he dared say, built by himself, but not until then completed, remarking that they might rest satisfied that it was the *bonâ fide* shrine of St. Thomas of Hereford.

"After service in the cathedral, Sir Gilbert Scott gave an historical and architectural description of the fabric. After pointing out the various parts and their features which he had referred to in his paper, which served as an illustration of his remarks, he passed on to other parts of interest in the Cathedral. He pointed out as leading from the north porch into the nave a doorway of remarkable design, especially as to the crossing of its arch. It contains all the foliage of the Early English period, and the crisp natural foliage of the Early Decorated, which with other matters he thought showed its age to be about the same as the shrine of Cantilupe. It would follow, therefore, that the porch and the whole north aisle of the nave were built by Bishop Swinfield about 1288. The south aisle, though less ornate, he pointed out to be of the same age or thereabouts, and that consequently Swinfield must have built both the aisles and the nave. He described the style of the nave aisles as 'Early Swinfield,' and that of the presbytery aisles and the north-east transept as 'Late Swinfield.' In the north-east transept is the monument which he thought Swinfield in his later days erected to himself. These series of recessed monuments and effigies by which so many of his predecessors were commemorated in the walls of the presbytery aisles was probably owing to him. His death took place in 1315, and the question arose whether he had a hand in the rebuilding of the central tower, which Professor Willis seemed to have thought. He pointed out that two years after the accession of Adam de Orleton, in the year 1319, a remarkable circumstance took place in the history of the Cathedral. The Dean and Chapter, supported by the Bishop of Salisbury, petitioned the Pope to sanction the appropriation by the Church of the tithes of the parishes of Shrinfield and Swallowfield, in Berkshire, on the ground that they, the Dean and Chapter, wishing in past times to restore the fabric of the church of Hereford upon an ancient foundation, which the architects and builders of the time thought firm and solid, but which architects and builders in the time of the petitioners deemed to be weak and unsafe. Consequently all the money they had expended on sumptuous work to the honor of the House of God, twenty thousand marks in all, had been to no purpose; for they were now threatened with ruin so severely that there was no remedy to be had, according to the architects and builders, unless the old fabric of the church were totally removed, and on account of that and the expense caused in connection with the canonization of Thomas de Cantilupe, they were oppressed with various burdens of debt. The Pope replied in the following year — 1320 — granting them their request, and accompanied it with an assurance of his special devotion to the 'blessed Thomas,' whose canonization he had so tardily granted thirty-eight years after his decease. This led him to ask what the buildings were that were constructed on the old foundations, and what on the new? He could only conceive that they were the tower and north transept; and the question suggested itself, what had they done with the money? Sir Gilbert then entered upon a series of speculations as to when and by whom the second tower was built, citing different theories. He said it was of singularly beautiful design throughout, and drew attention to the extremely light work in the upper part, which was necessitated by the great weight of the former tower sinking and crushing all the other work beneath it. Passing on to the more interesting parts of the cathedral, he remarked that the transformation of the south-eastern chapel into a transept was probably late in the fourteenth century, when the style had much deteriorated. Not long after the beautiful chapter-house and its vestibule were erected with a great revival of artistic taste. It was believed to be 1375. The series of monuments about that time was interesting as showing the gradual passing from the Decorated to the Perpendicular style. Towards 1474 Bishop Stanbury erected his beautiful chapel adjoining the north presbytery aisle. The monuments and effigies of the various bishops were examined, and the beautiful addition made by Bishop Booth, in 1520, to the north porch was pointed out. The futile attempts at remedying the central tower were also examined. Towards the close of the

last century the western tower showed such symptoms of impending failure that several architects were consulted and the worst advice accepted, and on Easter Monday, 1768, it fell. James Wyatt was called in, and to him they owe the present western façade, which Sir Gilbert Scott described as about the dullest piece of work in any cathedral. He also pointed out the latest repairs by Mr. Cottingham since 1840. All the present arrangements of the Cathedral which had been made by Sir Gilbert Scott to suit modern requirements were also pointed out by him, and in one or two instances he expressed a doubt whether he would have made such arrangements had he to do the work over again. The cloisters, which contain numerous Norman fragments of stonework, were next examined, and the company, which had by this time dwindled down to only a few in number, lastly descended the crypt, and on reascending separated." — *The Architect.*

THE FALL OF THE TOWER OF ST. MARK.

MILAN, July 14, 1902.

ITALY has fallen under the weight of an immense disaster, which for a long time will agitate public opinion and the world of arts. The celebrated Campanile of San Marco, at Venice, the grand and elegant tower which rose near the Golden Basilica, is ruined, and this time it is no mere question of a false alarm, as formerly in the case of the impending ruin of the Ducal Palace, but it is a real one, whose effects cannot be lessened by any prudence in official language.

For some little time back, people remarked to one another that the Campanile of San Marco did not seem to have that absolute stability which every structure, ancient or modern, ought to have, if it is to keep at arm's length a disaster as sensational and irremediable as that which the Campanile of San Marco has just offered us. But no one suspected that this jewel of the artistic crown of Venice was about to fall in ruins all in a moment just as has happened. It is not long ago that it was again perceived that the structure of the campanile was defective, and its state of equilibrium compromised, a fact which was brought to attention by numberless cracks. In particular, the piers of the "contrecanne" [*sic*] were damaged, one of them being so seriously impaired that it had to be strongly banded with iron. So, each year as it passed required new safeguarding aids, that the preservation of the campanile might be guaranteed and the public reassured.

Lately, a commission of civil engineers, in conjunction with the attachés of the Bureau for the Preservation of the Monuments of Venice, having remarked once more movements in the tower far from insignificant, had settled on a plan for urgent repairs which were about to be begun. The attention of engineers was always turned upon the campanile, and this morning, July 14th, Signor Rupolo, the architect of the Bureau of Monuments, the man who was entrusted with the delicate work of the restorations in the Ducal Palace, having remarked very alarming signs, arranged that the Piazza of St. Mark should be closed to business and the public, thus giving notice of the threatening fall of the campanile, a disaster which nothing could now prevent.

In fact, this morning, at ten o'clock, the campanile fell, with all the upper portion of the tower, upon the side of the Piazzetta, producing a terrible clamor and an immense sensation.

A feeling of desolation at once spread amongst the people of Venice, so solicitous about the artistic grandeur of their unique city. The people were unwilling to believe that the celebrated tower, so long cherished by it, had no longer an existence; but alas, the campanile had doubled up on itself, and had become a mere mass of stones, a complete ruin.

At the present moment of confusion and obsession, one cannot definitely fix the responsibility, if there be any, and the Government is going to name a commission for a rigorous inquest, whose findings are to-day uncertain, although it appears that grave responsibilities do not exist so far as the attachés of the Bureau for the Conservation of Monuments are concerned. However this may be, in the shadow of this huge disaster, concerning the details of which the press will soon be overflowing, we can only take consolation in the fact that no victim of the disaster has been discovered, and this is indeed miraculous. One has only to consider the habits of the Venetians and foreigners alike, who fill the Piazza of St. Mark and the numerous shops of the Procuratie vecchie e nuove, at all hours of the day, and this consideration taken in conjunction with the morning hour, about ten o'clock, is enough to fill us with horror at the thought of what might have happened, if, as has been said, Signor Rupolo had not foreseen the possible disaster.

The Municipal Government was hastily convened, and the Mayor, after having officially denounced the disaster which had just fallen upon Venice and Italy, proposed, amidst the most sincere and justifiable applause, that the Campanile of San Marco should be rebuilt. In this connection, the municipality, for the purpose of a competition for the reconstruction, placed at the disposal of the Governmental authorities, the sum of a half million of lire ($1,000). A public subscription has been opened for the same purpose and it is certain that it will produce at the earliest moment a sum corresponding to the gravity of the disaster.

Aside from the ruin of the campanile we must, also, mourn the loss of the Loggia of San Marco, or the Loggetta of Sansovino, as it is commonly called, which was connected with the campanile on the face towards the Ducal Palace. Now it lies completely buried under the ruins of the tower — an immense heap of brick and stones, and is likely to be found, when uncovered, in a desperate condition. There is, however, a general feeling that it will be found possible to rebuild it if the fragments are sorted out with proper care, and we will hope that this may actually be done. It would be extremely happy, too, if in rebuilding the campanile a good proportion of the old material should be used, for the mere rebuildings of ancient edifices with new materials are never worthy of praise; they are mere lies, and such would be the fact with the campanile if a mere copy in new materials should be erected.

Significant damage has also fallen upon Sansovino's library, the Library of San Marco, which, at the time of its original construction, suffered from an accident which ruined one of the vaults, and caused the imprisonment of the author, who obtained his liberty through the intercession of the highest influences in the Republic.

Fortunately, the Basilica of San Marco and the Ducal Palace suffered no injury; but if the campanile had fallen forward, since it is erected *vis-à-vis* to the Porta della Carta, between the Ducal Palace and the Golden Basilica, the consequences might have been graver yet; a fact which gives us, in the midst of the gloom which has fallen on us, a certain feeling of serenity, a serenity which, in the midst of evil, allows us to perceive that things might have been worse. In short, everybody, the Venetian municipality, the Italian Government, highly moved by the disaster which I hasten to recount to you, have to-day determined to reconstruct the characteristic tower, without which the celebrated Piazza of San Marco would be unrecognizable, and this fact is something. Moreover, Italy everywhere feels the high responsibility of being, *par excellence*, an artistic country, and means to watch jealously over the preservation of its artistic patrimony, which is really the artistic patrimony of the intelligent throughout the world.

The disaster of the Campanile of San Marco has caused to be written, and will cause to be written, a quantity of misinformation upon its history, so I will give a brief *résumé* of the facts, not gathering them from newspapers and guide-books, where the truth is often as wanting as good sense in the head of a madman: —

The campanile was fully isolated, only having connected with it upon one side, that which faced the Basilica of San Marco, the loggia of Sansovino. Built of brick and Istrian stone, it was conceived with simplicity, and its *ensemble* had a *cachet* that was very characteristic. It appeared to belong to the Renaissance, just as did Sansovino's loggia and library, but in reality its origin mounted far beyond the fifteenth and sixteenth centuries; but properly speaking, the origin of the tower is obscure and uncertain.

It was founded before 948; people do not know in just what year; the works were continued up to 985 according to certain chronicles, and according to others until 1068 or 1147, while some say 1310. At all events, in 1489, the campanile was badly damaged by a fire. Giorgio Spavento was interested in the restoration which was carried out; again, in 1511, an earthquake was still more disastrous for the tower than was the conflagration of 1489. This time, the tower received the belfry-story — perhaps designed by Bartolomeo Bon, of Bergamo — a story of exquisite sobriety, which constituted the more ornamental portion of the tower. It should be noted that the author of this belfry-story has not been clearly identified, and it is only by induction that the best-informed critics of the day venture to name Bartolomeo Bon, who may be confirmed as author, or denied, if ever any documents may be found to throw light on this obscure point in the history of our monument. It must be added that the conflagration of 1489 burned the summit of the tower, which was gilded, and also attacked the Church of the Frari.

It is also to be remarked that the common belief that the tower had foundations as deep as the tower was high, and that these foundations were star-shaped, and that they even passed under the Basilica, with a platform built of tree-trunks, arranged in pyramidal fashion, from the perimeter to centre, an opinion frequently reiterated, was done justice to by the studies carried out in 1886, which demonstrated that the foundations of the Campanile of San Marco were only 5 metres deep, a fact sufficiently interesting to know, considering that the campanile itself rose to the height of 98 metres.

AN EYE-WITNESS ON THE FALL OF ST. MARK'S TOWER.

HOTEL DE MILAN, VENICE, July 20, 1902.

TO THE EDITORS OF THE AMERICAN ARCHITECT: —

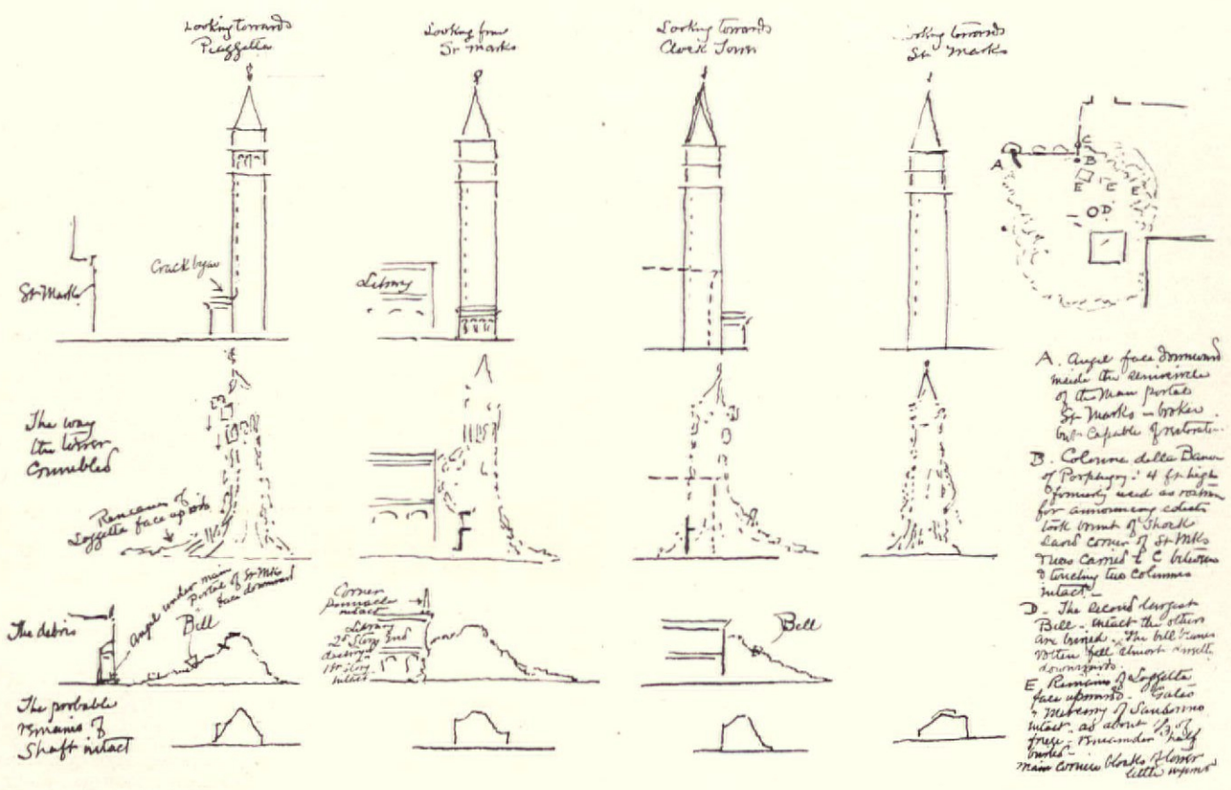
Dear Sirs, — I have telegraphed and written Mr. Peabody asking that the Institute contribute to the reërection of the Campanile. The contributions have been going on here for five days and some $290,000 have been subscribed. By the aid of Francis Wilson, Arlo Bates, who were here, and others, I got together some $800. I have written to London and Paris. The work has been put in charge of Boni, who, as we all know, is the best possible man. Meantime, there are various newspaper accounts of interviews, etc., with different architects; amongst others some American architects, who have laid the fall of the tower to the settlement of the foundation. That shows absolute ignorance of the facts.

I was here, much to my grief. From a distance I saw the angel slowly descend, swaying, but upright, and my daughter and her governess were on the Piazza not 200 feet away. They both say that spurts of lime-dust puffed from the tower about 20 feet up from the ground, and that then cracks appeared at the base in the curtain-walls between the buttresses, which opened upwards with great rapidity, and the base of the tower spread "like the roots of a tree." There was little or no shock. The angel descended in an upright position until the cloud of dust rose and covered it, and must have come down full 100 feet before toppling. When found it was directly under and within the main portal of St. Mark's.

The Italians say the tower "se sedesse" — *i. e.*, sat down upon itself. If there had been settlement it would have leaned. My own impression is this: The top of the tower has been continuously repaired with new material; the bottom less so. The Loggetta concealed the condition of the bottom wall behind it, and it was neglected. The series of windows just inside the corner in order to light the stairs was always a structural weakness in this type of tower. There has been work going on in flashing the roof of the Loggetta, which, while it seemed very slight and harmless under usual conditions, under these special conditions began to show great weakness at this point. This was acknowledged two months ago. The continuous repairs, etc., had produced in the brickwork, certainly of the outside walls, a state to which I can give no better definition than that it was a state of unstable equilibrium.

Energetic, organized action was imperative, and was not taken, from a lack of appreciation of the facts. I very much doubt if any action could have averted the disaster, after the crack, which started at the lowest window towards St. Mark's a week ago, had begun to snap from window to window, all the way up, because shoring-up would merely have transferred the weak point farther and farther up the shaft, and to the right and left on the outer wall. But the miraculous thing is that St. Mark's is absolutely untouched — not a piece of mosaic fallen. The Colume della Banda and the corner columns of the foundation were insecure. Certainly there would have been damage to St. Mark's. The Library has at its end, in the second story, two columns with arches and entablature, torn out. The Gates of the Loggetta, the figure of Mercury, and two of the carved blocks with putte are practically uninjured. The rest are buried still. I sincerely hope that America will liberally contribute. There has been a good deal of talk in Paris that reërection of the old Campanile would not express the present advanced state of architecture, and some say that the Piazza is more harmonious without it. Fortunately, to my mind, no attention is being paid to these remarks. Venice has lost the foil, the contrast to the delicacy of its art. It was a noble foil, and dominated the long lines of the palaces, from every approach. That the form of this vanished monument should be perpetuated is no mistaken conception. I have, on the other side of this sheet, rapidly sketched the past and present conditions.

Yours always, C. HOWARD WALKER.



NOTES & CLIPPINGS

ALCOHOL AS A MOTIVE POWER. — The present price of denaturized alcohol in Germany is 15 marks per hectoliter, or about 13 1-2 cents per gallon. At this price it competes economically with steam and all other forms of motive-power energy in engines of less than 20 horse-power for threshing, pumping, and all other kinds of farmwork, so that a large percentage of the spirit produced in agricultural regions remote from coal-fields is consumed in the district where the raw material is grown. — *The Gas Engine.*

CURE FOR ELECTROLYSIS. — The *Electrical Review* speaks feelingly upon the question of electrolysis, declaring that the time is beginning to arrive when reckoning of a gigantic character is to be had between electric street-railway companies and those who employ buried piping system for various purposes. After treating of the general subject, and going over the methods used by both companies, and showing how the damage is done, the *Review* says that while the current which destroys the pipes may be diminished by increasing the ground-return to the power-houses to the limit of the corporation controlling the situation, it can never be reduced in that way to zero. The remedy, it is declared, is to break up the electric continuity of the piping-system by insulating-joints. A single insulating-joint would stop more current than many thousands of dollars' worth of copper laid in multiple with it, and 20 or 30 properly distributed insulating-joints would reduce the current in a pipe line more than an almost infinite amount of copper would do. This method of preventing electrolysis is well known, and its efficacy is undoubted, but the reason why it has not been adopted is the difficulty in reaching an amiable arrangement between the electric-companies and those maintaining water-pipes. Both sides agree that the insulating-joints should be put in, but each declares that the other should bear the expense. The damage to the pipes undoubtedly comes from the trolley-companies. The companies claim that after they have spent a reasonable amount of money to protect and reënforce their ground-returns, they cannot be legally asked to do more. As there is no legislation upon this subject it looks as if the pipe-line companies would be obliged to do the work, and the sooner they go about it the better for all concerned. At the same time it seems as if in equity the companies should come together, and agree upon some means of protecting the pipes. Certainly the gas-companies should do something to protect their pipes, which do much more damage when leaking than do the water-pipes.

AMERICAN STONE PRODUCTION. — The growing tendency to more permanent structures throughout the country is indicated in the compilation of "*Mineral Resources*" just issued by the Geological Survey, showing that the value of the entire production of stone in the United States in 1901 was $60,982,060, a gain of $12,295,405 over the value of the product of 1900. This great increase in value was shared by all kinds of stone. Limestone, including blast-furnace flux, showed the greatest increase, from $20,354,019 in 1900 to $26,406,897 in 1901, or 30 per cent. Granite showed the next greatest increase, from over $12,000,000 in 1900 to over $15,000,000 in 1901, or over 26 per cent. Sandstone increased from over $7,000,000 in 1900 to not far from $9,000,000 in 1901, about 24 per cent. Marble-production increased to $4,965,699 in 1901, or 16 per cent, and slate-production increased to $4,787,525 in 1901, about 13 per cent. In the order of production, Pennsylvania, producing every kind of stone, ranks first, with a total value of $10,772,288; Vermont is second in rank, with a product valued at $5,366,740; Ohio third, with a value of $5,783,225; New York fourth, followed by Maine, Indiana, Massachusetts and Illinois in the order named, each producing over $2,000,000 worth. The increase in building-stone produced is notable. In 1900 it was valued at $10,672,598; in 1901, at $15,112,600. Crushed stone for road-making and various other purposes increased in value from about $6,500,000 in 1900 to $8,500,000 in 1901. The value of the stone imported into this country for the fiscal year ended June 30, 1901, was $1,276,602, as compared with $1,028,550 for 1900, a considerable increase, of which marble and manufactured marble constituted by far the greatest part, amounting to about $1,024,687. The total value of the stone exported from the United States in 1901 was only $1,672,876, a decrease of about $90,000, as compared with 1900. The chief export was roofing-slate, valued at $950,543 in 1900 and at $898,262 in 1901. — *N. Y. Tribune.*

DANGER FROM ELECTRIC-LIGHTS. — There is a common belief that electric incandescent-lights give out very little heat and that therefore fire-danger from them is practically non-existent. Hence it is that such lamps are frequently found disposed with much unconscious carelessness in the neighborhood of combustible materials, in shop-windows, for example, for decorative effect, and the wonder is that fire-losses from such use of the lamps are not more widespread. Many experiments have been made and recorded to show how real these lamp-fire risks are, and reference to some of them will bear repetition as possibly useful in emphasizing the need of greater caution in securing illuminating effects. In one case where a lighted lamp rested against a vertically-placed white pine-board, a spot about an inch in diameter and of a light-brown color appeared after about 4 hours. In the case of a similarly disposed strip of well seasoned varnished oak, the varnish became blistered in 3 minutes and blackened in about 15 minutes. The wood had the appearance of being charred at and near the point of contact with the lamp, but was not ignited. With a lamp encased in two thicknesses of muslin, the latter became scorched in 1 minute, in 3 minutes gave off smoke, and at the end of 6 minutes, when the muslin cover was removed from the lamp and fresh air reached its interior, it burst into flames. Where a lamp was laid on inflammable material, the effect seemed to be more rapid, due, probably, to the pressure exerted by the weight of the lamp. A newspaper was in this way carbonized in 3 minutes and ignited in 45 minutes. The lamps used were of 16 candlepower. In the instance, cited recently, it was found that on immersing a 16-candle-power lamp in half a pint of water, the latter boiled within an hour. Again, with a lamp buried in cotton-wool, the wool soon began to scorch and ultimately burst into flames. A lamp in contact with celluloid fired in less than 5 minutes. All these trials indicate in a fairly conclusive way what may be expected under certain conditions from a popularly supposed absolutely safe form of light. Intimately associated with the electric incandescent-lamp is the flexible-cord connection, and in this we have a probably even more pronounced form of fire-risk. In two cases recorded some time ago short circuits developed in cords supporting lamps not turned on, and, while the current was almost instantly cut off by the blowing of fuses, the momentary arcs were sufficient to set fire to the cords, which were oily and dirty with lint, being in a cotton-mill. In both cases strands of the fine wire had probably broken and pushed their sharp ends through the insulation, causing the trouble, and both occurrences showed that however quickly current may be cut off by properly acting fuses, the heat of the arc produced is sufficient to make the cords burn. — *Cassier's Magazine.*

SMOKE-EXPLOSIONS IN BURNING BUILDINGS. — How smoke explodes in a burning building was recently shown the Fire Insurance Society of Philadelphia in its rooms in that city by Underwriters' Inspector William McDevitt. Mr. McDevitt set a two-story building, about 3 feet high, on a table. Then he partly filled it with smoke from pieces of burned wood. Thrusting in a gas-jet, a smart explosion followed, and a tongue of flame and smoke 10 feet long shot out of the windows. The inspector also endeavored to make, on a small scale, what firemen call a back-draught, which is really a downward explosion of smoke through elevator-shafts or stairways where there are iron window-shutters; but the roof of his little house was blown off, and the smoke went up instead of downwards. The inspector used only plain wood to produce the smoke for his explosions. Varnished or oiled wood, he said, would have been more effective, as producing more and thicker smoke. Before giving his practical illustrations of the explosive force of hot smoke, he briefly explained the causes of such explosions. In a fire (he said) free carbon rises and mixes with hydrogen; methyl-alcohol, creosote, and other gases are also present in smoke. These gases become heated to the point of ignition, and an explosion is the result. Of itself, smoke would explode at a temperature of from 600 to 800 degrees, but frequently the smoke is ignited by sparks or by coming into contact with a flame. "When the smoke becomes ignited," the lecturer went on, "the interior of the building is instantly converted into a mass of flame. The Hunt-Wilkinson fire strikingly exemplified that. When I first saw the fire great volumes of dense black smoke poured out of the windows. Suddenly there was an explosion, and the smoke was transformed into such a mass of flame as I never saw before." Very thick smoke, when ignited (the speaker said) becomes a pillar of flame, and rolls through a room with such a force as to shake the walls and make the windows rattle. If sprinkled with water, there would be no explosion. Where formerly firemen tried to keep smoke in, under the impression that it smothered the fire, they now immediately break in windows or skylights to let it out. Several ways of preventing such explosions were cited by Mr. McDevitt. In large stores (he said), if an air-shaft of sufficient size were in the centre, there would be no lateral spread of fire. — *Fire and Water.*

DA VINCI'S WORK AT THE SFORZA CASTLE, MILAN. — The Roman correspondent of the London *Morning Post* draws some interesting facts from a volume just published by Signor Luca Beltrami, the eminent Lombard architect, who has done such good work in the restoration of the Sforza Castle at Milan. This volume, entitled "*Leonardo e la Sala delle Asse*," contains an account of the discovery of the Leonardo decorations in the Sala delle Asse, one of the chief rooms in the apartment of Ludovico il Moro, in the Castle of Milan, and explains the method adopted in their restoration. Nearly eighteen years ago Signor Beltrami published a letter written by Gualtiero to Ludovico il Moro in 1498, in which there occurs the following passage: "On Monday the great room of the Asse — that is to say, of the tower — will be dismantled. Magister Leonardo promises to finish it for the end of September." There was nothing to show which room of the castle might be the Sala delle Asse, nor to identify it among the many rooms in the various towers of the castle. Nor could it be proved that the Magister Leonardo was Leonardo da Vinci and not another. For several years it was impossible to make investigations in the castle, because the hall which Luca Beltrami believed to be the hall of the Asse was used as an infirmary for the horses of an artillery regiment. In 1893, however, the hall was evacuated, and a German specialist who was visiting Milan at that time discovered on the vaulted roof of the hall which Signor Beltrami believed to be the Sala delle Asse traces of painting, and a large painted shield, bearing an inscription in gold letters in which mention was made of the alliance contracted in 1496 between Ludovico il Moro and the Emperor Maximilian against Charles VIII — two years earlier than the above-mentioned letter of Gualtiero to Ludovico. Closer examination revealed the general design of the decoration of the hall, the roof of which had been painted to resemble a bower with branches entwined round several shields bearing other inscriptions. The subject and the character of the design left no doubt as to the authorship of the work, which was clearly that of Leonardo. For some years, however, it was not possible to undertake a fitting restoration of the painting, but last year a public-spirited Milanese advocate, Signor Pietro Volpi, provided funds sufficient to enable a young painter of distinguished ability, Signor Ernesto Rusca, to undertake the difficult task. After carefully cleaning all the plaster and noting accurately every trace of Leonardo's composition it was possible to reconstruct and to restore the whole design. — *N. Y. Tribune.*

NOTES AND CLIPPINGS. 55

A SERIES of tests of wood treated with various fireproofing processes was carried out a few days ago at the Massachusetts Institute of Technology, under the direction of the new Insurance Engineering Experiment Station. An official statement of the results will probably be issued later, but the New York *Times* gives a remarkably intelligent account of them as observed by its reporter. In general, a temperature of thirty-five hundred degrees Fahrenheit seems to have reduced both treated and untreated wood to charcoal rapidly and easily, both of them blazing while exposed to the heat, although the treated wood ceased to blaze in a few seconds after being removed from the furnace, while untreated wood continued to flame for several minutes. In another experiment, intended to test the comparative resistance of the two kinds of wood to this temperature, it was found that it took about a minute longer to reduce the treated wood to charcoal than the untreated wood. At lower temperatures the fireproofing treatment appeared to be more effective. At eighteen hundred degrees Fahrenheit both the treated and untreated woods blazed, and were reduced to charcoal; but, when simply dropped on a red-hot iron plate, the pieces of treated wood merely charred at the point of contact, while untreated wood blazed up, and was consumed. In the final experiment, a block house was built of pieces of each kind of wood, and subjected to fire for five minutes. The treated wood burned where most exposed to the fire, but not readily, resisting for ten minutes before it fell; while the untreated blocks blazed up, and the structure fell in five minutes. In this test, different samples of fireproofed wood were used together, and it was observed that some samples resisted the fire longer than others; but the *Times* reporter says that some sticks simply painted with fireproof paint "withstood the flame fully as well as the woods treated to a fireproofing solution which soaked through the entire stick." In regard to the question whether the fireproofing imparts any objectionable quality to wood, Professor Norton, the Director of the Experiment Station, said that he had found the treated wood much more injurious to tools than untreated wood, both because it was harder, and on account of some chemical action of the fireproofing solution on the steel, which caused the tools to rust very quickly.

MR. GEORGE EDWARD HARDING, of New York, an architect whose extensive experience gives weight to his opinion, opposes the proposed amendment to the New York Building Law, which requires woodwork in buildings more than one hundred and fifty feet high to be covered with metal, instead of being fireproofed by chemical or other treatment applied to the wood itself. Mr. Harding says that in an office-building constructed under his supervision, in which wood fireproofed by the so-called "electric" process was used, the furniture in one of the rooms took fire one Saturday night, and on Monday morning, when the office was opened, although all the furniture was found to have been destroyed, the fireproofed wood doors had confined the fire to the room in which it started. This is valuable evidence, and is confirmed by the opinion of the Chief of the New York Fire-Department, Mr. Croker, who thinks that the adoption of the proposed amendment would add much to the danger of fire in high buildings. Meanwhile, actual tests, like those already made at the Massachusetts Institute of Technology, can alone determine the question whether the treated or the metal-covered wood is preferable, and we venture to say that suggestions from architects on the best way of adapting the tests as closely as possible to the conditions which would be present in actual fires would be welcomed by Professor Norton and his assistants.

THE Municipal Art Society, of New York, has under consideration a scheme for improving the City Hall Park, and consolidating the municipal departments, which promises excellent results. At present, the business of the city is divided between the City Hall, which, while suitable and convenient, is very much overcrowded, the other city buildings in the Park, all of which are more or less shabby, or inconvenient, and various buildings outside, belonging to private owners, for which an aggregate rent of two hundred and ninety-five thousand dollars a year is paid, at the same time that the work of the various offices is separated in a very inconvenient manner. As two hundred and ninety-five thousand dollars a year is equivalent to the interest on more than eight millions, the scheme before the Municipal Art Society proposes, as an actual economy to the city in rent, independent of the economy in time and convenience, to consolidate the municipal business in a single building, or group of buildings, overlooking the Park, but not encroaching on it, while the present buildings on the Park, with the exception of the City Hall, would be removed, leaving the ground open. It has been shown that, apart from the City Hall, the present buildings in the Park cannot be satisfactorily remodelled without such a large expenditure that it would practically be better to pull them down and rebuild them; and, while it is not absolutely necessary to purchase land outside the Park to put them on, the advantage of clearing the space is obvious, and the buildings themselves would be, perhaps, better accommodated north of Chambers Street than south of it. By this plan, also, the plan of Mr. William Barclay Parsons, for improving the access to the Brooklyn Bridge, by providing an arched entrance under some public building on Park Row, could be carried out in the most convenient and artistic manner, as the bridge-entrance would form a principal feature in an architectural group extending around two sides of the Park, to Broadway. The cost of carrying out the scheme would not, it is thought, be much more than the eight and one-half millions, the interest of which is already paid out for rent; so that it would impose no real burden on the taxpayers. It is unnecessary to say that the architectural possibilities of such a scheme are magnificent, and every one interested in municipal art will hope that some way may be found for carrying it out.

THE inhabitants of Pittsburgh were treated the other day to a spectacle which may have lacked charm to some of them, in the fall of a building into an adjoining cellar. Excavations are in progress for the foundations of a large office-building on Sixth Street, and, according to the newspapers, some people passing by noticed that the next building, occupied by a liquor store with offices over it, was "careening" toward the new cellar. The police were notified, and the occupants of the building ordered out. Meanwhile, a crowd of three thousand people gathered, and after waiting two hours, they were rewarded for their patience by seeing the structure fall into the new cellar, amid a cloud of dust. As insurance policies do not cover loss by the fall of buildings, the owner of the collapsed property will, presumably, look to somebody for reimbursement, and the question whether the owner of the new cellar can be held liable will have much interest for the profession.

THE *Schweizerische Bauzeitung* adds some interesting details to the published accounts of the fall of the Venetian Campanile. The writer of the article, who, some fourteen years ago, ascertained that the tower leaned from the vertical, is inclined to think that the fall may have been due to a failure of the foundation. Time alone, apparently, will decide this question. In any case, the manner of its fall was most fortunate. The Church of St. Mark is less than a hundred feet away, and the Doge's Palace is only about one hundred and fifty feet, so that, if the tower had fallen directly forward, more than two-thirds of its length would have descended upon the church; if it had inclined toward the southeast, at least half its length would have fallen on the Palace, and, if it had inclined to the southward, nearly its whole length would have fallen on Sansovino's Library, which is less than twenty feet away. Instead of this, the masonry settled almost vertically downward, carrying away, according to one account, a corner of the Library, or, according to another account, a corner of the King's Palace, the former Procuratie, which is directly behind the Library. It seems, from the account in the *Schweizerische Bauzeitung*, that the Loggetta was injured, in 1511, while it was in process of construction, by the fall of stones, shaken by an earthquake from the pyramidal top of the tower, then nearly completed; and it was six months before the damage was entirely repaired.

AN epidemic of falling down seems to have attacked the old buildings in Europe; or, possibly, the fall of one very conspicuous one has attracted attention to the condition of the others. The Church of St. John and St. Paul, in Venice, has been declared to be in a dangerous condition, and portions of it may have to be taken down and rebuilt. This building is only about half as old as the Campanile, and, being much lower, is less exposed to decay, and the cause of the trouble remains to be explained. Worse than this, however, the London *Daily Mail* asserts that one of the great porticos of St. Paul's "threatens to collapse," and urges prompt measures for repairing it. Why the porticos of St. Paul's, which carry no important load, and have only stood for two hundred years, should think of "collapsing" is a mystery. We have often been told that the arches and piers which support the dome were in danger, but this might be explained in connection with the thrust of the arches under the weight of the dome, and the disintegration of a portico indicates some serious trouble, presumably with the foundations. It has been suspected that tunnelling in the neighborhood has led to settlements, and the matter will probably be taken in hand now by competent experts.

TWO great artists have died within a few days, Mesdag, at the Hague, and Vibert, in Paris. Mesdag was almost exclusively a painter of sea-pieces, and spent most of his time in his studio at Scheveningen, on the shore of the North Sea, a few miles from The Hague; but good sea-pieces are popular in Holland, and Mesdag, who was business-like enough to maintain a splendid studio in the city, where he could receive his distinguished friends, and show them his works, is said to have amassed a great fortune, which he well deserved. Vibert, who is also said to have gained a fortune by his labors, is much better known in this country than Mesdag, and his gentle satires on ecclesiastical luxury have been very popular here, not only in the original pictures, many of which are owned by Americans, but in reproductions. An element in Vibert's popularity was, undoubtedly, that his pictures were only very mildly humorous, the sarcasm in them sufficing simply to add interest to the splendid groups of cardinals and bishops, in red and purple robes and white lace, drinking out of gold goblets, or sitting in gilded chairs, which he delighted to paint; so that he avoided displeasing anybody in a class of subjects which Courbet's savage ribaldry made offensive to every one.

PERHAPS, no profession ever rose into popularity in this country so rapidly as that of forestry. There are already four regular schools of forestry here, in New York, Minnesota, North Carolina and Ohio, besides several summer schools, to which only those students are admitted who possess a good preliminary training; yet the demand for trained foresters already far exceeds the supply, and is fast increasing. It is said that, in the United States alone, more than two million acres of private woodland are under the charge of trained foresters, in addition to the tracts belonging to the State and General Governments; and twenty skilled foresters have been called for to go to the Philippine Islands. What will be the result of the movement remains to be seen, but it is hardly possible that a system which has, in a hundred years, added immensely to the wealth of Germany should not be of even greater benefit to the United States. It is curious that one-third of the students in the Yale Summer School of Forestry are women; and, although a great many women attend summer courses rather as amateurs than with any definite object, it is very possible that the profession may, in this country, be found to suit the sex which excels in accurate and scientific observation.

THE iron market in this country shows some peculiar irregularities. While the demand for structural steel seems to be as urgent as ever, the plate-mills, which, not long ago, could not supply their customers, now find business comparatively dull. The tin-plate factories are said to find their product accumulating on their hands, and are already struggling with their workmen over a twenty-five per cent reduction in wages. Meanwhile, imports of steel and iron continue, notwithstanding the enormous duties. A wire-mill in Connecticut is said to have made contracts for eleven thousand tons of steel billets, part from the Dominion Iron and Steel Company, of Cape Breton, and the rest from Germany.

THE great dam across the Nile, at Assouan, is completed, and the next season will witness the results of the control of the Nile inundations which it is designed to give. The primary purpose of the undertaking was to enlarge the area of cultivation in the Nile Valley, as well as to permit two crops a year to be taken from ground which now only affords one; and it seems probable that both these objects will be satisfactorily attained; while it is not impossible that the great addition of moisture to the soil and air of Egypt may still more increase the rainfall, already developed by the comparatively insignificant modifications in irrigation and cultivation, so as to change the climate of the region lying between the area of ordinary inundations and the desert. The whole cost of the works, as contracted for, is only about twenty-three million dollars, or less than one-thirtieth of the direct expense of the South African War, and it may safely be predicted that Great Britain will derive a thousand times as much credit and influence from its operations at Assouan as from those in the Transvaal.

MUNICIPAL AFFAIRS gives the result of the competition of the New York Municipal Art Society for a design for an electrolier, to be placed on the "islands" which the city authorities propose to establish, to divide the traffic in the more crowded thoroughfares. The first prize, of five hundred dollars, which includes compensation for making details for execution, was awarded to Mr. Victor A. Ciani; the second prize, of one hundred dollars, to Mr. Henrik Wallin; the third prize, of fifty dollars, to Messrs. Wilkinson & McGonigle, and honorable mention to a design by Miss Edith W. Burroughs. Mr. Ciani and Miss Burroughs exhibited their designs by models; the others by drawings only.

WE think we have already mentioned the competition for artistic advertising signs, to be held in Paris in October, following the example of the one carried out a year or two ago in Belgium. The competition is open only to French citizens, and may include actual signs, or designs for them, in any medium, and of any size. A jury of thirty-three members will make the award, and very liberal prizes are offered. The first prize is six hundred dollars; there are two equal second prizes, of four hundred dollars each; four prizes of two hundred dollars each, and eight prizes of one hundred dollars each. Besides these, the prize designs are understood to remain the property of those submitting them, and may be marked with the price at which they may be purchased by any one desiring to use them. Competing designs must be delivered at the Petit Palais, Champs-Elysées, Paris, between ten in the morning and five in the evening, on any day from the sixth to the eleventh of October. Signs already in use cannot be admitted, as the object of the competition is to encourage the production of new designs.

THE AMERICAN VIGNOLA.[1]—VIII.

PART I.—THE FIVE ORDERS.

THE GREEK ORDERS.

ALTHOUGH the different examples of the Greek Doric and Ionic Orders differ considerably among themselves, both in the proportions of the Columns and in the treatment of details, the proportions of the Entablature are tolerably uniform and are, in general, the same for both Orders, the Architrave and Frieze being both about three-quarters of a Diameter in height and the Cornice about half a Diameter (119). The Entablatures, as has been said, are about two Diameters high, however tall or short the Columns may be. Their chief characteristic is the height of the Architrave and the shallowness of the Cornice. The Diminution and the Entasis of the Columns begin at the bottom of the Shaft.

THE GREEK DORIC.

The Greek Doric has no Base, the Shaft standing upon three large steps, the upper one of which is called the *Stylobate* (113). It has generally twenty Channels (114), which are generally elliptical in section, but some small Columns have only sixteen, or even, as at Argos, fourteen (115). In a number of examples an Arris comes on the axis of the Column instead of a Channel, as is seen both at Argos and at Assos (116). Instead of an Astragal, a groove, or *Sinkage*, separates the Shaft from the Necking of the Capital, and the Channels are carried past it quite up to the Fillets at the base of the Echinus (44, 116). These Fillets vary in number. They are not vertical on the face, but follow and continue the slope of the Echinus, and their upper surfaces also are bevelled (117). The Echinus itself has an elliptical or hyperbolic profile, the earlier examples being the most convex and the later ones hardly differing from a straight line. The Abacus has no mouldings.

The Architrave also is plain, and is crowned by a Tænia, below which is a broad Regula and six short Guttæ. In the earlier examples the face of the Architrave is set just over and in line with the upper Diameter of the Shaft, but in the later ones it overhangs, coming over the lower Diameter, and the Echinus is made steeper, as well as straighter, as has been said, as if to support it.

Fig. 115.

Temple at Assos.

Fig. 116. Fig. 117.

Pæstum. Propylæa.

Fig. 118.

The Triglyphs in the Frieze are shorter and broader than in the Roman Doric, and are set flush with the Architrave below, the Metopes being set back. They are also thicker than the Roman Triglyphs, and the Channels are deeper, those at the edges cutting back at an angle of 45 degrees, the others generally at 60 degrees, and they run nearly up to the broad Fillet, or Band, that constitutes the Cap of the Triglyph. This is only as wide as the Triglyph itself, not breaking round the corners, and it is not continued between the Triglyphs, the Cap of the Metopes being narrower.

As in Vignola's Denticulated Doric, the Mutules on the Soffit of the Corona slope up, and have only eighteen Guttæ, and they occur over the Metopes as well as over the Triglyphs. The Mutules are thicker than those in the Denticulated Doric, though not so thick as in the Mutulary. The Cymatium generally consists of an elliptical Ovolo and a Fillet, the Soffit of which is bevelled. But different examples vary in almost every one of these particulars.

At the corner of a building the Triglyphs are set, not over the axis of the Column, but at the extreme end of the Frieze, two coming together and making a solid block (44, p. 53). As the Metopes do not vary in size, being nearly square, this brings the three corner columns nearer together than the others.

In the best Greek examples, the columns all slope in a little, so that the corner column, which is a little bigger than the others, has its inner face nearly vertical. The horizontal lines curve slightly, being convex up, the vertical faces incline a little, either out or in, and the mouldings are, as has been said, generally elliptical or hyperbolic in section, rather than arcs of circles.

The Columns vary in height from about five to eight Diameters, the earlier ones being the shortest, and the Entasis, or curvature in the outline of the Shaft, and the Diminution in the width of the Shaft, from bottom to top, which sometimes amounts to one-third of the Diameter, are much more pronounced in the earlier examples than in the later ones (118). This seems to show that the original of the Doric column was not a wooden post, as

[1] Continued from No. 1375, page 37.

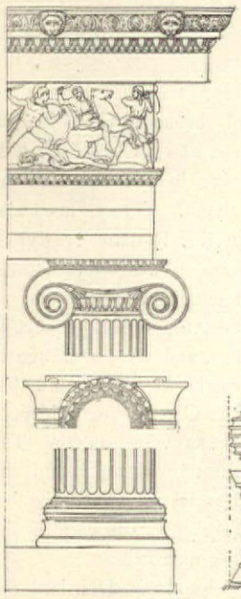

Fig. 119.

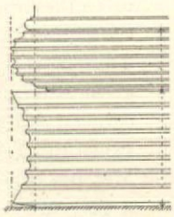

Fig. 120.

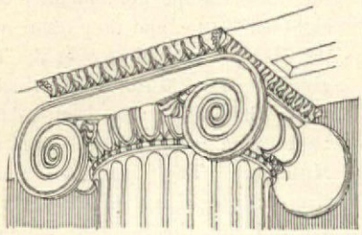

Fig. 121.

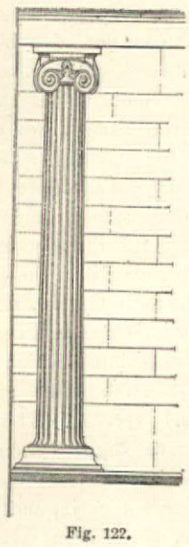

Fig. 122.

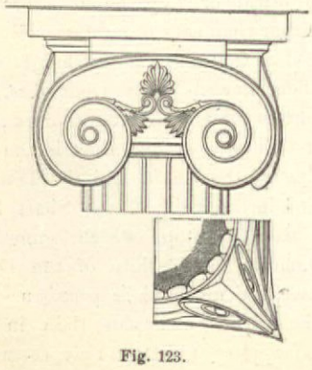

Fig. 123.

has been thought, nor a pile of masonry, but a piece of rubble-work, probably, like the rubble walls, covered with stucco.

THE GREEK IONIC.

The general proportions of the Greek Ionic Entablature are, as has been said, about the same as in the Doric, but the Columns are more slender, varying from about seven Diameters in height to more than ten, and the Architrave, Frieze and Cornice are often made very nearly equal in height (119).

The Base is like the Attic Base, except that the Scotia is larger, constituting the principal feature, that the upper Torus is larger than the lower one, that the Fillet above the Scotia projects as far as the face of this Torus, and that there is no Plinth. As the Base is still half a Diameter high, the upper Torus and Scotia are very much larger than in the Roman Attic Base. The lower Torus is sometimes very small indeed, and is occasionally omitted altogether, as at Samos (120) and in one of the Choragic columns on the south side of the Acropolis at Athens (66).

The Shaft is fluted just as in the Roman Ionic, having twenty-four channels, and the Capital resembles in general Vignola's Capital with Balusters. But the Scrolls are much larger, measuring a full Diameter and a half from side to side, and two-thirds of a Diameter from the Architrave to the bottom of the curve. The Capital, measured from the Architrave down to the Astragal, is half a diameter high, instead of a third, the Abacus is very small, consisting generally of a single Ovolo, and the *Cushion* between the Abacus and the Echinus very wide, its lower outline being curved downward (121). The sprigs of honeysuckle, accordingly, do not cover the eggs and darts, five of which are visible between the Scrolls, instead of three.

The Architrave is sometimes plain, sometimes divided into two or three bands. The Frieze, or Zoöphorus, is wide, and the Bed-mould which crowns it is often countersunk into the Soffit of the Corona, so that it does not show in elevation (119). It is noticeable that though Dentils are, historically, a distinctively Ionic feature, they are omitted in many Greek examples. The Cymatium is a large Cyma Recta, and has a Fillet and Bead below it, which is sometimes undercut so as to make a little Beak Moulding.

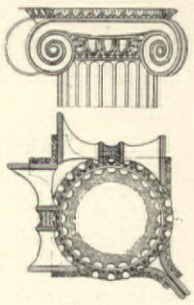

Fig. 124.

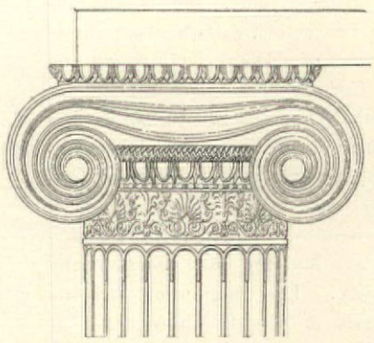

Fig. 125.

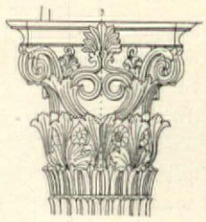

Fig. 126.

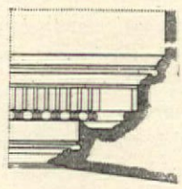

Fig. 127.

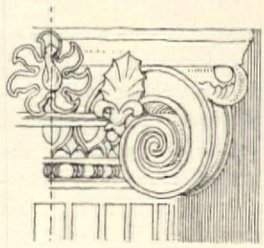

Fig. 128.

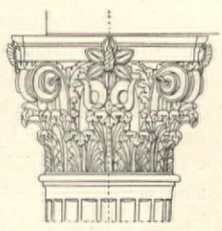

Fig. 129.

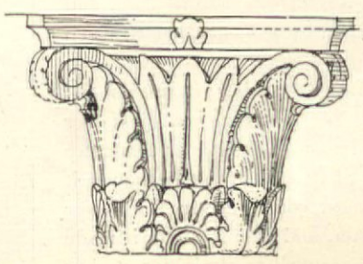

Fig. 130.

But here, as in the Greek Doric, there is a great variety in the details of different buildings.

The four faces of the Capital are sometimes made alike, with double Scrolls on each corner, as in the Roman Ionic, and these Scrolls are sometimes connected under the Abacus by a continuous curve, convex up, instead of by a horizontal line (122, 123). Sometimes a corner column shows Scrolls on the two outer faces and Balusters on the two inner ones, the double scroll on the corner projecting at 45 degrees (124). Some examples have a wide Necking, adorned with the honeysuckle ornament, below the Echinus (125, 135).

A few Corinthian Capitals are to be found in Greece, but the buildings in which they occur are in other respects Ionic, or even Doric (126).

In the later Greek Colonies in Southern Italy are found interesting varieties of all the Orders.

Their most marked peculiarity is the treatment of the dentils (127). The Triglyphs and Dentils are long and slender, and the mouldings refined in outline and sometimes separated by deep grooves, rectangular or circular, which are not to be mistaken for mouldings. The Architraves lose their importance, the Ionic Scrolls are much diminished in size, and the egg-and-dart moulding is changed into what are sometimes called Filberts (128). The Corinthian Capitals receive a local development quite unlike that which was finally adopted in Rome itself, as may be witnessed at Tivoli (129), Pompeii and Herculaneum (130). Since the revival of Grecian architecture other variations have appeared in France, Germany and Italy (131, 132).

PILASTERS.

The Romans made their Pilaster Capitals resemble those of the Columns. This works well, except with the Ionic Capitals, in which the projecting Echinus presents an almost insuperable difficulty (133).

As Pilasters do not generally diminish in width at the top, their Capitals are one-fifth broader than those of the Columns. But Pilasters are often made half a sixth narrower than the Columns at the bottom, and half a sixth wider at the top, having thus a uniform Diameter of five-sixths and a half. In the Corinthian Pilaster Capital, the extra space is taken up by making the leaves a little broader, and setting them farther apart (134).

The Greeks gave their Pilasters Bases like those of the Columns, but Capitals of their own, composed of a series of mouldings (135).

W. R. Ware.

[To be continued.]

RICHELIEU.

THE authors of the various papers on city-planning, both here and abroad, *vide* the recent *Transactions of the R. I. B. A.* and the "Beautification of Washington," have all failed to mention one of the earliest and most interesting examples of a city built on a prearranged plan by a single architect.

Washington and Annapolis, in this country, and Wren's plan for rebuilding the burnt districts of London have all been given consideration; but the little town in the middle of France, built by and named after the famous Cardinal, has not even been mentioned.

Richelieu lies in the midst of a barren plain some distance from the modern railroad-station. The present approach to the city is dull, uninteresting, prosaic; but when once we stand at closer range, under the shade of the old alleys of trees surrounding the city walls, the imagination runs riot. Nothing is changed, — the old moat is still half-filled with water and the quaint towers for the Mousquetaire defenders still retain their loopholes, while the city gates, though now without their drawbridges, are charming architectural compositions.

One can fancy the interest with which the grim old Cardinal planned this toy city. The impression is of a scene in a theatre, and one would not be in the least surprised to see His Eminence drive out or D'Artagnan and his companions loitering in the archway. Every view affords a setting for the characters of Dumas.

Standing at the principal entrance, we can see, down a clear vista through the heart of the city, the corresponding gate on the opposite side. It seems but a stone's-throw away, and indeed, is but a thousand paces.

There is no thought of radial avenues, the whole city being laid

out on a simple rectangular plan. The extreme length measures about 960 paces, and the width 360, approximately. The principal street is on the main axis, with two minor streets parallel to it. These, together with three shorter transverse streets, two of which traverse the two public squares, form the arteries of the city.

The houses are all alike, except that the buildings on the street-corners are a story higher than the others. The streets are not long enough to make this arrangement look too monotonous, but are, at the same time, sufficiently long to make the public squares the centres of interest. These squares are planted with trees in the most approved Republican manner, as seen everywhere in France.

The houses, except the corner ones mentioned above, are two stories high, in the familiar Henri IV style, with stucco walls and stone quoins and high slate-roofs broken by dormers. The cornice-line is brought down lower on the buildings around the public squares, making half-dormers of the upper stories. This makes the cornice-line of the squares lower than that of the principal street.

The church and market are the most conspicuous buildings, the church being of a seventeenth-century Jesuit type, and the market, a picturesque but unpretentious structure.

The ground on which the city is built is perfectly level, with a sufficient fall to the streets to drain everything to the centre of the town.

Richelieu was founded in 1631, some ten years after the commencement of the neighboring château in the park of His Eminence the Cardinal Duc of Richelieu.

a collection, to which Lopez, the Moorish Jew, and the most celebrated merchant of antiquities of his time, contributed no small part.

In 1642, the château was finished. In 1631, the Cardinal obtained letters-patent, authorizing him to found, adjoining his château, a city to bear his own name. He agreed to institute four fairs a year and, in order to facilitate access to them, dug a canal from the Vienne.

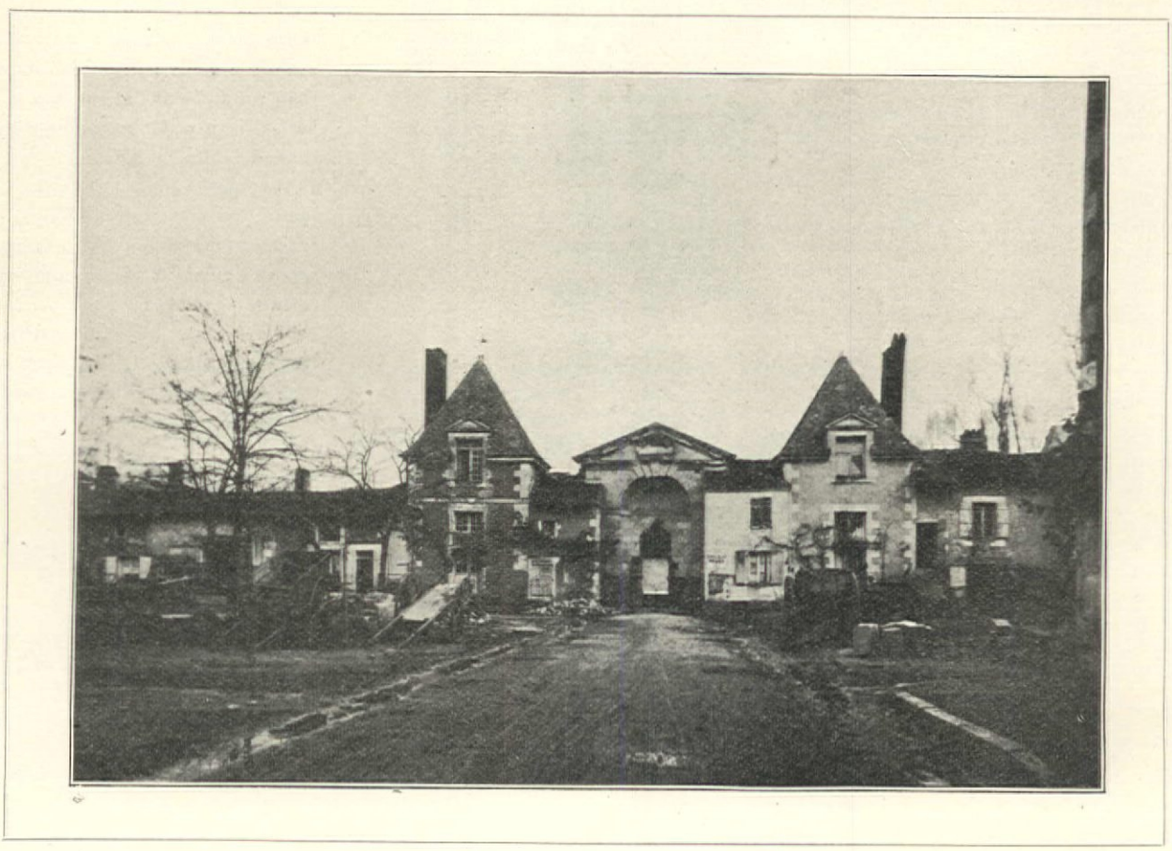
In 1639, probably at the Cardinal's request, the Pope suppressed a neighboring *cure* and installed it here. It was served by the priests of the Mission of St. Vincent de Paul. Lemercier built them a church and a charitable hospital.

For the civil administration of the new city, the Cardinal appointed various magistrates and officers, who were each obliged to build his own house at his own expense and, as it seems, according to Lemercier's designs.

The city was walled, a market and auditorium constructed and, in 1633, the twenty-eight houses of the main street, fourteen on each side, were nearly completed. The Cardinal's superintendent, de Sourdis, wrote to him: "The houses of the principal street are marvellously advanced and they are the prettiest things in the world to see. It lacks only five houses to finish it."

Finally, to complete this ideal city of the Renaissance, the Cardinal decided to build an academy and obtained a charter for the establishment of a Royal College.

He had hoped to have the King visit it, but it is said that he himself was so occupied by politics that he died without having seen the completed city on which he had expended so much money and so



One of the Small Gateways: Richelieu, Indre-et-Loire, France.

It is said that the Cardinal began this princely dwelling because he was envious to surpass the Châteaux of Champigny-sur-Veude and Bonnivet in this same Province of Poitou. Whether His Eminence was guilty of jealousy or not, the fact remains that, through his political influence, the Château of Champigny, the heritance of the famous Mademoiselle de Montpensier, was demolished. He attempted to tear down the chapel as well, but was defeated in this purpose through the intervention of the Pope. The histories give this affair as preliminary to the erection of his own château and then proceed to mention the employment of 2,000 workmen upon his palace and gardens. The men were under the direction of another Cardinal, François d'Escoubleau de Sourdis.

Richelieu's architect was also the King's, Jacques Lemercier. The problem given to him was to preserve in the magnificent buildings, of which the Cardinal had conceived the plans, the room in which His Eminence had been born, — to permit, in other words, the ministerial pride to view at pleasure the contrast between the splendor of his old age and the humbleness of his beginnings.

That this plan was detrimental to the arrangement of the interior of the château, all of its admirers have agreed, but, still, though the building was not a model of convenience, it was a veritable treasury of art. Decorated by Poussin and by Prévost, it was filled with the antiquities which Mazzarin, then a simple abbé, purchased in Italy, much thought. Indeed, there are on record only two visits of the Cardinal to his château.

At Richelieu's death, the château passed to his family. The last Duke was an *emigré*, and in 1793 the château was confiscated. In the Year XI, however, the Duke's name having been eradicated from the proscribed list, the château was restored to him; but he feared to return to France and sold the building to speculators, who immediately began to demolish it for the stonework. Napoleon made an attempt to purchase it for military purposes, but was unsuccessful, and, to-day, there are few farmhouses in the district which have not been repaired or constructed with the stonework of the château. The collections are scattered all over Europe.

As a city, Richelieu is a failure. It remains as it stood at the time of the Cardinal's death, with buildings unfinished and even the escutcheons on the completed buildings uncarved. Not a single house has been added and only the establishment of the *cure* and the building of the church have saved the city from desertion.

The Cardinal had not considered the real factors in the growth of cities; and the attempt to establish a business community at a point which was neither on a navigable river nor a great trade-route was, of course, predestined to fail.

To-day the only sounds that greet the ear in Richelieu are the noise of one's own footsteps and the splash of the water in the fountain

of the public square. The only traces of inhabitants are, here and there, white-bonneted peasant-women knitting in a courtyard or a couple of peasants drowsing in front of a café.

Thus, the little city all but deserves the name that has been given it — it is called the "Pompeii of France." W. T. PARTRIDGE.

THE NEW STYLE OF ART.

"FOR many years it has been the aim of certain architects and designers to create a new style of art that would be characteristic of the age, or, at least, different from the familiar work of the other periods. So long as this effort was conscious and predetermined it failed, as it was bound to. Broadly viewed, man's works, like his character, are not what he would have them, but reflections of himself, his mode of living and thought. To this, in the case of architecture, is added the formative or restrictive influence of the materials at his command and the climate under which he lives.

"Coincident with these fruitless efforts toward acceptable novelty the application of iron and steel to building-construction has, in this country, changed the skyline of large cities from a uniformity of five or six storied buildings, broken only by spires and towers, to a cyclopean jaggedness in which the spires are dwarfed to insignificance; and a few years more at the present rate will restore the uniformity at the high level of twenty or twenty-five stories.

"This is to premise the axiom that true growth is natural and spontaneous; and so when least expected, when the pernicious stimulators, whose bombardment of the skies brought no rain, are wearying of their labors there comes from the Old World, as all other styles have come, a new note — the expression in a new way, of a new point-of-view. What we call it is of no consequence; succeeding generations will give it a name. Whether work of allied Arts and Crafts, l'Art Nouveau, or simply New Art, it is at its best a worthy fruit of rational methods, deriving its inspiration from nature and accepting and declaring the nature of the materials. Such was the 'Gothic' when it was born; that wonderful combination of greatness and littleness, of the architect and the stone-carver. Such has been every true style. Doubtless, those times had their conservatives who scoffed at the innovations which rolled over them into history. We have them to-day and they will not recognize a style nor a form that has not had volumes written about it, the words of whose writers are their only source of knowledge. They are the dilettanti — the critics — and their gospel is literature, but it is not art. Art is vital, it lives and works; its history and expounding are matters apart.

"We all admire the old work; we treasure and copy it, and we would not be deprived of it; but if our appreciation is broad and catholic this admiration does not preclude a healthy forward impulse.

"That impulse has arrived; it has leavened the whole body of European art and industry. The Paris Exposition of 1900 was its challenge to the world. It may be that some individual notes of that challenge were extravagant and discordant; these excesses are the reaction from the paucity of recent years, but they should not obscure the perception of the merit and elegance that characterize the better work, work which fittingly marks the dawn of the twentieth century." — *The Jewelers' Circular.*

NEWBURYPORT, MASS., July 30, 1902.

TO THE EDITORS OF THE AMERICAN ARCHITECT: —

Dear Sirs, — I have read with interest your comment on originality, and the resulting correspondence in this week's issue of the *American Architect.* Apropos of this I send you an article which I wrote for advertising purposes, and which was recently published in the *Jewelers' Circular.* Being written for advertising purposes, the style of this article is not, perhaps, just what I would make it in disinterested comment; but I would not to any degree change the sentiments expressed.

I do not know that l'Art Nouveau needs defending, and I certainly would not defend some manifestations of it; but it seems to me that its relation to the accepted styles should be defined; and I do not remember having seen such definition. As a contribution to this subject, I hope this will interest you; and it may move you to a fuller exposition of the matter.

Very sincerely yours, GEORGE P. TILTON.

[MR. TILTON, whose article, "written for advertising purposes," — and it is a pity that more advertising matter has not its character — is published above, is not the only correspondent who has taken us seriously to task on the supposition that we were having a fling at l'Art Nouveau — Heaven bless the name — whereas we were simply chiding those who make originality the prime objective of their artistic endeavor. The man who sets about his work with the single intention of being "original" will inevitably produce upon the onlooker the same effect that Dr. Holmes produced when he sat down "to write as funny as I can." A confirmation of the belief here expressed will, we believe, be found in the illustrations we reproduce this week from the pages of *Architektonische Monatshefte,* which has assumed the rôle of champion and promoter of l'Art Nouveau — after the German interpretation, be it understood. There is a good deal that is attractive in some of the manifestations of l'Art Nouveau where a designer of real ability applies its rules — if there be any such — to problems in whose solution it is proper to apply them, but we have seen woefully little evidence as yet that structural architecture affords a proper field for their application. The punching of a façade full of seventeen different kinds of openings — none properly structural — and wilfully calling them doors and windows is not the execution of an architectural design. Nor is the giving to outlines and projections the *molle* curves and surfaces which invite the rain to keep the wall continually saturated with moisture, because there is no proper "drip" to the projecting features, good construction; nor is the substitution of soft and meaningless shades for bold shadows necessarily a proof of genius in architectural design. The whip-lash line — the distinguishing line of l'Art Nouveau — with its unequal flexions and suddenly reversing turns and twists, is a ductile, not a structural, line; it has no static value, as an architectural line should have. It is admirably in place in jewelry, in some of the minor applications of wrought metalwork, and is excusable in furniture, since every one knows that there the static form, the stability, is due to fish-bones and horse-hoofs, and it doesn't make much difference how form and material are vilified. But architecture has a greater dignity than jewelry or furniture and deserves greater respect than it usually receives at the hands of originals and the inventors of new styles. We thoroughly believe in progress, but not at the expense of precedent. — EDS. AMERICAN ARCHITECT.]

NOTES AND CLIPPINGS

PERHAPS THE LARGEST TREE IN THE WORLD. — What undoubtedly is the largest known tree in the world has been discovered on the Government reservation far up in the Sierras, in California. Six feet from the ground it took a line 150 feet 8 inches long to encircle the tree, making it about 51 feet in diameter. — *Exchange.*

HICKORY PINE AS A FOREST-MAKER. — In writing upon methods of conserving the water-supply of the country, in *Forestry and Irrigation,* T. P. Lukens says there are two ways of reaching the result, namely, to build storage reservoirs, and to clothe the mountains with trees and

see that they are not destroyed again. Even to build the reservoirs would be useless, unless the water-sheds tributary to them be forested, as the reservoirs would soon become filled with silt if the mountains were bare, so the only hope would be to bring back the forests. He declares that it is easy to perpetuate a forest by planting another in its place when a tree is removed. All conditions are favorable then, but after repeated fires over the length and breadth of the mountains the conditions are not favorable for tree-growth. The tree best fitted for reforesting, he says, is the hickory pine (*Pinus attenuata*), which grows on fire-swept slopes from San Bernardino to Shasta, in California, which he describes as follows: "Not many travellers ever see it, and of those that do but few would notice it except for its strange appearance which its life-store of cones give it. The tree is usually small, early bearing, found on sunny slopes of the Cascade range to the northern Sierra, and southward (rarely on the coast ranges) to the San Bernandino Mountains. Its cones grow in circles, strongly defined, narrow and pointed. They are 3 to 8 inches long, and remain on the trees unopened for an indefinite number of years. The outer scales have conical, quadrangular tubercles, terminated by a very short, triangular, firm prickle. The leaves grow three in a sheath, 3 to 7 inches long. A peculiarity of this tree is the tapering character of its cones at the base, whereby they oppose so little resistance to the growing trunk that the annual layers, instead of crowding off the cones (as in most other species), often envelop them completely. They are sometimes found in large trunks still unopened and the seed good. The cones are borne in whorls, first around the main axis of the tree only. As the tree grows and branches freely, which it will do where not crowded, then cones are borne about the limbs. I have counted as high as 500 cones on a tree 50 years old, each cone containing 124 fertile seeds, which are small, there being 20,000 to the pound. The seed has a wing 1 inch long and one-fourth inch wide. When a fire sweeps through a grove, if severe, it kills the tree. The heat melts the resin with which the cone is sealed, and the second or third day after the fire the winged seeds take flight and plant a far greater area than existed before. Thus, after each fire the forest becomes dense, crowding together for protection until at last they defy the fire, for where they grow so closely together as to occupy all the ground, they will resist fire. This persistence of cone, coupled also with the firm coherence of their scales for an indefinite length of time, is an important fact, for it ensures better propagation, if not the very existence, of the species. It is found that the seeds in these long, closed cones are always in good condition, however old the cones. They seem to declare not only that this species of tree shall be its own survivor, but also that it may extend its dominion over territory which has been cleared of trees. So we may expect that through the improvident or wanton conduct of man, while it destroys by fire the noble sugar and yellow pines of our vast forests, this cunning little provident tree, fighting now for room to stand upon and crowding close together for greater strength, shall, after long waiting and at last fire-killed, unlock its store of life germs and scatter them with sailing wings on the wind to reforest the mountains. No tree shows more greenness or symmetry of growth than the *Pinus tuberculata* when not crowded. Its desire seems to be to cover the ground, if not in numbers, then with wide-spreading branches. Trees are to be found 150 feet high, with a body 2 to 3 feet in diameter. I have never found one of them dying from old age. They thrive where other trees would not attempt to grow — on the steep, hot, rocky slopes. Their roots penetrate every little crevice to an incredible depth, opening channels for the conservation of water and mulching the surface with their foliage."

Art-study in Italy. — His Majesty's Chargé d'Affaires at Rome has sent to the Foreign Office the law regulating entry without payment of the ordinary fee to the national museums, galleries, excavations and monuments of Italy which has been approved by the royal decree of April 13, 1902. The privilege of free entry is by the law accorded to foreigners who are (*a*) artists, (*b*) art-students and art-critics who have issued noteworthy publications, (*c*) professors of archæology, history, literature and art; (*d*) pupils of archæological, historical and art institutions; students in departments of literature and philosophy and in schools of practical engineering. Applications for a general permit for free entry to all museums, etc., must be sent to the Ministry of Public Instruction on stamped paper of 1 lira 20c., with an unmounted photograph of the applicant, not to exceed 5 centimetres by 8 in size. Applications for free entry to archæological and artistic institutes in a single town must be sent on stamped paper of 60c. to one of the heads of the institutes, and if the permit is required for more than a month a photograph must be sent of the size mentioned above. The applications must be accompanied by the following documents: For persons under (*a*) and (*c*) by an academical document *visé* by the Italian diplomatic representative or Consul in the country to which the applicant belongs, or by the diplomatic representative of that country in Italy. For persons under (*b*) by one of the publications which they have issued. For persons under (*d*) by an official document showing that they stand on the books of the institutions mentioned under that heading for the year in which they apply. The document must be *visé* as in the case of documents furnished by persons under (*a*) and (*c*). As his Majesty's diplomatic representative at Rome is not always in a position to authenticate without previous inquiry documents issued by institutions in the United Kingdom, art-students, etc., are recommended to have such documents countersigned by the Italian Consular officers in this country before leaving. — *N. Y. Times.*

Lumber Trade moving Southward. — Expert opinion is that ere long the South will become the centre of the lumber trade of the United States. Signs of the movement southward are already visible. Close observers of the situation are not surprised at the changed conditions. The pine-forests of Michigan and Wisconsin have been practically depleted, and dealers in this class of lumber have been forced to look elsewhere for supplies. Recently large tracts of Southern timber-land have been purchased by Northern operators, and they are now arranging to develop them upon an extensive scale. The Southern forests contain several varieties of lumber well known in Northern markets, besides many beautifully marked hard woods suitable for cabinet-work and inside finishing. There are vast areas of such land in the South, and the indications are that for many years this industry will be one of the most profitable in "Dixie." Since 1890 the lumber trade has made great strides in the South. The New York *Journal of Commerce and Commercial Bulletin* has compiled a table showing that during the ten years ended in 1900 the aggregate value of products of the lumber industry increased $128,885,602. Of this gain the thirteen Southern States furnished three-quarters. According to the same authority, the lumber business in Michigan and Wisconsin declined $32,000,000, or more than 38 per cent.; other Western States which are extensively engaged in the lumber trade also suffered heavy loss. In some of the Northern States the business continues to expand, but the percentage of gain is not as great there as it is in the South. Not only in lumber is the South forging ahead, but also in cotton manufacture, coal, iron and other lines. This section has supplanted the Eastern States as the largest producer of coarse cotton goods in the United States, and it is predicted by many that the day is not far distant when it will also become the leading manufacturer of the finer grades of cotton goods. — *Baltimore News.*

Copper-plated Doors. — It is reported that a process of covering wooden doors with sheet-metal by means of electrolysis is now being experimented with at Bridgeport, Conn. The excellent fire-resisting qualities of a wooden door covered with tinplate have long been recognized, since the metal covering prevents the wood taking fire, while the use of wood for the framing avoids any risk of the warping of the door by heat, allowing flames to pass through, as has happened with doors built wholly of iron A tinplate-covered door has, however, a poor appearance, and is therefore suitable only for workshops and warehouses. By depositing copper or bronze electrolytically, it is hoped to provide doors suitable for buildings of all kinds. The method followed is to place the carefully finished wooden door in a hot solution of fossil-gum in linseed-oil. This completely closes the pores of the wood with an impervious varnish, so that on transferring the door to the electrolytic bath the solutions are not absorbed. On removal from the varnishing-bath, the edges of the door are bound with sheet-copper fixed by cement, and the rest of the door is then covered with a conducting layer of bronze powder, after which the whole is placed in an electrolytical bath and copper deposited over the whole surface. — *Engineering.*

New York Sidewalk Vaults must be paid for. — Maurice W. Deshong, who some time ago sued the city to recover $914, which sum he alleged the city authorities compelled him to pay "under duress and actual compulsion," has received a set-back in the Appellate Division of the Supreme Court. In an opinion handed down by Justice Ingraham lately, in which Justices Van Brunt and Hatch concur, the action of the lower court in dismissing the case is sustained. Deshong is the owner of the premises at 54 and 56 West Third Street. Some time ago he decided to rebuild. When the building was originally put up there was a vault under the sidewalk. When rebuilding, Mr. Deshong attempted to reconstruct the vault, but the city interfered, and Mr. Deshong was ordered to get a permit from the city authorities. For the permit he had to pay $914, which he did under protest, and sued to recover the amount, claiming that inasmuch as the city had never made any charge for the original vault, they had no legal right to charge in the second instance. In his opinion, Justice Ingraham said: "It is too well settled to need citation of authorities that no person can obtain a right against the public to use a public street by prescription. There is nothing to show that the plaintiff or his predecessors in title ever acquired anything more than a mere license to maintain their vault, which was revokable by the public authorities. There is certainly no presumption that the public would be estopped from at any time resuming possession of the street or compelling the owner of the property to remove the vault." — *N. Y. Times.*

A modern Log-cabin. — On Warren's Island, off the coast of Maine, is being erected what is properly described as "a palatial log-cabin." It is composed of spruce-logs, and costs the tidy little sum of $75,000. The entire island on which this summer palace is erected was purchased by the late William H. Folwell, of Philadelphia. Mr. Folwell died before the completion of the house. The work is now superintended by his son, William H. Folwell, Jr. Some idea of the size of the "cabin" may be gained from consideration of the fact that there are 22 sleeping-rooms on the second floor. On the ground-floor there is a fireplace of brick and granite, the mantlepiece being of marble, 12 feet in length, 3 in width and 9 inches thick, the whole piece of work weighing some 40 tons. — *N. Y. Tribune.*

The Duke of Norfolk's Cathedral. — The death of the afflicted Earl of Arundel gives a pathetic added interest to the great cathedral which the Duke of Norfolk is building at Norwich. It was originally designed, in the Duke's own phrase, as "a thankoffering to God after my most happy marriage." But when the nave was completed and opened by Bishop Headley, another purpose was associated with it. "This noble church," said the Bishop, "was the offering of the piety of one whom we pray God to bless. When he planned and offered it, it was a thankoffering for happiness. But since then God has manifested His holy will in visitation and sorrow, and the founder hopes, in this offering, for God's blessing upon those who are near and dear to him." Building is now proceeding on the chancel and choir; and the finished cathedral will be associated with the memory of the Duke's dead son — *Westminster Gazette.*

NOTES AND CLIPPINGS. 64

THE General Committee of the Philadelphia McKinley Memorial has issued its programme of competition for the monument to be erected to our lamented President in Fairmount Park. The Memorial, the cost of which is limited to thirty thousand dollars, is to include a portrait-statue of President McKinley, with a suitable architectural setting. Designs must be shown by models, at a scale of one and one-half inches to the foot, which must be delivered to the Secretary of the Committee, prepaid, before March 2, next. Five equal prizes are offered, of five hundred dollars each, and the author of one of the prize designs, if, in the opinion of the jury, any one is deserving of such distinction, will be recommended for employment to execute the work. The jury is an excellent one, consisting of Messrs. Wilson Eyre, Jr., Theophilus P. Chandler, Edward H. Coates, Charles E. Dana, J. Q. A. Ward, Paul Bartlett and Frank Miles Day. Competitors may be quite sure that no favoritism, carelessness or underhand dealing of any kind need be expected from such a jury. Further particulars of the competition, which is open to all artists, may be obtained from Mr. Charles J. Cohen, Secretary of the Committee on Design, 320 South Broad Street, Philadelphia, Pa.

A CASE of interest to architects and real-estate owners came up in the Appellate Court of Indiana a few days ago. The Western Union Telegraph Company, by its agents, injured certain trees in the public highway in front of the estate of Martin T. Krueger, who sued the Telegraph Company for damages. The question came before the Court whether the plaintiff would have a right of action for the destruction of trees in a public highway, even though he owned the fee in the portion of the highway in which the trees were situated. It is extremely common in this country for the fee in public streets and highways to be vested in abutting owners. This is the case, we believe, with many of the streets in New York, and any decisions which define the rights of the owners of the fee in such highways are of great importance. In the present instance, although no evidence had been submitted as to the character of Mr. Krueger's ownership, the Court said, as a general principle, that "An abutting owner, who owns the fee in land upon which a highway is located, is the owner of the soil, and of trees growing thereon, and of mines and quarries thereunder, so far as such ownership is not inconsistent with the public use. The municipality has the right to use these only in so far as they are necessary in the construction and maintenance of the way for the public use. Such an abutting proprietor, as to shade trees growing in front of his property, and upon land the fee of which he owns, has the rights and remedies of the owner of a freehold, subject only to the public easement." It will occur to architects of experience that this doctrine may be applied to other matters besides shade trees. In regard to vaults under sidewalks, for example, it would seem that, in highways of which the abuttors own the fee, this ownership would carry with it the right to construct and maintain vaults of any kind which did not interfere with free passage through the streets. It would, of course, be objected that the municipality might wish to construct subways in the streets, and that such vaults would interfere with them; but the implied contract between the property-owners and the municipality, at the time the streets in the business parts of New York and Boston were laid out, contemplated nothing of the nature of an underground railroad through the streets, and no considerations of public convenience can insert anything in a contract which was not contemplated by the parties when the contract was made.

A LARGE building of slow-burning construction was partly burned a few days ago in Pittsburgh. The floors, which were of heavy timbers, covered with three-inch pine plank, and this with one-inch maple flooring, resisted the flames very well, but the water thrown on the fire swelled the maple flooring so much as to push out the brick walls several inches. It seems that, in some of the floors, the maple flooring was simply lifted in ridges from the planking by the effect of the water; but, in certain stories, where a heavy load of boxes of glass prevented the boards from buckling upward, the whole movement was lateral. Architects will reason from this occurrence that maple upper floors in warehouses, if of large extent, ought not to be too dry before laying. In most cases kiln-drying is avoided under such circumstances, but it is important to keep the floors tight, and these boards, if not kiln-dried, seem to have been laid with very close joints. It may be observed that many architects who use the slow-burning construction pitch their floors slightly, and provide outlets, by which water thrown upon them to extinguish fire may escape without soaking the boards; and if, as is sometimes done, a little gutter is contrived in the flooring at the two sides of the building parallel with the floor-boards, the swelling of the latter will not affect the walls.

CERTAIN architects of the highest ability and distinction have, in the performance of what they conceived to be their duty to their employers, incurred the ill-will of an unimportant local union, affiliated with the International Building Trades Council, and the President of the offended union is now engaged in travelling about the country, endeavoring to secure from all unions connected with the Council a pledge to refuse to do any work on buildings designed by these architects. Under the system of mutual support in their attacks on other people which prevails among the unions, it is difficult to see how the organizations appealed to can refuse their coöperation in the contest, although, as the architects in question have a very extended connection throughout the country, the effect of refusing to work under them will simply be to throw a great deal of employment of the best kind into the hands of non-union men. In fact, it is not impossible that the bullying attitude which the building-trades unions have, of late, seen fit to assume toward architects in many localities may prove the most effective means ever devised for the humiliation of organized labor. A firm of architects like the one in question has, on an average, probably ten thousand men constantly working from its plans, and under its directions. It would be a simple matter, especially in these days of abundant capital, and easy organization, for these architects, or any others of equal capacity, to place themselves at the head of the designing department of a great construction company, employing only its own men, operating its own mills and workshops, and carrying on its operations without troubling itself about union rules or union men. A great deal of the best building work of the Middle Ages was done by coöperative associations of this kind, consisting of men accustomed to work together, under the guidance of architects whose designs they were skilled in interpreting; and, at the present day, the great building companies and firms employ very largely their own men, without concerning themselves about local unions. The latest of these building corporations has a capital of sixty-six million dollars. On such a capital, the corporation, presumably, expects to do a business of at least two hundred million dollars a year; or, to put it in the form favored by the political economists, to keep at least two hundred thousand men continuously employed, responsible only to it, and travelling from place to place as their services may be required. Against such an organization as this the unions

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

will be powerless. The corporations, with men trained to help each other, and to use the labor-saving machinery provided by the most skilful engineers, can compete at great advantage with contractors who have only the quarrelsome, unscrupulous and treacherous unions to depend upon for labor; and the day may not be far distant when in the building trades the only chance of employment will be found in the permanent force of building corporations. If anything could hasten this transformation of the great industry of building, it would be the attempt of the unions to discipline or injure architects, who, as the leaders of the building world, not only participate, from the first, in plans for the improvement of real-estate, but control, with almost absolute discretion, the manner in which such plans shall be carried out.

THE people who are, or who soon will be, toasting their food in front of wood fires, and shivering in unwarmed houses, may take from their troubles a lesson in regard to the methods of the union tyrants in this country. As every one knows, the dispute in the anthracite coal region is not over wages, but over the question of the "recognition of the union," that is, the submission of the coal-mine owners and the public to the dictation of irresponsible union magnates, who have their private ends to pursue, know perfectly well the pecuniary and political value of their influence, and are anxious to have frequent opportunities for exerting it. The example of the prosperous subsequent career of the most prominent figure in the great railway strike of ten years ago has, naturally, not been lost upon the professional agitators, and "labor troubles," intended to annoy and distress the public for the furtherance of their personal schemes, are likely to continue until the community is aroused to a better comprehension of the subject than it now possesses.

IN the present case, the owners of the coal-mines have been paying, and are ready to pay, wages far higher than the Hungarians and Lithuanian-Russians who form the majority of the miners could ever hope to earn in their own country, and many thousands of new men stand ready to take the place of the strikers as soon as they can be guaranteed security in doing so. Unfortunately, the Hungarian and Russian peasants, in addition to being grossly ignorant and degraded, possess the quality of being disposed to follow like sheep any one who gains authority over them. It is a saying among military men that Russian soldiers will march into the sea, or over a precipice, rather than question the propriety of an order given them, and this disposition has made the miners an easy prey to the agitators, whose more intelligent constituents have, of late, been getting rather unruly. In combination with their sheeplike docility, the Hungarians and Lithuanians have also a ferocious side to their character, which makes them the most dreaded and dangerous portion of the foreign community, and it is not surprising that the new men, who would gladly take employment in the mines, do not dare to face their hostility, which, as they know, is only feebly kept in check by the small show of military force on the part of the State authorities. While we have no sympathy for monopolies, which, by combination, seek to control, not only market prices, but the price of labor, it seems to us that, in this case, where the public must choose between a tyranny of bankers and railroad presidents on one side, and one of irresponsible and unscrupulous agitators on the other, it should, for the moment, favor the former, as being not only less dangerous to the community, but more amenable, later, to the control of law; and, whatever may be our private griefs against the "coal barons," it is better to avoid encouraging their opponents to further exertions, by talk of "forcing a compromise," than to run the risk of putting in the hands of the agitators weapons which will be used against us in the future, and of reducing to despair the anxious seekers for employment who are struggling with a monopoly more reckless and cruel than anything that we have to contend with.

AS to the question of the substitutes for anthracite which must, whatever may be the outcome of the strike, be very extensively used for the next six months, there is much that might be done to improve present circumstances. It is probable that the recent ordinances prohibiting the use of soft coal in cities, which are suspected of having been promoted, if not devised, by the anthracite trust, will be relaxed, the "coal barons" being now vitally interested in diminishing, rather than increasing, the demand for their product. Of coke, which has already come into extensive use for stoves and ranges, the supply is limited, and, even in the cities, it will form a very feeble resource. The best substitute for anthracite, for household use, would probably be the compressed blocks, made of the dust, either of hard or soft coal, mixed with tar and other substances, possibly silicate of soda, and pressed in moulds, which form almost the staple fuel in France and Germany, both for railway locomotives and domestic use. The blocks used in Parisian households are of the size and shape of half a billiard-ball, and have the great advantage over soft coal of retaining their shape while burning, instead of crumbling. For such blocks, properly made, there would be now an enormous demand, and it is singular that some one should not already have placed on the market in this country a manufacture which should, under present circumstances, bring fortune rapidly to the producer. Blocks of this kind are, or have been, manufactured in a small way in Massachusetts, but no attempt has been made to place them on the market, and nothing seems to be publicly known of the results of the experiment.

AN International Fire Exhibition is to be held in London next summer, under the auspices of the British Fire Prevention Committee. The affair is to be undertaken and carried on by a corporation, known as the London Exhibitions, Limited, which owns extensive buildings and gardens at Earl's Court, within the limits of London; but the technical direction will be confided to the Fire Prevention Committee. Besides a comprehensive collection of appliances for extinguishing fires, saving life in conflagrations, and caring for injured persons, the Exhibition will contain examples of fire-resisting construction in wood, metal and other materials, including fireproof doors, shutters, screens, wire-glass and so on, besides protective coverings and impregnated materials of various kinds; and including also equipment, in the shape of protective signals, theatre curtains, sprinklers, pipe casings and similar devices. The Exhibition opens in May, and continues until October. Exhibitors are charged for floor-space, at the rate of four shillings per superficial foot, with a minimum charge of forty pounds; but there are no further expenses, beyond the cost of transporting goods and fitting up stands and show-cases. It is intended to hold "tournaments" and competitions of fire-brigades and ambulance-drivers, and the Exhibition Company provides music, illuminations and other attractions.

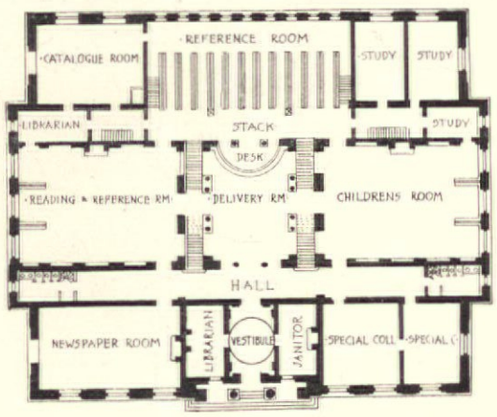
AN almost touching story of devotion to art is to be found in the account of the Dutuit bequest to the city of Paris. Many years ago, two brothers and a sister, the children of a rich contractor, were left orphans. One of the brothers wished to become an artist, and entered himself as a pupil of a distinguished painter. After several years of patient effort, he became convinced that nature had not endowed him with the talent necessary to make him eminent, and he modestly left the field to men more gifted, and devoted himself to collecting objects of art, with the avowed intention of presenting them to the community. More than this, he communicated his enthusiasm to his brother and sister, and they joined him, both with their money and their efforts, in his labor of love. Beginning with comparatively modest pecuniary resources, but with educated discrimination, and untiring zeal, the three orphans brought together, in the course of years, a collection valued at eight hundred thousand dollars, which has now come into possession of the municipality; and, with this, M. Dutuit has left a fund of six hundred thousand dollars, which will be employed in completing the Petit Palais des Beaux-Arts, in which the collection, consisting of ivories, carved furniture, porcelain, bronzes, pictures and other objects, will be deposited.

THE New York Fish, Game, and Forest Commission has under consideration a plan for propagating and raising young trees, to be given, when old enough to transplant, to towns and private citizens, to be set out on denuded lands. The professional nursery-men are, perhaps, not likely to view this scheme with favor, but, as neither towns nor private owners of barren lands are likely to have much money to spend on nursery stock, the intervention of the State, to furnish young trees for planting where none would otherwise be planted, cannot but be beneficial to the community. On a large scale, young pines and oaks, well rooted, and ready for development into vigorous trees, can be produced very cheaply, and the fact that they were available would induce many people to use them who would be discouraged by the expense, delay and disappointments incidental to raising seedlings for themselves.

LIBRARIES IN THE UNITED STATES.[1]—V.

PUBLIC LIBRARY, UTICA, N. Y.

IN the very recent competition for the Public Library, Utica, N. Y., ten well-known firms of architects experienced in the construction of library buildings were asked to compete. The conditions of competition and suggested outline plans of the two floors were drawn up by the assessor, Professor W. R. Ware, of Columbia University, New York. It has been found necessary to cut down the size of the selected design considerably, but the general arrangement



Public Library, Utica, N. Y. Mr. A. C. Jackson, Architect.

exists. The plan illustrated is the competition one without these variations. In the suggested outline-plan certain points are distinctly good, particularly the relative positions of the stack-room, delivery hall and space, and the reference and children's reading-rooms, but to obtain this nearly all these rooms have to be top-lighted to assist the side-lights — perhaps a doubtful feature, certainly an extravagant one. The children's room occupies an important place. In the conditions, its area was desired to be as the main reading and reference room. The suggested position and form of the stack-room, with its reference-space extending its whole length on each floor, is also good, the only objection being that the inside portion of the stack might be dark, depending, as it does, on the borrowed light of the lantern over the delivery-hall. Still, the advantage of having all the books within such easy reach is great.

The basement, which is about 8 feet 6 inches in the clear, is entered from the outside by an entrance from an area in the rear. The area is reached by a very wide flight of 14 steps, 18 feet wide. On either side of the vestibule are placed the public lavatories and check-rooms, and beyond are 2 flights of stairs to the delivery-hall on the main floor. All the other rooms belong to the administrative side of the building, and include a very large general work-room, machinery, heating and ventilating plant, old-newspaper files, receiving and binding stores, and janitor's quarters. There are two service-staircases and a staff-entrance. The stack does not start on this floor.

On the first floor, or main floor after passing through the vestibule, which has the librarian's public-room, 12′ 6″ x 22′, and the janitor's room of the same size, on either side, the hall corridor is reached; it is 10 feet wide, and extends from end to end, toilet-rooms being placed at the extreme ends — rooms which are hardly required at this point and necessitating waste space in the form of corridor to get to them. In the front of the building to the left is placed the newspaper-room, 26′ x 46′, and in a similar position on the right 2 special-collection rooms, one 25′ x 26′ and the other 19′ 6″ x 26′; both these are reached from the corridor. Directly opposite the vestibule is the delivery-room, 29′ x 36′, with the delivery-counter projecting into it from the stack-room. On the right is placed the children's room, 36′ x 51′, and on the left the reading and reference room of similar size; the stairs to the second floor and basement are arranged on either side between. These stairs interfere very little with the scheme desired of having these rooms practically under the control of the delivery-counter; on the other hand, whenever the lecture-room on the second floor is used, the current of people using them must become a very disturbing element to the readers. Both these main reading-rooms are lighted from the top, as well as by 3 windows at the ends. From the floor to the flat ceiling-light is 30 feet, the remaining portion of the room being 22 feet 6 inches in height. The space in each room adjacent to the windows is divided into 3 alcoves by bookcases 6 feet high. Similar cases are fitted into recessed bays on the other three sides of the room to the same height.

The librarian's private room, 10′ x 23′, is placed between the reading-room and catalogue-room, 26′ x 34′, which is placed in the far left-hand corner of the building at the end of the stack-room. In a similar position to the right are placed 2 study-rooms, both 26′ x 17′, and balancing the librarian's room is a small study-room opening out of the children's room.

[1] A paper by Sidney K. Greenslade [*A.*], Pugin student, Grissell Medallist, Godwin Bursar, read before the Royal Institute of British Architects, Monday, March 17, 1902, and printed in the *Journal* of the Society. Continued from No. 1389, page 44.

The stack-room is 65′ x 38′. The stacks are each 18 feet long and are arranged in one row. There are altogether 12 of them, containing space for 21,600 volumes on each floor, a total on the 5 floors of 108,000. The spaces in front of the stacks towards the delivery-room and at the back towards the windows are both 10 feet wide, the latter being used as a reference-room. As this is arranged so on each floor, a great number of readers can therefore be accommodated quite close to the books. This is very like the plan adopted for the seminar rooms at Columbia University, New York. Both lifts and stairs at each end of the stack are conveniently arranged. In the mezzanine floor, over a small portion at either end of the stack-room, are provided coat and lunch rooms for the staff, and study-rooms.

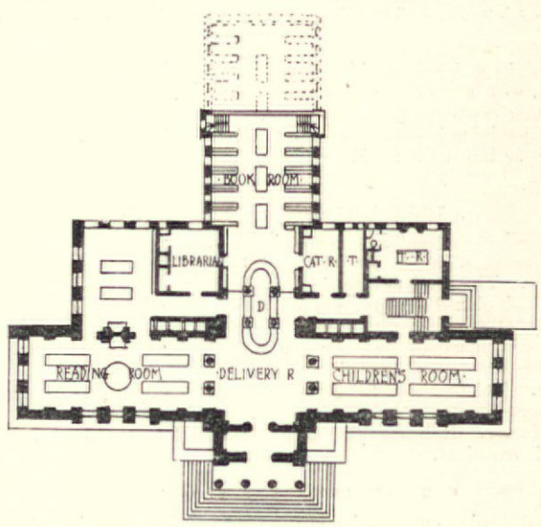
The second floor, which is level with the fourth floor of the stack, contains a large hall 30′ x 96′, a map-room 19′ x 26′, a lecture-room 19′ x 26′, two study-rooms 9′ x 36′ each, two special-collection rooms 19′ x 26′, a staff-room, with elevator, 14′ x 26′, trustees' room 19′ x 26′, and 2 toilet-rooms. The cost was limited to £30,000, and the architect is Mr. A. C. Jackson, of New York.

PAWTUCKET LIBRARY.

In the Library Building at Pawtucket, R. I., the planning is simple and straightforward. The approach is through a portico into a vestibule, and then directly into a square delivery-hall, with 2 large columns in each of the four openings leading to the main divisions of the library. Exactly opposite is the delivery-counter, enclosing a space, 25′ x 6′, having two semicircular ends, one towards the delivery-hall and the other towards the stack-room. From the attendant's desk practically all these main rooms are controlled — the children's room to the right, the reading-room to the left, and the stack-room in the rear. Originally the stack-room was arranged on the alcove system, but now it is fitted with stacks running in 4 rows lengthwise, with half-stacks at walls. They are 3 feet apart, and have 3-foot gangways across. The lighting will hardly be so successful as in the original scheme. Each floor of the stack is capable of shelving 21,000 volumes.

The general reading-room is 24′ x 55′. It is fitted with 2 rows of tables — 12 altogether — each 3′ x 5′, and seating 4. An open fireplace is placed on the inner wall, and on either side is an opening to the reference-room, 32′ x 23′, fitted with 4 round tables for 4 readers each. This room is also reached by a corridor from the delivery-hall. The children's room has also 2 rows of 12 tables, 3′ x 5′, 2 feet 2 inches high. Shelves are fitted between the pilasters along the wall of room, and the toilet-room is reached from the half-landing of the side staircase. Both these rooms are top-lighted, in addition to having windows at the front and sides. The ceiling over the delivery-hall is 36 feet from the floor, going up to a greater height than the adjoining rooms, which are 20 feet in height. The librarian's room, 20′ x 15′, and the cataloguing-room, 20′ x 12′, are placed adjacent to the delivery-desk, one on the right and the other on the left. A trustees' room and side-entrance hall and staircase balance the reference-room on the left. There is no second floor.

In the basement the newspaper and periodical room is placed under the stack-room, two circular staircases at the sides connecting



First Floor: Public Library, Pawtucket, R. I. Messrs. Cram, Goodhue & Ferguson, Architects.

them. The large rooms under the main reading-rooms are used, one as an art room and the other for special exhibits. They are fitted with special cases, swinging frames, etc.

The cost of the building was £45,000, and the architects were Messrs. Cram, Goodhue & Ferguson, of Boston.

FALL RIVER PUBLIC LIBRARY, MASS.

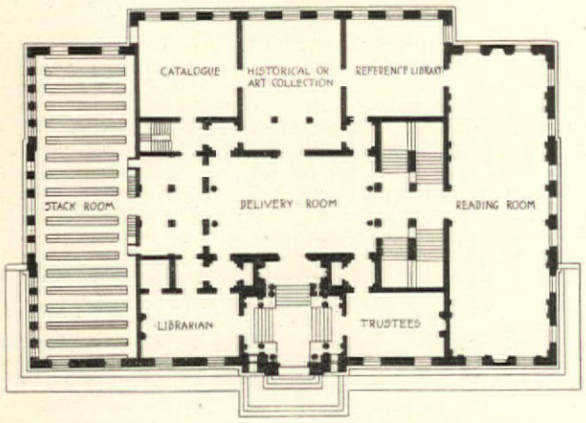
Although in one or two details the plan of the Public Library, Fall River, Mass., has been slightly altered, it is nearly the same as that illustrated, which was the one selected in the competition, but some of the rooms have been re-allotted.

The arrangement of plan is very simple. On the main floor is a large top-lighted delivery-hall, occupying the centre of the building. It has an arcaded gallery 8 feet wide on the second floor, surrounding it. To the right of it is the main staircase, very well arranged, and beyond is the periodical reading-room. To the left is placed the large stack-room, eventually to be fitted with 7 floors, and then capable of taking 325,000 volumes. Opposite the main entrance is the reference-room, occupying the position originally assigned the "Historical Collection," but one bay on either side wider. To the left of this room, adjoining the stack-room, is the librarian's room, and to the right, adjoining the periodical-room, is the card-catalogue room, with 2 stands for the card-catalogue, and 2 tables, 8′ x 4′, 31 inches high, with 4 seats either side.

There are three openings from the delivery-hall into the working space between it and the stack-room. The large central one is fitted with the delivery-counter, segmental in plan and projecting into the hall; and the two sides have straight counters (for registration and information), of similar height, 3 feet 7 inches. The stacks are 18 feet in length, in one row — 16 altogether, without the wall ones. They are 2 feet 6 inches apart. The staircase is placed centrally, and projects into the working-space, which is top-lighted. The delivery-floor level is the same as the third floor of the stack.

The periodical reading-room is well lighted on three sides. It goes up through the whole height of the building, and has a barrel ceiling, at present undecorated. The 6 tables are placed the short way of the room, and are 13 feet 9 inches long by 3 feet 6 inches wide, seating 6 either side. In the reference-room are 2 tables, 12′ x 3′ 11″ and 2 feet 7 inches high, each seating 10 readers. Oak bookcases are placed around the room, 6 feet high. The attendant's desk is at the stack-room end, next the librarian.

In the basement, under the far end of the periodical-room and the whole of the card-catalogue room, is the children's room. Beyond, under the reference-room, is a large reading-room, which eventually will be added to the children's department. The basement can be



Public Library, Fall River, Mass. Messrs. Cram, Wentworth & Goodhue, Architects.

reached by stairs from the delivery-hall, but there is also a side entrance, with a prettily vaulted vestibule on 4 gray-granite columns. Art-galleries occupy the second floor.

The public toilet-rooms are all placed in the basement.

The architects were Messrs. Cram, Wentworth & Goodhue, of Boston.

TOWN LIBRARIES. — DIVISION III.

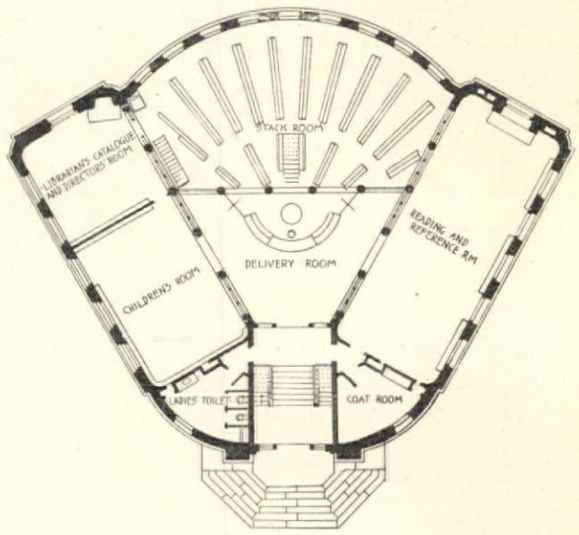
The effect of the "free access" policy, now so often adopted, is well illustrated in the plans of the 3 libraries selected under this heading. The tendency to do away with walls and substitute columns with glazed-screens between is a feature in all of them. In the East Orange and the Tacoma libraries the use of the radiating-stack, particularly in the latter, is new for such large buildings. The advantages obtained are enlarged upon in the descriptions of the libraries. The plan adopted for the Duluth Library is an unusual one, and there seem great possibilities of a development on similar lines in the future. It is not quite so well matured as the Tacoma plan, which is excellent.

CARNEGIE LIBRARY, EAST ORANGE.

The somewhat curious plan of the Carnegie Library, East Orange, N. J., is caused by the triangular shape of the site, and the result of such restriction of site has not been detrimental. In fact, it has allowed of the fitting-in of the rooms in a remarkably happy manner, and the relative positions of the two reading-rooms, the stack-room, and the delivery-room are very good. It is worthy of note that beyond the doors of the vestibule there are practically no internal walls on the first floor, but columns with glazed-screens which separate room from room. The advantage of this is very great from the control point-of-view. In the vestibule are placed the stairs to the basement, either side of a flight of 8 steps leading up to the main floor. In the basement under the whole of the stack-room is the auditorium; it is 12 feet high. The other rooms are 9 feet, and consist of store-room, repair room, janitor's room, men's toilet, boiler-room, and lunch-room for the staff.

On the first floor the delivery-room is a curiously-shaped four-sided space, right in the centre of the building. The short side, at the entrance, is 13 feet, the long one, opposite the next stack-room, is 40 feet, and the depth of the space between is 23 feet, with a varying width of from 13 feet to 40 feet.

The delivery-counter is placed in this space on the long side next



Carnegie Library, East Orange, N. J. Messrs. Jardine, Kent & Jardine, Architects.

the stack-room. The card-catalogue is arranged either side of the attendant on the counter, and beyond are turnstiles for the public to enter the stack-room. The whole of the stack-room is seen from the delivery-room. The height to the top of the columns surrounding the delivery-hall is 12 feet 6 inches, and to the flat circular skylight-lighting, some 20 feet. To the right the reading and reference room is placed; it is 20′ x 49′ 6″; and on the left is a similarly proportioned wing, in which the children's room, 20′ x 29′, and the librarian's and catalogue room, 20′ x 20′, are placed, the latter connected directly with the stack-room. The stack-room's extreme depth is 29 feet and width 58 feet, the outer wall being segmental. The stacks radiate from a centre at the attendant's desk. Against the outer wall is a gangway 3 feet wide; 5 feet separate each of the 11 stacks at this outer end, and they are about 14 feet long, and 2 feet 6 inches separate them at the inner end. There is also an inner row of small stacks, radiating from the same centre but of shorter lengths. There is room for two floors of stacks, and the height to the ceiling is 14 feet 8 inches. At present only one floor is fitted up. Each floor will contain about 23,000 volumes, a total of 46,000 in the two floors.

This is a decidedly interesting little library, and the general openness of the whole of the interior, making the control of every part from the attendant's desk easy, is a very important feature.

The cost was about £9,000, and the architects were Messrs. Jardine, Kent & Jardine, of New York.

DULUTH LIBRARY, MINN.

The Library at Duluth, Minn., is remarkably compact in its plan, and should well serve its purpose as an open-shelf library. It is in outline in the form of a Greek cross. The side-arms project very slightly. The extreme dimensions of the building are about 110 feet each way. It is practically of 2 floors, the ground floor, 11 feet in the clear, consisting of a newspaper-room (32′ 6″ x 39′) on the left of the entrance-hall, which is 19 feet 6 inches wide, and the juvenile-room (32′ 6″ x 39′) on the right. Provision is made for 2 future stack-rooms in addition to the main stack-room, which starts on this floor, one behind the children's and the other under the fiction-room. The lavatory accommodation is placed right in the centre of the building, apparently with only borrowed lights, men on one side, women on the other; this arrangement and position seem hardly successful. A packing-room below the work-room, with lift and stairs adjacent, and a store-room, boiler-room, engineer's room, etc., complete the accommodation provided on the lower floor.

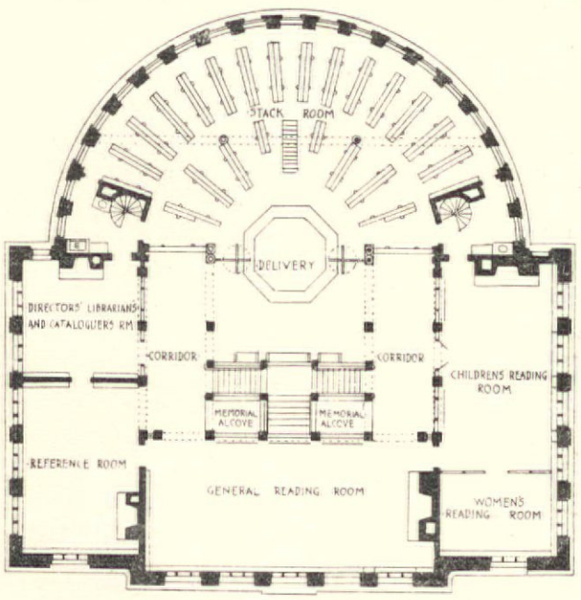
The first floor contains the principal rooms. These are all grouped around an octagonal space, 32 feet across, placed in the centre of the building. This public space is reached by the main staircase directly from the entrance vestibule, and on the side facing the entrance is the delivery-counter, with working-space behind, the whole width of the octagon, and 12 feet deep. This central octagonal delivery-hall is domed and top-lighted, and has four short sides, 8 feet wide, at the corners, and four main sides, 21 feet wide, having openings with columns between. The opening behind the delivery-space enters the stack-room, the opening on the right into the children's reading-room, and on the left into the fiction-room; both rooms are fitted with stacks. Between the children's room and the stack-room the librarian's room is placed, practically controlling the library. There is also a private room behind. At the back of the children's reading-room and opening out of it is their stack-room. The large reference-room and the general reading-room are placed to the front. A

ladies' reading-room, with lavatory accommodation, is placed just over the main entrance (which is the only entrance), and over it a board-room is placed, the only room on the second floor. At a height of 7 feet 9 inches, the glazed floor for the third tier of stacks is placed and forms a gallery finished with an iron railing just behind the columns forming the octagon. This floor occurs on the sides of the octagon opening into the fiction-room and stack-room only. The main stack-room is 32′ 6″ x 32′. The stacks are placed at 4-foot centres and two 12-foot lengths, with 2-foot 9-inch gangways, and contain 75,000 volumes. There are 3 tiers with glass floors. Tier No. 2 is at the same level as the first floor. In the fiction-room they are arranged similarly, as well as in the small room adjoining the children's reading-room. The children's room is 33′ 6″ x 26′ 6″, and is shown with 6 large tables, 11′ 6″ x 3′.

The general reading-room is 32′ 6″ x 39′, and well lighted on two sides; it is shown with 8 large tables, 3′ x 11′ 6″, and shelving around the room to window-sill height. The reference-room is 32′ 6″ x 39′, balancing the general reading-room. The general openness of this plan is very good from the control point-of-view; with the exception of the columns and small piers at the corners of the octagonal hall there is practically nothing to obstruct the view of the whole of the rooms from the delivery-desk. The architect was Mr. A. F. Rudolf.

TACOMA PUBLIC LIBRARY, WASH.

The Public Library, Tacoma, Wash., is one of the largest of the recent libraries where the radiating stack-scheme has been adopted,



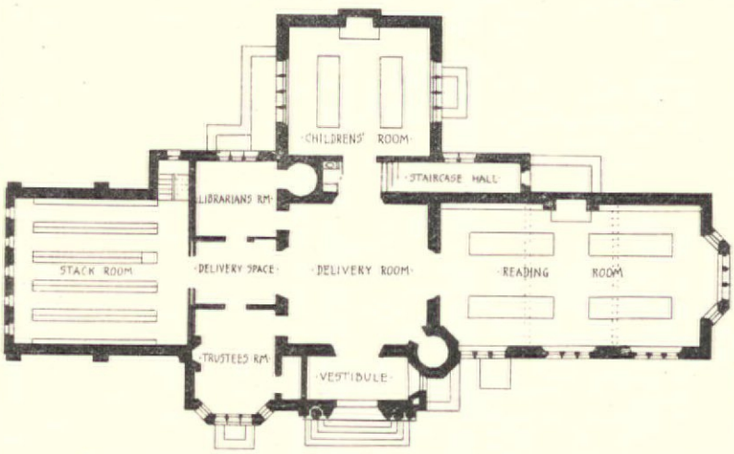
Second Story: Public Library, Tacoma, Wash. Messrs. Jardine, Kent & Jardine, Architects.

and where the maximum of supervision from the central delivery-desk is possible over every portion of the main floor of the library. The main building has a frontage of 95 feet 8 inches and depth at sides of 53 feet 8 inches; in addition, in the rear, is the semicircular stack-room. The whole consists of 2 floors.

On the first floor is placed, to the left, the newspaper-room, about 20′ x 50′; on the opposite side of the building are the boiler-room, engineer's room, and coal-room, and between them, in the front, is the large entrance vestibule, with men's and women's lavatories and a *foyer* on each side of the stairs to the main floor. The auditorium, which occupies the whole space under the stack-room, is approached from these *foyers*.

The main library floor is reached by a staircase placed centrally up from this entrance vestibule, 8 feet wide; the stairs branch (5 feet wide), half way up, right and left, reaching a wide open corridor on each side, forming wings to the central space in front of the delivery-desk. This central delivery-space is 25 feet wide, and is provided with seats.

The octagonal delivery-desk is practically in the centre of the building, having an internal diameter of 12 feet (over this space is a domed top-light), and on each side are turnstiles at the entrance to the stack-room.



Public Library, Nashua, N. H. Messrs. Cram, Goodhue & Ferguson, Architects.

The stack-room has a radius from the centre of the delivery-desk of 38 feet. There are 2 rows of stacks; in the outer row are 16 and in the inner row 8, both 10 feet long, with a 2-foot 6-inch gangway between. There are 2 tiers of them, both floors having a total capacity for shelving 44,000 books.

The general reading-room is placed to the front centrally, and is approached from the corridors on either side by large openings 7 feet 6 inches wide. It is 22 feet wide and 50 feet long, very well lighted, and having glazed openings overlooking the main stairs and delivery-space. The right wing is divided into the children's and the women's reading-rooms. The former is 20 feet wide by 34 feet 6 inches long, and the latter 14′ x 20′, a low railing 3 feet high, with gate, separating the two.

In the left wing are placed the reference-room, 20′ x 28′ 6″, and the directors', librarian's, and cataloguer's room behind it, 20′ x 19′ 6″.

The amount of floor-space lost by the radiating stack-scheme is somewhat great; at the outer gangway the distance between the stacks is 4 feet, narrowing to 2 feet 3 inches; at the inner one 4 feet 6 inches, narrowing to 2 feet 9 inches. On the other hand, the ample space next the windows would allow plenty of room for a seat and small desk to be used comfortably, and where free access is given to the stack-room a good space between the stacks becomes essential. A window between each row of stacks is provided, 3 feet 6 inches wide, so they are well lighted, the inner ones being also helped with the dome over the delivery-space and two additional skylights. The approaches to all the rooms are direct and well under control, and all the rooms are exceedingly well lighted. Ample book-shelving is provided along the walls under the windows in each room for reference. The absence of walls between the various rooms and the use of columns with glazed screens instead, and the radiating arrangement of stacks, make the control of the whole floor an easy matter from the delivery-desk. The architects were Messrs. Jardine, Kent & Jardine, of New York.

[To be continued.]

PROBABLE CAUSE OF THE VENETIAN ACCIDENT.

IN the *Edinburgh Scotsman* Mr. A. Robertson gives the most plausible explanation we have seen of the lamentable collapse of the tower of St. Mark. He gives the following summary of previous disasters, slight or grave: —

"It had been damaged by lightning, by fire, and by earthquake several times. On June 7, 1398, it was struck by lightning. In 1401, on the occasion of festivities for the Doge Michael Steno, fires were lighted on the platform and the top was burned. On October 24, 1403, the same thing happened. In 1405 the same thing happened. In 1417 it was struck by lightning and the new top of wood again burned. On June 21, 1436, all the shops around the Campanile built against it were burned. On March 26, 1511, an earthquake split its four corners. In June, 1548, it was struck by lightning. In 1565 it was struck by lightning. On July 10, 1591, an earthquake caused it to shake from top to bottom. In 1653 again struck by lightning. On August 23, 1657, again struck by lightning. On April 23, 1745, again struck by lightning, which damaged its east side severely, killing many people in the Campanile and near it. This was its last and most serious damage, although it was not till June 18, 1776, that the Republic employed the scientist Giuseppe Toaldo to put up a lightning-conductor."

Then as to the proximate cause of the irreparable disaster, he says:—

"And now comes the critical point. The Loggetta, a little marble hall, built by Sansovino, rests against the eastern wall of the Campanile. It had almost a flat roof. To prevent the rain beating against the Campanile and, running down its side, from entering this marble hall a row of slabs of stone sloping downward was inserted in the Campanile where the roof met it.

"Only last week, that is, but ten days ago, these stones were begun to be removed, as the rain was somehow getting into the Loggetta, and a lead sheeting was to have been substituted. Instead of carefully removing one stone at a time they removed half of them — that is, 25 feet of them. Not only so, but they dug through the new wall of the Campanile, that of 1745, and struck the old original wall, which they found separate from the new, and full of holes and cracks. Whilst working the old wall slipped down an inch or two. Instantly, the cut made was built up, but it was too late. On Wednesday, the 9th, it was observed that the new wall was cracked at the northeast corner, above the Loggetta, where the work was begun. On Thursday it was enlarged. On Friday it was struck across the north side

of the Campanile, sloping upward to the second window from the ground, then up to the third. On Saturday it passed behind the fourth and through the fifth. On Sunday the situation was, to use the word of an engineer, "desperate," and the Campanile was doomed. On Monday the crack visibly opened whilst we watched it, and the end came in a moment, when the whole structure sank into itself.

"Now for the responsibility. Who was responsible?

"First, the engineer of the Campanile is Signor Saccardo, who is the engineer of St. Mark's Church. But Signor Saccardo is not the engineer in charge of the "marble hall," the "Loggetta" of Sansovino. That is under the charge of the authorities who take care of other national monuments in Venice. Secondly, these authorities in repairing the Loggetta roof, for which they were responsible, cut into the Campanile, as we have seen, as one might cut into a tree they intended to fell, and this they did without consulting Signor Saccardo, who bears the care of the Campanile.

"The cutting they did, had the Campanile been in good condition, would have had no effect upon it, but as things were, it was the last straw that broke the camel's back.

"To-day the Minister of Public Works, Signor Nasi, accompanied by Signor Calderini and Signor Boito, has arrived from Rome, and an inquest will be held.

"Meantime, I have but two observations to make. First, knowing the perilous condition of the Campanile, was it right to allow travellers to ascend it as recently as Saturday night? Many, many climbed its gradient steep on Saturday, the last ever to do it. Was it right to allow thousands of Venetians and strangers to promenade under its shadows on Sunday? It was only on Sunday night the band was ordered to stop playing. On Monday morning, ten minutes before its fall, we ourselves were around and around examining and touching it. Secondly, there are too many masters in Italy. The idea of two monuments built against each other, like the Campanile and Loggetta, being under different authorities, who work independently of each other! In Venice, indeed, there are five different sources of authority in regard to such monuments — namely, the authorities of St. Mark's, the authorities for the care of monuments, the Belle Arti authorities, those who have charge of public works, and the Committee of Vigilance. Then, there is a seventh, the Artists, who often make their voices heard in favor of not disturbing the old, worn, time-eaten face of things, and who sometimes hinder external renovation.

"The Campanile weighed, it is calculated, 22,000 tons. That is the mass of débris, the pyramid of material, to be sorted and cleared before rebuilding can be begun. Subscriptions are being taken up for that purpose, and half a million francs has been already received, as promised ($100,000), but of this another time."

THE CRETAN PHÆSTOS.

LIKE other Cretan traditions, the claim of the island to have had a hundred cities is proving not altogether vain. Remains of primitive settlements, too considerable to have been villages, are coming to light at far more points of the Cretan coast than bear a name in classical atlases. There are half a dozen such in a part only of the eastern half isle, and the recent exploration of two among these supplies a key to the rest. One now suspects a "Mycenæan" site in every larger plain of the periphery. So far as searched at present, these towns show little or no sign of having continued into the historic period. Their civilization was blotted out with the "Mycenæan" domination. The succeeding class of remains is found for the most part higher up inland, on difficult heights or in remote gorges. The coastal plains were secure no longer. An age of seafaring and communication between ancient seats of luxurious life had given way to one of local and jejune development. But why and how we may only guess.

The crown of the great Cretan civilization was in Mindan Knossos. No other site in the island had furnished, or is likely to furnish, evidences of so high artistic achievement. But there is at least one notable site better preserved. Knossos, owing to its revival in later epochs and the proximity of its site to the mediæval capital of Crete, has suffered wreck and plunder beyond other sites. Much knowledge and more imagination are required to invest with full significance its "shorn and parcelled ruin," which, lying low in a featureless valley, conveys no immediate impression of magnificence. One must study its cracked and faded fragments of fresco, and look narrowly into the work of its reliefs and stone vases, to realize why it claims to rival Mycenæ in interest. The house must be reconstructed from its furniture, rather than the furniture from the house.

The ordinary visitor, not a specialist, will, therefore, prefer the ruin at Phæstos, on the south of the island, the full revelation of which has certainly been the sensation of the past spring. When Professor Halbherr announced in 1900 that he had begun upon a lesser Knossos no one expected that he and his Italian colleagues were to find, in the event, a palace more uniform, complete and imposing. What they have now laid bare stands alone in Crete as a spectacle. Even those fresh from the Mycenæ walls and the treasury of Atreus, or even from Egypt and Syria, must admire the broad staircases and majestic courts of Phæstos, all on so intelligible a plan and preserved to a point which excites without overtaxing imagination. The ruin covers a promontory of rock. Far below, the greatest of Cretan plains stretches to Mt. Dicte in the blue distance. Ida hangs right over the site and through a gap in the screen to the west show the snows of Sphakia, all three high masses of the Cretan relief being visible from this one point. In so superb a setting it is the more pity Phæstos should be so difficult of attainment. It may, indeed, be reached in an hour from the sea, but it is from the stormy, harborless Libyan Sea. A steamer that had landed its passengers in the sunrise calm at Dybaki would often be unable to reëmbark them at noon. One must ride, therefore, from Candia, making a three-day expedition, which will include also Gortyna; but the days are long and the paths are rough.

The palace of Phæstos is contained in a vast rectangle, obvious at first sight. There had been an earlier structure, but the building now revealed is of the character and period — that of the acme of the Mycenæan age in Crete. The visitor, approaching from the north, sees from a terrace the ruin below distinguished into three main quarters. On his left a broad stairway descends to a spacious paved court, containing an altar and tiers of stone seats, built up against the rock, evidently to hold an assembly. Flanking this on the east and raised high above it is the main building, entered by a truly majestic flight of steps, extending the full width of the fine pillared hall at their head. But the entrance from without is from the opposite side, where a second and larger paved court stretches to the brink of the precipiece. Thence is admittance not only to the pillared vestibule and the main hall, but to a doubled rank of galleries, and a maze of small chambers to southward, which form the third quarter. This great court, round which the walls and doors are admirably preserved, vies with the region on the west, where the two main stairways meet, as the best point-of-view on the site. To one standing in it, the uses of the various blocks about it are manifest. Here were the living and sleeping rooms of men, there of women. Their common hall of assembly occupies half another side; the store galleries for the produce of the plain fill the other half. In the chambers to the south they bathed, worshipped and lodged their retainers and their beasts.

All this is constructed of an excellent limestone, which has retained its sharp and square outlines, while the Knossian gypsums have crumbled and collapsed. The general impression, therefore, is the more convincing. But in details, the inferiority of Phæstos is unquestionable. The elaborate frescos, the sculptured friezes and the delicate plaster-relief of Knossos were never here. Phæstos was provincial. It could command good stone and good masons, but not the materials or the men for the more subtle crafts. The noble shell was decorated only in the rudest manner, and its ruin is not comparable to that of Knossos as a museum of art. On its plastered walls appear none but conventional patterns of a primitive sort; the only sculptured thing of any note yet found is a fragment of shell; the clay vases are interesting, but of common ware, and the fine stone vases have not come to light at all; trinkets in the precious metals or stones have not been found, and two small tablets make a poor show beside the immense clay library of Knossos. Indeed, all the smaller finds are conspicuously wanting. For example, clay impressions of lost signet-intaglios, a most valuable class of which Knossos has yielded to Mr. Evans scores of admirable examples, and Zakro some hundreds to me, remain unrepresented among the Italian discoveries. —*D. C. Hogarth, in the London Times.*

LONDON DOCKS.[1]

AT London the rise and fall of the tide is very great, the mean rise and fall being 17½ feet at London Bridge. At various points along the river piers are built out, at the ends of which the coastwise steamers lie to receive and discharge their cargoes. These piers are too narrow to permit of mooring the whole length of the vessel directly to the ends of the piers, so mooring-buoys are placed in the river above and below the piers, and to these buoys the mooring-lines are made fast. All along the river below the Victoria Embankment, and also on the Surrey side, the warehouses are built at the water's edge and steamers and barges are brought alongside and lie there on the bottom while their cargo is discharged into the warehouses by long-armed cranes which are attached to the faces of the buildings.

In some places the bed of the river is prepared and levelled above the level of low-water mark, so that the flat-bottom barges can lie there when the tide recedes without dropping too great a distance below the level of the wharf. At various points in the river are placed mooring-buoys, to which steamers are made fast, stem and stern, to prevent their swinging while their cargo is discharged over the side into lighters, which are then floated up and down the river to the various warehouses. These lighters, or scows, are also taken into the various docks and loaded from steamers or vessels lying there, and then are taken out again into the river to the warehouses, railroad-stations and canals.

Docks similar to those at Liverpool are built on both sides of the river at various places. Some of the oldest, as the London and St. Catherine's Docks, are just below the Tower and are very massive, having heavy stone and brick warehouses built right on the quay-line. Below these, on the same side of the river, are the East and West India Docks, which are located on the inside of a bend in the river and have openings into the river at both ends. Below these again are the Victoria and Albert Docks, and at the mouth of the river are the new Tilbury Docks, which are the only ones into which

[1] Extract from a paper by F. W. Hodgdon, read before the Boston Society of Civil Engineers and published in the *Journal of the Association of Engineering Societies.*

the largest steamers can enter, the tidal basin having a depth of 23½ feet at low-water spring-tides and 42½ feet at high-water spring-tides. The depth on the outer sill of the lock leading to the closed dock is 1½ feet less. The Victoria and Albert Docks accommodate the larger part of the Peninsular and Oriental steamship lines, as well as many others. There are large cold-storage warehouses for receiving and storing frozen meat, and there have just been installed at the Victoria Dock small grain-elevators for transferring grain from barges to cars.

Some of the dock-walls in the Victoria Dock are constructed of vertical cast-iron I-beams, with webs and flanges over 2 inches thick, the spaces between the I-beams being filled-in with brick arches. There are also a few pile-piers built of square timber.

The walls of the Albert Dock are constructed wholly of concrete except at the entrances, where they are faced with brick. Very little is now being done in the London docks in the way of improvement, and I was told by the engineer at the Victoria and Albert Docks that it was almost impossible to get the authority to make the really needed improvements.

At the West India Docks one of the large entrance-locks was being reconstructed, the arch of the invert being taken out and replaced with one having a greater radius in order to allow modern vessels with flat bottoms to enter, the depth of water at the sides being increased about 4 feet; at the same time the lock is being lengthened and an additional pair of gates placed at the inner end. In order to carry out this work a coffer-dam of timber was built on the apron outside the entrance-gates, and at the inner end, in the dock itself, a circular coffer-dam was being constructed of Southern-pine timber, each pile constructed of two sticks 12 inches square bolted together. The piles thus made, being driven close together in the dock, form a semicircular wall 2 feet thick around the inner end of the lock. These piles were driven as close together as possible in sections of ten piles each. When one section was driven a space of about 10 inches was left and then another section of ten piles was driven. This was continued until the whole distance had been covered. Then, by the aid of divers, the exact space between each two sections was measured and a pile, cut slightly larger than the space to be filled, was driven into it, thereby wedging all the others together.

To strengthen the top of the coffer-dam, a horizontal timber arch 8 to 10 feet thick and 12 inches wide, made of planks 3 inches by 12 inches, was built against its inner face. Between this and the bottom it was proposed to put in additional bracing by the aid of divers. Just before my visit, the dam had been completed with the exception of some of the under-water bracing, and an attempt was made to pump it out. When the water had been lowered about 12 feet, the dam gave way near the middle, and at the time of my visit it was being reconstructed with the intention of putting in additional under-water bracing. In placing the new invert in the lock, sections 5 to 6 feet wide are first cut out of the old invert and a new invert of concrete built in place; then the intermediate sections are cut out and sections are built-in between the sections previously constructed. The entrance at which this work is being done is 55 feet wide.

On the opposite side of the river is another large system of docks used largely by sailing-vessels.

There is a large passenger-traffic on the river in small paddle-wheel steamers which run up and down the river from Westminster Bridge and Greenwich every half-hour and other steamers which run much oftener to intermediate points.

Along the banks of the Thames are many dry-docks opening directly from the river. They are large enough to accommodate the ordinary sailing-vessel, and some are of considerable size. The sills are above the plane of low water, and after vessels are placed in them and the gates are closed, the docks are emptied by allowing the water to flow out as the tide falls, the sluice being closed at low water, and after the vessels have been cleaned or repaired the water is allowed to enter at high tide and the vessels are floated out. This makes very cheap dockage, no pumping-plant being required.

At Liverpool some of the older dry-docks, opening from the wet-docks, are equipped in a similar manner by having sluices built through the walls of the main dock out into the river; but all the larger and more recent docks are built with pumping-plants, the Canada Dock, the largest now in operation, being equipped with pumps which will empty the entire dock in 1½ hours. This method of operating dry-docks, of course, can be used only where there is a considerable range of tide, as there is in Great Britain.

THE PORT OF LONDON.

IN connection with the foregoing extracts the following, from a paper on the Port of London by the Right Honorable Earl Egerton of Tatton in the *Nineteenth Century* for July, will be found of interest: —

London is not the only port affected by the recent growth of the enlarged ports of Hamburg and Antwerp. The French are alarmed at the decadence of their ports, and an article appeared in the *Petit Marseillais*[1] commenting on a report from the Antwerp Chamber of Commerce, from which I glean some important facts. Since the abolition of the Scheldt dues threw open the Port of Antwerp it has been constantly progressing: from a port-tonnage of 3,063,825 tons in 1880 it had increased to 4,506,277 tons in 1890, to 5,322,262 tons in 1895, and to 6,872,848 tons in 1899; it is at this time the third port of Western Europe. This is a result of which the Belgians have reason to be proud. But the principal cause is that Antwerp has become more and more a, so to speak, supplementary port of the German Empire; the carrying of emigrants to America is very important, and it is especially from the American coast that the commercial and maritime increase comes. Napoleon wished to make Antwerp a pistol pointed at London, the heart of England; and does not the great Belgian port somewhat play this part to-day?

"But the progress of Hamburg is still more significant. In 1880 Hamburg was only the fifth port of Western Europe, and came after Marseilles, with a port-tonnage of 2,766,806 tons; in 1899 Hamburg had risen to the second rank, and closely presses London, with a port-tonnage of 7,765,950 tons.

This remarkable progress is due to three causes — the general development of Germany since the war of 1870–1871; the marvellous network of communications — railroads for light and costly goods, canals for heavy goods — which border upon Hamburg; and, lastly, the initiative spirit and the activity of the Hamburgers.

Another port whose progress is still more marked, and which although situated on Dutch territory may perhaps be considered as a sort of annex to the German ports, is that of Rotterdam; the seventh in 1890, it is to-day the fourth, and has considerably distanced Marseilles, going from 1,681,650 tons to 6,323,072.

The Port of Marseilles from the fourth rank in 1880 has fallen to the sixth rank in 1890, though the amount of its tonnage has always slowly increased: 2,769,047 in 1880 to 3,458,914 in 1890 and 4,699,168 in 1899.

The foreign trade of London and Liverpool is compared with that of other foreign ports in the following table. The figures of London and Liverpool are taken from the Board of Trade Returns for 1900 for vessels with cargoes and in ballast, and those for foreign ports from the *Petit Marseilles*: —

	1880.	1899.	Increase.	Position as a port.	
				1880.	1899.
London	5,970,341	9,437,950	3,467,609	1	1
Liverpool	4,913,324	6,152,187	1,238,863	2	5
Antwerp	3,063,825	6,872,848	3,809,023	3	3
Marseilles	2,769,047	4,699,168	1,930,121	4	6
Hamburg	2,766,806	7,765,950	4,999,144	5	2
Havre	1,969,000	2,175,000	206,000	6	8[1]
Rotterdam	1,681,650	6,323,072	4,641,422	7	4

[1] Now below Bremen.

One of the great drawbacks to the Port of London is the want of despatch in the unloading of cargo and the consequent loss to the shipowner.

Sir Alfred Jones states that while London costs about the same as Liverpool and Avonmouth, the despatch is about five times as bad in the case of a large vessel in London.

The usage of the Port of London is, that if required by the consignee the goods have to be delivered not merely on the quay but to the consignee's barge. There is great difficulty in doing this with the mixed cargoes that large steamers now convey, and it is cheaper for the shipowner to pay 1*s.* 6*d.* or 2*s.* per ton to get the sorting done on the delivery made on the quay than to suffer delay and loss consequent on the ship discharging overside to craft.

Sir Thomas Sutherland considers that shipowners ought to be able to discharge their ships in dock, on to the dock-quay entirely, as they do in all great ports, and that the subsequent handling of goods, if they are to be taken away by barges for the convenience of consignees, should be at the cost of these consignees; but in the present state of the dock-plant and of their warehouses, which are simply ground-floor sheds, it would be impossible to discharge *in toto* the large cargoes which are now brought into the docks.

It is difficult to realize how great is the capacity of these large ships. Mr. Douglas Owen points out that the cargo of a vessel, not by any means of the largest size — viz, of 8,000 tons — would require 1,000 truckloads or 50 trainloads to transport it; how can it be sorted, whether bags, cases, or packages, except there is a shed into which it can be lifted by hydraulic power, with five or seven stories to hold different classes of goods such as were recently erected in the Port of Manchester. It is in these provisions, which are supplied in the newest Port of Manchester, that London is deficient, and in which the modern ports of Antwerp or Hamburg have the advantage over London. In Manchester a line of railway and road for wagons run into the sheds so as to save as much as possible the cost of handling the goods. Alongside timber ships a floating platform is placed on which the timber is stacked and moved to any part of the port, and the vessel is discharged on both sides at once, on to the platform and quay.

EARL GREY AND THE BRITISH LION. — Writing to the Honorable Secretary of the Rhodesia Memorial (1896) Fund, at Bulawayo, Earl Grey suggests some modifications in the design of the proposed monument. One alteration his Lordship desires to see is the removal of the assegai from the lion's breast, as he "does not approve of the British lion submitting to this indignity." It would, he maintains, be more in keeping with the history of the country if the lion stood upon a broken assegai, thus symbolizing the establishment of the Pax Brittanica in Rhodesia. — *St. James's Gazette.*

NOTES & CLIPPINGS

BUILDING-LABORERS SCARCE IN CHICAGO. — Chicago building-contractors are hampered in their business at present by a shortage in the supply of laborers, according to the Hod-Carriers' and Building Laborers' Union, which acts also in the capacity of an employment-bureau. The minimum wage paid for this class of work now is $2.80 a day, and contractors in need of men have run the price above the union scale. Union hod-carriers in many cases are getting 37½ cents an hour, while the union scale is but 35 cents. — *N. Y. Times.*

RESTORATION OF CLIFFORD'S TOWER. — The grant of £3,500 which the Treasury has just promised towards the cost of restoring the historic Clifford's Tower of York Castle is but a reasonable recognition of the national character of the work. Standing high upon the great Castle Mound, Clifford's Tower looks the part of beetling donjon to a nicety. The tradition attaches to it of having been the scene of the massacre of 1190, when some hundreds of Jews and their families shut themselves up either within its walls, or in other portions of the castle, in the vain hope of escaping the fury of the citizens. At present it is little more than a shell. For some reason or other the garrison which the son of the vanquished of Marston Moor maintained in the massive old keep was unpopular with the citizens, and one fine day the magazine blew up, and Clifford's Tower was an empty shell. — *London Standard.*

ELECTROLYSIS AND PIPE-SYSTEMS. — The question of electrolysis in pipe-systems and the proposed prevention of the action by means of insulating-joints, recently printed in the *Evening Post*, has brought forth a number of objections from those interested in the piping-systems. In response to these, George T. Hanchett has written to the *Electrical Review* to refute the arguments used. He declares that there are plainly two ways of stopping the electrolysis, one being to prevent the electric current from leaving the pipe which it has sought as the path of least resistance on its return to the power-house, and the other to keep it out of the pipe altogether. The proposed plan, he says, to make the pipe-return a poor conductor, is not to make the metal immune to electrolysis, but to keep the current out of it. The first plan, to prevent the current from leaving the pipes, which would also prevent electrolysis, could be carried out by making the pipe-line an absolutely continuous metallic structure, and connecting it solidly to the return feeders at all points where current tends to leave it. This, the writer claims, is rarely satisfactory, as the current distribution is continually changing with the position of the cars. The other plan, that of breaking up the piping-system so thoroughly that currents would not enter it, is believed by Mr. Hanchett to be a complete protection, and of much more worth than the first proposition. He says in conclusion: "Let us for a moment revert to the facts in the case. Electrolytic action is a simple and quiet chemical decomposition, taking place very much like the dissolving of metal in an acid, and without pyrotechnics of any kind. It is proportionate to the volume of current and to the time that it flows. It will attack any conductor, either poor or good, at the point of leaving if the conditions are such as to invite electrolytic action. It can be effectively checked by making *nil* the volume of current flowing. This can be done by thoroughly breaking up the electrical continuity of the piping-system. A partial attempt to do this will be worse than to leave the metallic continuity intact, and the experience and judgment of most of the newspaper communicants seem to be drawn from such cases, which are frequent in practice. If the conductivity of wet grounds were nearly that of cast-iron, it is probable there would be little choice between the iron pipe and the ground, which would make the construction of insulating-joints difficult. Unfortunately, the most conducting loam saturated with salt water measures about 20 ohms to the cubic yard, while a cubic yard of cast-iron, especially alloyed for high resistance, has a resistance of about .0000011, making the conductivity of cast-iron almost twenty million times as great as that of moist conducting earth."

A USE FOR THE PEAT-BOGS OF NEW YORK. — As the anthracite-coal miners' strike continues and the price of coal advances the people begin to look about for a substitute fuel. Dr. Wilson S. Pettit, of Lockport, who has investigated the fuel question to a considerable extent, says that $10, or even $8, per ton of anthracite coal this winter will mean that many people will not be able to buy a sufficient amount to keep warm and for domestic purposes. Unless a cheaper substitute fuel can be found, he thinks there will be great suffering, provided the strike is not settled very soon. Dr. Pettit has suggested that peat be substituted, to a certain extent at least, for anthracite or bituminous coal. It is not generally known that peat abounds in Western New York. On the bog-lands of Orleans, Erie, Monroe, Niagara, and Genesee counties there are immense deposits of peat as rich as any found in Ireland, Scotland, or Germany. The fuel is quite good, but because of the manner of combustion is not equal to either kinds of the most commonly used coal. It is suggested, however, that peat, treated with petroleum by an inexpensive process, would furnish a fuel equal in heat-producing powers to anthracite, and in many respects superior to hard coal. — *N. Y. Times.*

TO INCREASE INCANDESCENT-LAMP EFFICIENCY. — An ingenious system of increasing the general efficiency of incandescent lighting was recently described before the French Academy of Sciences by G. Weissman and André Blondel. The authors state the well-known fact that incandescent-lamps with carbon filaments cannot be made below 5-candle-power for pressures of about 100 volts, since the filament required is smaller than can be commercially manufactured and handled. They point out that the efficiency of a carbon filament also depends to a large degree upon the size and candle-power of the lamp. For example, speaking of commercial efficiencies and 110-volt lamps, the 32-candle-power lamp will show 3 watts, the 50-candle-power lamp 2.5 watts, and the 100-candle-power lamp 2 to 1.8 watts efficiency. It appears, therefore, that large filaments show higher efficiency in luminous output than the smaller ones, and also possess greater steadiness in burning on account of what may be called their heat inertia. The economizer system suggested consists in putting a very small transformer in the circuit of each group of lamps, so arranged that its primary is cut in or out by the lighting-switch. For example, in place of using 10-candle-power 110 volt lamps with fine filaments which consume 4 watts per candle-power, lamps of 22 volts and 10-candle-power may be installed, consuming only 2.5 watts per candle-power. At 22 volts lamps of 1-candle-power may be made very satisfactorily. The small transformer may be made of very high efficiency, going up to 97 per cent for sizes up to 300 watts. They are always worked naturally at full load, and as their primaries are cut out when the lamps are extinguished, cannot produce phase displacement or all-day core losses. It is stated that several thousand lamps have already been installed in Paris on this system, and during the 8 months they have been in operation have given generally excellent results. — *N. Y. Evening Post.*

WARNINGS FOR USERS OF ELECTRICITY. — In the Report of the National Board of Fire Underwriters are recounted these two very instructive stories: The destruction of one house nearly resulted from the overheating of an electric flatiron. The appliance was hung upon the wall when not in use. While in that position a child turned the switch so that the current was turned into the iron. After a time the heat became so intense that it communicated through the plastering to the lath and studding, which were finally ignited. The smoke was discovered by a servant on the third floor in time to avert serious loss. A $35,000 loss occurred during a thunder-storm when lightning temporarily disabled service-wires furnishing current to a supply-store. One of the employés going to the second floor to show some merchandise, turned the key of a lamp attached to an extension cord. As it did not work he carelessly dropped the lamp on top of some clothing. When the current was turned on a fire was started in the stock with very disastrous results. — *Exchange.*

THE TOWER OF ST. MARK AND PROFANE PRIESTS. — Some centuries ago, but discontinued in 1518, there was a curious iron cage, quite exposed to the elements, hung to the side of the tower about half-way up, into which swearing priests were locked for longer or shorter periods, their food being let down by ropes. The bells were 5, now buried in the débris at the bottom, and each had its own name, their music being as familiar to the Venetians as Bow Bells to London. Their ceasing to ring makes the silence of this silent city all the more marked. — *Pall-Mall Gazette.*

NOTES AND CLIPPINGS. 72

THE eleventh Part of "*The Georgian Period*" is in press, and we now have only to select the material for the twelfth, and final, Part of a publication that has received from critics and reviewers an unusual amount of praise and remarkably little in the way of blame. When an undertaking of this kind is nearly complete, it is easy not only to know what matter has been gathered and used, but, conversely, what matter has not been used, presumably because it was unknown to the editor or for some reason inaccessible to him. It will be a misfortune if desirable and accessible material should not find a place in a work which to some degree is comprehensive and thorough, and hence we will make one more appeal to our readers to let us have the use of any illustrative material or historic and architectural data which, because of their real value, should not be omitted from the twelfth, and final, Part, already in an advanced state of preparation, but having still enough elasticity to take in more material than is at present in sight. At one time or another many people have notified us that they already had photographs or drawings of interesting and unpublished buildings, or else that they could easily procure them, and though frequent reminders have failed to make some of these promised treasures materialize, the proffers are surely a proof that there is abundant material to be had, if only memory, convenience and good-will could be brought to work synchronously.

AMERICAN art, as well as the American public, has suffered a great loss in the death of General Charles Greely Loring, for many years Director of the Boston Museum of Fine Arts. General Loring was a noble example of that class of citizens, peculiar, perhaps, to republics, who can serve their country in various capacities, and serve it well in all. Born of a distinguished and intellectual family, he interested himself, even in his college days, in the study of antiquity, and pursued his researches in a modest way after his graduation. At the breaking out of the Civil War he abandoned his peaceful occupations, and entered the army as Assistant Inspector-General of the Ninth Army Corps. He was sent immediately to the front, and participated in the great battles of the Wilderness, Spottsylvania and Bethesda Church, receiving his brevet as colonel for gallant and meritorious services. A few months later he was brevetted brigadier-general for services in the campaign in Eastern Tennessee; and, in 1865, he was made major-general by brevet. After the conclusion of the war, he made a short trip to Europe, and soon after his return, found congenial occupation in assisting in the arrangement of the Way Collection of Egyptian antiquities, which had just come into the possession of the Museum of Fine Arts. The skill and learning which he displayed in this work excited the grateful admiration of the authorities of the Museum, and he was elected a member of the Board of Trustees. Four years later he succeeded the late Martin Brimmer as Director of the Museum, and held this office until last May, when his feeble health compelled him to retire from his post. As Curator and Director, the administration, not only of the collections of the Museum, but of its finances, devolved upon him, and the burden of making a small and uncertain income cover the cost of making the Museum the public benefit which its founders designed it to be was often a serious one. Without his energy and resource, and the tact with which he conciliated all classes of citizens to the support of the Museum of which Boston has so much reason to be proud, some of the years of his administration would have been gloomy ones. It is said that his anxieties on this account were in a great degree responsible for the failing health which compelled him to give up his task at an age when a man of so much force might count upon several years of usefulness; and it is significant of the determination with which he carried out his duties as long as he could that hardly three months elapsed between his resignation and his death.

WE mentioned, some weeks ago, that suit had been brought against the Boston Elevated Railway Company, to recover damages for injury done to an estate abutting upon a street in which the railway is built, by the noise incident to the movement of the trains. This claim has been energetically contested by the railway company, on various grounds, but principally on the ground that the charter of the company provided that it should pay damages to abutting owners for obstruction of the street, and for deprivation of light and air, thus, by implication, excluding claims for injury from noise. This important case has now been decided in the Superior Court, the Chief Justice delivering an admirable opinion, in which he points out that, even if the Legislature were disposed to do so, it could not authorize a corporation to injure any citizen, or deprive him of any of his rights, without compensation; and that the question was whether the noise incident to the operation of the railway caused injury of a kind which, like the deprivation of light and air, entitled the sufferer to recover definite damages. In regard to this, the Court was of opinion that the estate of the petitioner had suffered injury, beyond any benefit that the location of the railway conferred upon it, to the extent of two thousand dollars; and that half of this injury was chargeable to the noise made by the trains. Naturally, the railway company, which is hardly likely to view with complacency the prospect of having the damages doubled in the compensation cases now pending, has asked permission to appeal to the Supreme Court; but it is said that the decisions of Chief Justice Mason are seldom reversed in the upper court. There is no doubt that the Boston Elevated Railway is very noisy. The structure is open, to allow as much light as possible to go through it; and this circumstance adds materially to the noise incidental to the passage of trains. Either for this reason, or for some other, the actual injury done to abutting estates, as shown by the loss in rental value, and the diminished prices obtainable in case of sale, has been very great along the line of the Boston Elevated road; and it may be found necessary, in order to save heavy damages, to devise some means of operating the trains more quietly.

THE National Arts Club of New York issues an appeal for American subscriptions in aid of the rebuilding of the Campanile in Venice, basing its appeal on the fact that for many generations Americans have received pleasure and benefit from the art and architecture of Venice, and that both public and private collections of works of art in Italy have long been freely opened to American students. Although Italy is poor, and Venice is poorer still, it is now said that the Venetian Government is disposed to attempt the rebuilding of the Campanile from its own resources, without calling for assistance from outside of Italy. Every one will commend the courage displayed in this resolution, which recalls the Venetian spirit of former days; but Americans might make a gift to the Venetians, to be used indirectly in aid of the rebuilding, which could

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

be accepted with perfect propriety, and would do much to endear the American name to the reserved and home-loving people of Venice. Every one may not know that, in 1777 or 1778, the new-born Republic of the United States of America, through Dr. Benjamin Franklin and its other delegates in Europe, proposed to the Republic of Venice a treaty of alliance and mutual support. The Venetian Government had just then too many cares on its shoulders to be disposed to assume any additional responsibilities in connection with a revolutionary Government four thousand miles away; but the feeling in Venice seems to have been favorable to the idea of intimacy with the young Transatlantic nation. Since that time, while Venice has seen its political and commercial importance almost disappear, the country which, a hundred and twenty years ago, was the only other commercial republic in existence, has risen to be the greatest power in the world; and so good an opportunity for the Americans, without offending the pride of a people whose commonwealth was a thousand years old before Columbus sailed from Palos, to show courtesy and generosity to the citizens of a community which favored them when they needed friends, may never occur again. Those of our readers who are disposed to join in the gift may send checks or money orders, payable to the order of Spencer Trask, Treasurer, either to the National Arts Club, New York, or to Spencer Trask & Co., 27 Pine Street, New York, giving at the same time their own name and address.

THE New York Municipal Art Society is finding its hands tolerably full in its endeavors to fulfil its duties under the new city charter. Recently, a design for a proposed street-sign was submitted to it, and approved. Nothing more was done for a time until an advertisement appeared, calling for bids for street-signs for the Borough of Manhattan, in accordance with a certain design. These bids were received and opened, but, before the contract was awarded, the Municipal Art Society learned that the design upon which the bids were invited was not that which it had approved. As the city charter absolutely requires the approval of the Society in such cases, the attention of the President of the Borough, Mr. Cantor, was called, in a letter which can hardly be too highly commended for its courtesy as well as firmness, to the fact that a contract awarded without such approval would be void. As the approval of the Comptroller is also required for municipal contracts of all kinds, and that official is now in Europe, nothing will be done about the matter before his return; but it is probable that, in view of the circumstances, he also will withhold his approval, so as to avoid involving the Society, which has done so much for the city, in any controversy, and that new designs will be made.

MEANWHILE, Mr. Cantor, who has the interests of his borough very much at heart, earnestly urges the appointment of a Commission to prepare a general plan for the improvement of New York, as has been done for Washington, and says that, if Mayor Low does not appoint such a Commission for the whole city, he will himself appoint one for Manhattan. Such a Commission would have plenty to do. Mr. Cantor mentions the "island" which has just been placed at Twenty-third Street and Broadway, giving due credit to the Municipal Art Society for its generous and enlightened aid in decorating it; and says that a similar island has already been provided for in Fourteenth Street, near Union Square; but, for the future, he thinks that such works should be placed in charge of a Commission of the sort that he proposes, which should study the conditions, and decide where future islands should be placed, and how they should be decorated. With these modest works to attend to, besides the greater schemes of viaducts, bridges, terraces and so on, which are already in contemplation, a good Commission, such as Mayor Low or Mr. Cantor would appoint, might almost revolutionize the appearance of New York in a few years, and it is to be hoped that the project will be carried out.

THE Department of Architecture of Harvard University has just issued its annual announcement, which has a special interest, partly on account of the courses in what may be called pure æsthetics, which accompany the more strictly utilitarian studies, and are, so far as we know, peculiar to the Harvard School of Architecture. It is, perhaps, unnecessary to say that the Harvard curriculum is thoroughly artistic, the student, as the announcement observes, being required "to devote all the time he can possibly give" to the work of the classes in design, besides drawing and coloring from the round and the life, and modelling in clay, for recreation; but, in addition to these things, a course is given in the Theory of Design, by Dr. Denman W. Ross, with an assistant, which appears to resemble in scope Garbett's little book, familiar to older architects, and to afford valuable and interesting suggestions to students of sufficient intellectual capacity to appreciate it. Dr. Ross, so far as can be gathered from the synopsis in the Announcement, begins by taking a spot of paint as a term of expression, and showing how its suggestions are varied through abstract form, symmetry, color, tone and harmony, comparing the appeal of pure design to the eye with that of music to the ear. This form of art is contrasted with that which suggests by imitation, or representation, and the influence of one on the other; and the "undeveloped possibilities of pure design" are treated in what must be an admirable course, which we wish might be available to architects of maturer years. A course in some ways related to this is given by Professor Santayana, a man, we need hardly say, distinguished throughout the civilized world for his brilliant essays on æsthetic philosophy, on the Philosophy of Art, with a survey of the æsthetic theories of Plato and Aristotle, Lessing, Schopenhauer and Hegel. This course is devoted more particularly to tracing the relation of æsthetic to scientific and moral matters, rather than to the development of the sense of beauty and the power of imagination which forms the object of Dr. Ross's course; but it should be not the less a very stimulating and strengthening exercise for students of high capacity.

THE city of Paris, after long discussion, has adopted an official scale of fees to architects for public work, which has an interest for the profession everywhere. As the municipality is likely to expend many millions of dollars in public buildings within the next few years, it has adopted a reduced fee for the most important commissions, making up for it by allotting a compensation larger than the traditional five per cent for the less important ones. As it now stands, the official scale allots to the architects of buildings costing more than one hundred and sixty thousand dollars a commission of only four per cent on the expenditure; for those costing from one hundred and twenty to one hundred and sixty thousand four and one-half per cent is paid; five per cent for those from eighty to one hundred and twenty thousand; five and one-half per cent for those from forty to eighty thousand, and six per cent for all buildings of less cost than forty thousand dollars. The Administration reserves, however, the right to increase or diminish the fee, according to the character of the structures concerned.

THE preliminary competition for the Liverpool Cathedral occupies much of the attention of writers in the English professional journals. Strictly, the competition was simply a general invitation to architects to submit such drawings, or other evidences of their skill in church design, as might enable the Cathedral Trustees to make a selection for invitation to the final competition. It may be imagined that many architects of the highest reputation would not care to enter such a contest, particularly as the Trustees did not bind themselves to make their selection only from the participants in the first competition; but a large number of well-known names were included in the list, among them being those of R. W. Gibson and Cram, Goodhue & Ferguson, who, we may be sure, have done credit to the skill of American architects in church design. The original invitation appeared, at the time, to call only for work done previously by the competitors, but many of the Englishmen understood it differently, and sent in actual designs for the proposed building. According to the English journals, most of these were not extremely successful, and it is likely that the building will be carried out by some one whose name has not yet been connected with it.

THE meanest thief recorded in history seems to have been discovered in New York, in the shape of a young man who goes through the halls of tenement-houses, breaking off the gas-fixtures, and carrying them off to sell for old brass, of course leaving the gas escaping in streams from the broken pipes. Fortunately, this youth has been captured, and it is to be hoped that his punishment may be such as to deter any one from imitating his exploits.

LIBRARIES IN THE UNITED STATES.[1]—VI.

BRANCH LIBRARIES.

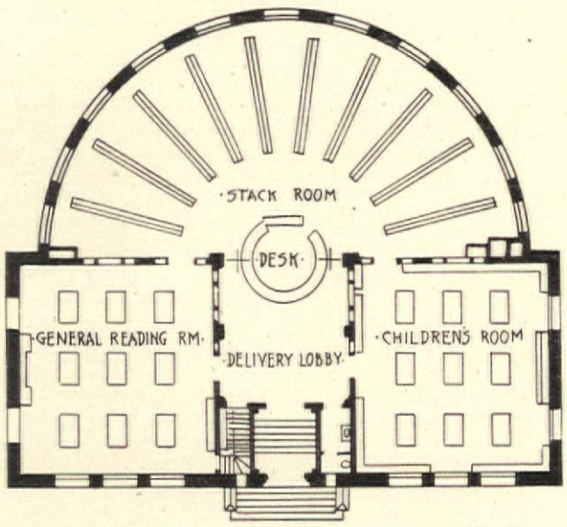
THE system of branch libraries and stations is remarkably organized in many of the large towns. At present few towns have started with a series of new buildings. Old buildings generally have been converted. such as schools, churches, private residences and shops. The branch library is therefore likely to develop very greatly in the near future. Those at Pittsburgh, Pa., which are in connection with the Carnegie Public Library there, are excellent, but they are only designed for isolated sites, and therefore represent only one type. It will be most interesting to watch the result of the work of the advisory board of architects appointed to design the 65 new branch libraries of New York. Quite a different type of plan will have to be adopted from those of Pittsburgh. The sites will be in ordinary street-blocks, between houses generally, with light from front and back only.

Some branches have already been erected in New York. The Bloomingdale branch, on a site with a frontage of 43 feet to the street and a depth of 60 feet, is a recent one, and will be described hereafter. Generally, for these branch libraries there is no need to provide more shelving accommodation than for from 15,000 to 25,000 volumes. Important books are easily obtained from the central library, and an automobile service delivers in a very short time what is asked for by telephone.

BRANCH LIBRARIES, PITTSBURGH, PA.

Up to the present time the planning of the branch library has been studied perhaps in Pittsburgh, in connection with the Carnegie Library there, more successfully than in any other town in America. There are 5 branches already erected of the 7 given by Mr. Carnegie, each on an isolated site, so differing in this respect from the branch library one would expect in a large town, where often the site is cooped between houses, with capabilities of lighting only from the front and back.

The first built was the Lawrenceville Branch, opened May 10, 1898. Its cost was about £8 000. In the preparation of the plans



First Floor: Lawrenceville Branch, Carnegie Library of Pittsburgh, Pa. Messrs. Alden & Harlow, Architects.

for this building the problem was to provide for a stack-room with a capacity of 20,000 volumes, a delivery-desk, a general reading-room and a children's room on one floor, and that every part of this floor should be visible from the delivery-desk, allowing complete supervision of the whole, so that free access to the shelves could be given to the public.

The plan will show how these requirements have been met. The general reading-room and the children's room, each 31′ x 33′ and 18 feet high, are placed on either side of the delivery-lobby, 21′ x 22′, which occupies the centre of the building. The circular delivery-desk is 14 feet clear diameter, and separates the delivery-lobby from the stack-room. The card-catalogue case is in the rear of it and faces the stack-room. The outer wall of the stack-room is semicircular, and its centre corresponds with the centre of the delivery-desk. Its radius is 37 feet 9 inches, and the 10 book-stacks, 18 feet long, radiate from the centre. From the delivery-desk, therefore, the assistants in charge command a view of its entire floor.

The 10 stacks in the stack-room have a capacity of about 25,000 volumes, which may be doubled by superimposing a second floor, sufficient light having been provided.

This branch being worked on the free-access plan, the doors C and D on either side of the delivery-lobby are unnecessary, and the entrance to the stack-room is through the registering-turnstile F, which works in only one direction, and thence to the reading-rooms through the doors A and B. The exit from all parts is through the turnstile E, which also works in only one direction. By making it necessary for every one to pass out by the delivery-desk through this turnstile, the temptation to carry a book away without having it charged is reduced to a minimum, especially since no one can feel sure that he has escaped observation at any time during his visit.

The basement contains a newspaper-room 21′ 6″ x 26′, a work-room 17′ x 17′, a boiler-room 13′ x 33′, men's lavatory, and an auditorium under the stack-room to seat 500. This has a separate entrance at the side from the street, or can be entered from the delivery-lobby by the staircase to the left of the vestibule, which descends into a *foyer*, 16′ x 25′, with entrances to the auditorium either side of the platform.

The general reading-room is fitted with 9 tables, each 3′ x 5′, with chairs to seat about 50 readers. In this room are the current periodicals in a rack, and a small collection of reference-books.

The children's room also contains 9 tables, 3′ x 5′, graduated in height to the various sizes of children. The chairs are also of various heights and sizes. Sixty children may comfortably be seated in this room at one time. All the wall-space to a height of about 5 feet is occupied by shelves holding 4,000 volumes, and the whole of the books of the children's library are kept in, and issued from, this room.

The next branch opened was the West-end Branch, January 31, 1899. This is a much smaller library than the Lawrenceville, and is without the semicircular stack-room. It also consists of 2 floors. In the basement are the workrooms and auditorium as before. The main floor is simply one large room. The central desk is placed in a similar position to that at Lawrenceville, with turnstiles either side, and the delivery-lobby is separated from the children's room and the general reading-room by railings of the same height as the turnstiles. The walls are shelved round the entire room. At the back of the delivery-desk is a small room, 16′ x 14′, projecting out from the main building. It is used as a small reference-room.

Both reading-rooms are smaller than those at Lawrenceville, being 30′ x 28′ 4″ each, and about 18 feet in height, fitted with 3 long tables, each 16′ 6″ x 30′. There are 16 chairs to each table in the general reading-room, and 18 in the children's. Its cost was nearly £4,000.

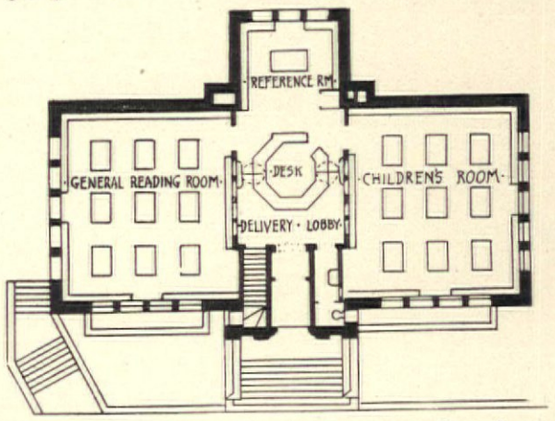
The branch at Wylie Avenue was opened in June, 1899, and practically follows the lines of the Lawrenceville, with its radiating stacks, but owing to the increased size of the reading-rooms to 37′ 6″ x 33′, giving another row of 3 tables, the stack-room is wider and not so deep. Its radius is 42 feet to about the centre of the delivery-lobby, not the delivery-desk as before, but the stacks radiate from the centre of the delivery-desk.

The Mount Washington Branch is modelled on the plan of the West-end Branch, except that glass-partitions separate the general reading-room and the children's room from the delivery-lobby. By this means a geater degree of quiet is ensured. The recess for reference-books in the rear of the delivery-desk is 14′ 6″ x 16″, and has a capacity of shelving 2,000 volumes. The other books are shelved in the 2 reading-rooms.

The turnstiles have been improved in several details, the entrance turnstile, marked F on the plan, having a frictional attachment which ensures a more accurate registration of the number of visitors. The exit turnstile, marked E, is fitted with a locking attachment, which is released by pressing a pedal located just where the charging-assistant stands within the delivery-desk.

The delivery-desk is octagonal instead of circular in form, and works more satisfactorily. On the inside it is fitted at the front with shelves for returned books, and with drawers for the shelf-list, which is kept on cards, and at the other side with drawers for borrowers' applications and cards. The case of drawers containing the card-catalogue is in the rear of the desk and faces outwards, so that it is readily accessible to borrowers.

The size of the general reading-room is 27′ 4″ x 30′, with 8 tables, seating 64 persons, 56 inches long, 39 inches wide, and 30 inches high.



First Floor: Carnegie Library of Pittsburgh, Pa., Mount Washington Branch. Messrs. Alden & Harlow, Architects.

Near the entrance to the room is an attendant's desk of the same size as the tables. The room has a shelving capacity of 5,200 volumes, the bookcases being 7 shelves high, except under the glass partition.

[1] A paper by Sidney K. Greenslade [*A.*], Pugin student, Grissell Medallist, Godwin Bursar, read before the Royal Institute of British Architects, Monday, March 17, 1902, and printed in the *Journal* of the Society. Continued from No. 1391, page 61.

In the children's room, of exactly similar size, the shelving is carried to the same height, the upper portion having a corticine-panel framed in oak. These panels altogether form a bulletin-frieze extending around the room, and make an excellent background for small framed pictures hung within easy reach of the children's eyes. The shelving capacity of the room is for 3,800 volumes. The tables (8) are of the same superficial area as those in the general reading-room, but are of 3 heights, 28 inches, 26 inches, and 22 inches, with chairs to correspond, 17 inches, 16 inches, and 14 inches high respectively. The room contains also an attendant's desk, similar to the general reading-room. Between the children's room and the vestibule is placed the women's toilet-room, the men's being in the basement. The children's room is fitted with a small cabinet wash-basin, compact in form, which folds against the wall behind closed doors when not in use. In the basement are placed the auditorium, boiler-room, store-room, workrooms, and men's toilet, etc.

The Hazelwood Branch was the last to be completed. Practically very little variation has been made. The seating capacity of the reading-room is one-third greater, the dimensions being 26′ 8″ x 38′ 6″, each having 12 tables; and the small reference-room is contained within the main lines of the building, just behind the delivery-counter. It is only temporary, until the stack-room is built over the existing semicircular auditorium. The fittings of the delivery-desk and shelving, etc., are exactly similar to the others.

Living quarters for the janitor are provided in a half-story above the main floor.

It is interesting to note the gradual development of these plans. The growth of what may be called the "turnstile control," resulting in the abandonment of the entrances to the reading-rooms from the delivery-hall, as adopted on the first plan, is important.

The apparent unfitness of the low railing separating the reading-rooms from the delivery-hall, as adopted in the West-end Branch, and substituted afterwards by screens in the later plans, is also worthy of note. Although the radial-stack plan is costly to build, yet the advantages where a "free access" policy is adopted are very great. The architects for all these libraries were Messrs. Alden & Harlow, of Pittsburgh.

NEW YORK CITY BRANCH LIBRARIES.

In a very few years the city of New York will have a most complete scheme of branch libraries in connection with its magnificent central one. Mr. Andrew Carnegie has given £1,000,000 to build 65 branches, and the Board of Library Trustees have just appointed 3 firms as an advisory board of architects to take the entire charge of the designing and supervising of these buildings, the firms so appointed being Messrs. McKim, Mead & White, Messrs. Carrère & Hastings, and Messrs. Babb, Cook & Willard. There will be a certain number of libraries built each year, and the above firms will confer and collaborate in the work. The result should be eminently satisfactory.

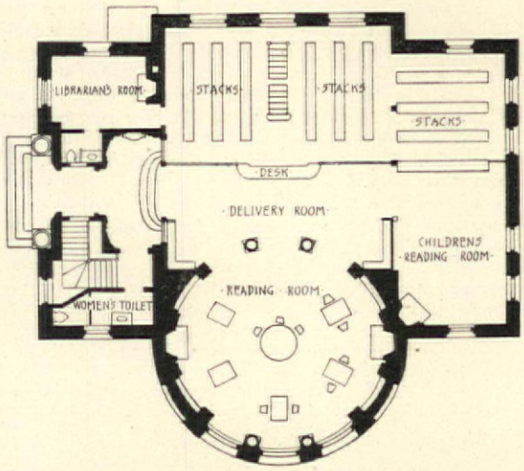
Among the branch libraries already built in New York, perhaps the Bloomingdale Branch will best serve as an illustration of the arrangements adopted. It is built on a site with a frontage of 43 feet and depth of about 60 feet. Lighting is only obtainable from the front and an area at the back. It consists of a basement and 3 floors above, and the whole of the main-floor area is open. The front portion is occupied by the delivery-space, about 23′ x 9′. Beyond, placed centrally, is the delivery-desk, enclosing a working-space for attendants 14′ x 7′. The rear of the room is divided by a bookcase, 7 feet high, into two, 2 tables for 6 readers being placed on either side. A portion by the side of the delivery-desk, to the front, is reserved for children. Bookshelves are placed around the walls to a height of 7 feet. Gates and low railings separate the delivery-space from the other portion of the room. The stairs to the upper floors are in the far right-hand corner, and are lighted from the area. The whole of the first floor is also open, and is used as the general reading-room. Book-lifts from the delivery-desk below are placed in the centre of the room. It is fitted with 12 tables for 6 readers each.

The upper floor is allotted to the janitor and for purposes of the travelling-library.

SMALL LIBRARIES.

In the State of Massachusetts the requirements of the small library have been particularly well studied. Hardly a village or hamlet is without one. Many of those around Boston are extremely successful. It was here that Mr. H. H. Richardson, about 1880, erected several that are well known, such as the Ames Library, at Easton, and those at Woburn and Quincy. The great feature of the plan he generally adopted is the alcoved main reading room, and in these alcoves all the books were shelved. The stack-room, as understood now, did not exist. This method has not been found wholly successful from the readers' point-of-view, although architecturally the general effect of the alcoves is good. Many of the recently-erected libraries have very simple and compact plans. Those at Wayland, Plymouth and Weston have been selected to illustrate this, and also because the buildings are quiet and well suited to their surroundings. Often the small memorial library fails because it is so monumental in character. The plan often adopted for this type consists of 4 rooms, the 2 reading-rooms either side of the domed central hall, and the stack-room in the rear. They are often just miniatures of large town libraries, and look out of place.

The little library at Wayland, Mass., is admirably planned. Practically the whole is one room, easily controlled from the attendant's desk, yet ingeniously contrived so that the reader when in the reading-room is not disturbed by the borrowers at the delivery-counter. From the inner hall there are 3 steps up into the delivery-room, which averages 12 feet wide by 33 feet long, with the delivery-counter,

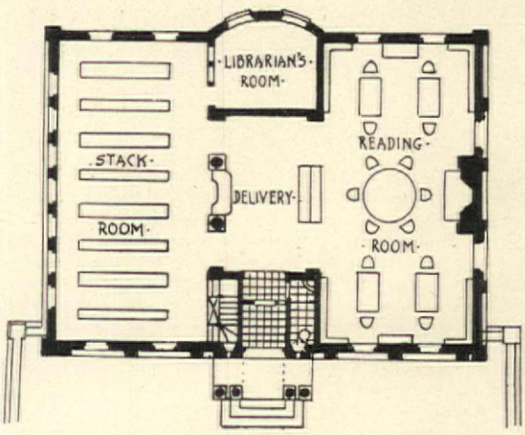


First Floor: Public Library, Wayland, Mass. Messrs. Cabot, Everett & Mead, Architects.

stack-room, and librarian's room to the left. To the right is the reading-room. Either side of the counter the stack is separated from the delivery-space by a low railing with gates in it. The reading-room is circular in plan, with a diameter of 32 feet. One-quarter of the circle is open to the delivery-room, divided into 3 openings of 6 feet each by 2 columns. It is fitted with 5 tables, 2′ 8″ x 4′, seating 2 readers each, and a circular table in the centre of the room, 6 feet 6 inches diameter, seating 6 readers. There are 3 large sash-windows, corresponding to the 3 openings from the delivery-room and opposite to them; and between are 2 open fireplaces, with bookshelves either side. The children's reading-room is beyond the delivery-room, and is 24′ x 17′, fitted with 2 tables seating 4 each. A stack, in which their books are shelved, to hold about 1,000 volumes, separates the room from a small room, 15′ x 15′, behind, practically a portion of the book-stack, which could be conveniently used as a small reference-room.

The stack-room is fitted with 6 rows of stacks, 3 on each side of centre, each row divided into 2 lengths of 6 feet each, with gangway between. Just at present they will take 10,000 volumes, but on the second floor further stack accommodation can be arranged for more than twice this number. The approach to this floor is from the staircase at the back of the delivery-counter only, so the storage accommodation for the size of the library is great. The architects were Messrs. Cabot, Everett & Mead, of Boston.

In the Russell Library, Plymouth, Mass., by the same architects, the scheme adopted is a smaller one, but similar in arrangement; generally the rooms are more open in plan, and there is no division between the stack and delivery room. A seat with bookshelves at the back separates the reading-room from the delivery-space. The stack-room to the left is 20′ 6″ x 40′, having 8 rows of stacks 12 feet long, with a total capacity of 13,440. Provision is made for a second floor; it is to be of glass, with a gallery towards the delivery-space; it is reached by a staircase in the front corner of the stack. The space



Russell Library, Plymouth, Mass. Messrs. Cabot, Everett & Mead, Architects.

over the librarian's room is occupied by a private study-room, the only room on the second floor.

The librarian's room on the first floor opens directly off the stack and is placed beyond the delivery-space. The reading-room to the right is 20′ 5″ x 40′ and 16 feet in height; it is well lighted on the three sides and shelved all around for books. It is fitted with 5 tables.

Unlike the majority of the small libraries, that at Weston is ⌟-shaped in plan. Directly opposite the long arm on the short side the entrance is placed, and directly beyond is the delivery-hall, 15 feet square. To the left, through an opening 14 feet wide, divided into three by 2 oak columns, is the reading-room. It is 44 feet long and 24 feet 6 inches wide, and very well lighted on three sides. It is fitted with 2 tables, each 13′ x 3′ 6″, and a circular one at the end of the room, seating altogether 22 readers. Between the columns on the right of the hall is a settle which divides off the children's small room, 11′ 6″ x 15′ 6″, also provided with a circular table seating 5. Both these rooms are fitted with wall-shelving between the windows. The book-room occupies the long arm of the ⌟. It is about 56 feet long by 30 feet wide. The opening between it and the delivery-hall is 14 feet wide, and is divided into three by 2 columns, like the other room. The delivery-counter is placed in the centre; a desk occupies the left opening, for the use of the librarian, and a gate is placed in the right one. The first 10 feet of it on the left is fitted for the librarian, and commands a view of all the rooms from her desk; beyond, it is divided into 5 well-lighted bays of 10 feet centres. There is a central 6-foot-wide gangway and small ones 3 feet wide at the walls. The stacks, which are of wood, 9 feet long and 8 feet high, have a capacity for shelving 11,340 volumes. This does not include the wall-shelving in each bay below the windows. Between these stacks, near the wall, are placed small fixed tables, each 18″ x 2′ 6″, supported by central cast-iron standards screwed to the floor, and fitted with a fixed stool at the wall end. A lift and staircase connect with the floor below the book-room, which is of the same area. This is an extremely convenient and well-arranged little library. The architect was Mr. Jenney, of Boston.

In conclusion I should like to express my great thanks and indebtedness to all the librarians and architects who so readily assisted me in my work, and particularly to those who kindly gave me plans of their libraries for the Institute. These courtesies, so generously shown, made my visit to America as Godwin Bursar a most pleasant one.

THE ROYAL PALACES OF LONDON.[1]

THE royal palaces of London have a special interest this year, when the English monarchy and its historic associations are vividly recalled to men's minds by the coronation of King Edward VII. Of these palaces only one, and that the least interesting — Buckingham Palace — is the residence of the King. St. James's still remains the official court and the scene of levees and investitures. But the glories of Kensington and Whitehall are wholly of the past.

Little or nothing is left of Whitehall, if we except the magnificent banqueting-hall. Yet the palace of Whitehall was for centuries the chief London residence of our monarchs, and no review of the royal palaces of London would be complete which did not take it into account. The original building of Whitehall was erected in the reign of Henry III by Hugo de Burgh, Earl of Kent and Chief Justiciary of England. At his death it passed either by will or sale into the hands of some Preaching or Black Friars, and they sold it in 1248 to Walter de Grey, Archbishop of York. From that time to the fall of Cardinal Wolsey, nearly three centuries later, it served as the London residence of the northern primates, and was called York House. As an archiepiscopal palace, York House was for long the centre of much ecclesiastical pomp and state. But it was Wolsey who raised it to its zenith; he rebuilt a great part of the palace, and added a hall and chapel. At York House this prince of the Church entertained with sumptuous magnificence; the splendors of his equipage and liveries, the costliness of his entertainments, and the profusion and extravagance of his household were never before equalled by any English subject, peer or prelate. But Wolsey's day at York House, though brilliant, was brief. Anne Boleyn was prejudiced against him, and King Henry VIII attributed to him the failure of the negotiations for the divorce of Catherine of Aragon; perhaps, too, the pomp and display affected by the Cardinal aroused the King's jealousy. Wolsey was ignominiously turned out of York House; the palace was seized by the King, and henceforth called Whitehall. Some authorities say that the unfortunate Cardinal handed the palace over to his rapacious master as a peace-offering in vain, others that the King took it without ceremony. However that may be, it is certain that Henry VIII got Whitehall for nothing, and could therefore afford to enlarge and beautify it. This he did in many ways, notably by obtaining land from the Abbot of Westminster, and enclosing it with a wall as a park "for his Grace's singular pleasure, comfort, and commodity," as Strype has it, "to the great credit of the realm." The King also added to the palace a spacious room for entertainments, a finer chapel, galleries, a cockpit, and a tennis-court. When all was completed Henry VIII came to Whitehall with his Court, and the palace henceforth became the principal London residence of our English monarchs until it was destroyed by fire more than a century later.

The succeeding Tudor sovereigns did little or nothing for Whitehall. James I on his accession found the palace sadly out of repair, and resolved to rebuild it on a regal scale. He consulted Inigo Jones, who prepared elaborate plans, far beyond his royal master's means or needs. They were only in part carried out, but the superb banqueting-hall remains to this day a witness of the magnificence of the architect's designs. For the rest, it has been well said that "the Whitehall of Inigo Jones is an unrealized dream."

Charles I at one time thought of carrying on the work begun by his father, and employed Rubens to paint the ceiling of the banqueting-hall, and commissioned Vandyck to paint the walls, but political troubles came all too soon, and Vandyck's commission was never executed.

After the Restoration, Charles II commanded Sir Christopher Wren to draw up plans for the improvement of Whitehall, but through lack of money nothing was done, and until the end Whitehall remained much as Inigo Jones had left it. Even so it was a truly regal palace, chiefly in the style of Tudor architecture, a large rambling building, or rather group of buildings, extending far along the river. . . .

After the death of Mary, William III came but rarely to Whitehall, possibly because his sister-in-law Anne, whom he hated, had lodgings there at one time. Four years before his death, in 1698, Whitehall was burned to the ground. As a royal residence it ceased to exist, and only the magnificent banqueting-hall remained to bear witness of what was once the stately Palace of Whitehall. After the accession of George I this hall was converted into a Chapel Royal, and it so remained until 1890, when it was dismantled as a place of worship. Many notable services were held in the Chapel Royal, Whitehall, not the least interesting being the thanksgiving service attended by their present Majesties and all their children the day after their silver wedding (March 11, 1888), when the eloquent Dr. Magee, Archbishop of York, preached.

Shortly after this event the hall was closed as a Chapel Royal. It was "lent" by Queen Victoria to the Royal United Service Institution, and has since been fitted up by that body for the exhibition of trophies connected with the history of the army and navy. . . .

The burning of Whitehall led to the recognition of St. James's as a royal palace. For though St. James's was first acquired by Henry VIII, it was not until the reign of William III that it became the accredited seat of royalty. The phrases, "The Court of St. James's," "The Palace of St. James's," date from the Revolution era — before then it had been "The Court of Whitehall."

The Hospital of St. James's, founded for the reception of "fourteen sisters, maidens, that were leprous, living chastely and honestly in divine service," was acquired by Henry VIII in the year 1532, by comparatively honest means, for though he turned the sisters out of doors he granted them pensions. The hospital was razed to the ground, and St. James's Manor-house was erected in its place, under the direction of Cromwell, Earl of Essex. Holbein is said to have furnished the plan, but this may be doubted. Henry VIII entered into occupation of his "goodly mansion of St. James's" at a time when his passion for Anne Boleyn was at its height, and carved on the chimney-piece of the presence-chamber may still be seen the Tudor badges and the initials H. A. intertwined — the cipher of the monarch lover and his swanlike bride. Anne Boleyn must have spent some of the happiest hours of her brief reign at St. James's, and have witnessed there many a stately masque. The King, perchance, associated St. James's with his wayward fancy for Anne Boleyn, for he seldom went thither after her tragic death, but repaired to his more commodious palace of Whitehall. Mary, his daughter, passed much of her time at St. James's. From its gates at her accession she rode in state to Whitehall with the Princess Elizabeth at her side. The Tudor sisters rode on white palfreys, gaily caparisoned, and followed by a brave show of ladies and knights. In St. James's, too, a few years later, Mary dragged out the last days of her inglorious reign, weeping over the loss of Calais, and sighing for Philip, her husband, who came not.

After Mary's death the course of events flowed away from St. James's. Elizabeth cared nothing for the palace, but she sometimes held receptions in the state apartments. James I went thither but little, and though he affected to be pleased that it bore his name, the magnificence of Whitehall appealed much more to him. So he made over the Manor-house of St. James's to his son Henry, Prince of Wales, who occupied it until his premature death. Charles I had a liking for St. James's, and most of his children were born there. So, too, had Queen Henrietta Maria, who lodged a colony of priests and friars in the Friary Court, to the great indignation of the Puritans. . . .

But it was not until the accession of George I that St. James's became actually the residence of the sovereign, a place to live in as well as the scene of levees and drawing-rooms. What Whitehall was to the Stuarts, St. James's became to the first two Georges. . . .

St. James's as a place of residence did not long enjoy the royal favor after the accession of George III. But it was to St. James's that Princess Charlotte of Mecklenburg-Strelitz came as the bride of the young King. When she first saw the palace she turned pale and trembled. The Duchess of Hamiliton, who had been sent to attend her, reassured her with a smile. "My dear Duchess," said the young Princess tartly, "you may laugh, for you have been married twice, but it is no joke to me." When the coach stopped, and the King came forth to meet her, she trembled and would have knelt at his feet, but he gallantly prevented this and embraced her. It is said that for a moment — only for a moment — he started with dismay, her portraits had made her so much fairer than she proved to be. But it was too late to draw back, and the "plain, awkward

[1] Extracts from a paper in the *Edinburgh Review* for July, 1902

German girl" became "good Queen Charlotte," of penurious and shrewish memory.

The eldest son of this union, George IV, was born at St. James's, and here for a short time King George and Queen Charlotte resided when in London, and held levees and drawing-rooms. But in 1763 they moved their household to Buckingham House. From that date St. James's Palace has never been the residence of the reigning sovereign, and for a time it fell into disfavor. . . .

Kensington Palace will be chiefly known to future generations as the birthplace and early home of Queen Victoria. The original mansion, of which, it is probable, some portion still stands, was the residence of Lord Chancellor Finch, afterwards Earl of Nottingham, and bore the name of Nottingham House. The estate included some park-land, now known as Kensington Gardens. King William III bought it from the second Lord Nottingham, as Northouck writes, "for its convenience and healthy situation, and for the King to reside in during the sittings of Parliament." Evelyn, in his "*Memoirs*," under date February 25, 1690–91, writes: "I went to Kensington, which King William has bought from Lord Nottingham, and altered. It is yet a patched-up building, but with the gardens, however, a very neat villa." The palace was considerably enlarged by William III and Queen Mary, from designs by Sir Christopher Wren, and prim gardens with straight paths and formal flower-beds were laid out in the approved Dutch fashion. William and Mary were very fond of Kensington, and spent large sums in altering and improving their newly acquired estate. Before the work was completed, Queen Mary died at Kensington of smallpox, December 28, 1694. When the nature of her illness was communicated to her she realized that there was no hope, and locked herself in her closet, where she spent the night in sorting and burning her private papers. A few days later she died. . . .

Anne was even more attached than her predecessors to Kensington, and though she did little to improve the palace, she devoted much time and thought to beautifying and enlarging the gardens, and spent hours pottering among her plants and flowers. The beautiful greenhouse or orangery was built by Sir Christopher Wren at her command. If there be such a thing as a "Queen Anne" style of architecture, this building may be regarded as its highest expression. It shows Sir Christopher Wren at his best. Queen Anne used to come to the orangery sometimes to drink tea, and here she often sat squabbling with the haughty Sarah, Duchess of Marlborough, or gossiping with the cunning Abigail Hill, Lady Masham. Anne died at Kensington from a stroke of apoplexy, brought on by the strife and contention of her ministers, and her sudden death defeated the ill-matured plans of the Jacobites. . . .

George I was fond of Kensington, which reminded him, more than other English palaces, of his beloved Herrenhausen. Sir Christopher Wren having been turned out of his place by a base Court intrigue, William Kent, a man immeasurably his inferior, was appointed in his stead, and to him George I gave orders for the erection of a new and additional suite of state-rooms, including the famous cube or cupola room, a gorgeous chamber of the pseudo-Classical style, with painted and gilded walls, and a gaudy domed ceiling of blue and gold. . . .

On the accession of George II and Queen Caroline Kensington became one of the favorite residences of the Court. Queen Caroline's drawing-room, built and decorated by Kent, was the scene of many an interview between her and Walpole. Here together they concocted schemes for the management of the King, and here, too, Caroline would often give audience to malcontent nobles, like Lord Stair, and endeavor to win them over to the side of the Government. Caroline was devoted to gardening, and with the assistance of Kent, who was a better landscape-gardener than an architect, she planned many alterations in Kensington Gardens. It was she who made the Round Pond, turned a string of smaller ponds into the Serpentine, and laid out the Broad Walk and many of the smaller avenues. Under Queen Caroline the Kensington promenades were revived, and became more frequented than ever. The King and the Queen were very fond of walking, and, accompanied by the princesses and attended by a numerous body of courtiers, they would give many informal audiences in Kensington Gardens in the course of their morning walk. George II died at Kensington Palace twenty-three years after the death of his Queen. With him the glory of Kensington as a royal residence to a great extent departed. . . .

The state-rooms at Kensington Palace have been carefully restored, and by command of her late Majesty are now open to the public. Here may be seen Queen Mary's privy chamber, Queen Anne's private dining-room, the magnificent king's gallery, the cupola-room, Queen Victoria's nursery, and many other apartments. But the most interesting of all, the room in which Queen Victoria was born, and the room in which she held her first Council, are not shown.

Buckingham Palace has been left to the last, for it possesses few historic memories and has the reputation of being the ugliest royal palace in Europe. The reputation is not altogether deserved, as those who have witnessed the gloomy and forbidding barracks which do duty as royal palaces in some of the capital cities of Europe can testify. From the garden-front, at least, Buckingham Palace has a certain stateliness which is not unworthy of the principal London residence of the King. In the far-away days when the Court disported itself at Whitehall the site of Buckingham Palace was known as the Mulberry Garden. This garden was a fashionable resort during the reigns of Charles I and of Charles II, and was the scene of many gay comedies. There was a house adjoining the Mulberry Garden known as Goring House, which was later purchased by Lord Arlington, and rebuilt on a larger scale, and styled Arlington House. This was demolished in 1703, and upon its site John Sheffield, the magnificent Duke of Buckingham, built a mansion and named it Buckingham House, situated, as he says, "in a little wilderness full of blackbirds and nightingales." . . .

George III and Queen Charlotte were looking about for a mansion which would serve them as a London residence in the place of St. James's Palace, which they both disliked. Buckingham House was therefore purchased by the King and settled upon Queen Charlotte as her special property and called Queen's House. The royal pair entered in possession of their new London home, which was then a commodious red brick mansion surrounded with beautiful gardens. To make the grounds even larger a portion of the Green Park was added. Here "Farmer George" and his Queen lived the quiet domestic life they loved so well, all state functions taking place at St. James's Palace; but later, when the grand saloon at Buckingham House was fitted-up as a throne-room, Queen Charlotte held her smaller drawing-rooms there. . . .

The King and Queen were at Queen's House the night when the Gordon Riots were raging, and the troops which guarded the palace had no straw to lie upon. "My lads," said the King, "my crown could not purchase straw for you to-night, but depend upon it I have given orders that a sufficiency shall be sent here by to-morrow noon. As a substitute for the straw my servants will instantly serve you with a good allowance of wine and spirits to make your situation as comfortable as possible, and I shall myself keep you company till to-morrow morning." He kept his word, and sat up all night with the officers in the Queen's Riding House, sending messengers every now and again over to St. James's Palace to report on the proceedings of the rioters who were trying to force an entrance there.

When George IV came to the throne, the "Queen's House" was in a very dilapidated condition, and the King determined to rebuild it. He had not long finished his grotesque pleasure-house, the Pavilion at Brighton, and as there was a little difficulty about getting the necessary supplies from Parliament to build a new palace in London, he cunningly asked for a grant for "the enlargement and repair of the Queen's House and got it." Nash, the architect, had the King's command to keep up the fiction of repair, but very soon the Queen's House was transformed into the King's Palace of Pimlico. George IV, with all his faults, had a sense of the magnificent, and he dreamed of a palace which should rival those of ancient Rome. The palace grew and grew, and a notable feature of the "repairs" was the magnificent marble arch copied from that of Constantine at Rome, upon which an equestrian statue of the King was to stand. This statue was never placed there, and, shortly after Queen Victoria's accession, the Marble Arch was banished to the Oxford Street entrance of Hyde Park. The King's repairs and additions cost half a million of money, and by the time they were finished every trace of the original structure of Buckingham House was lost. The work was not ended when George IV died, and his successor, William IV, swore that the palace was a monstrosity, and declared that nothing would induce him to live in it. So it remained uninhabited and deserted, surrounded by a wilderness of sandy gravel, until Queen Victoria came to the throne.

The young Queen declared that she liked neither Kensington nor St. James's, but would in the future make the King's Palace at Pimlico her London residence. The palace was soon finished and upholstered, and the Queen decided that she would call it in future Buckingham Palace. In July, 1837, she quitted Kensington and drove through cheering crowds to her new home, passing under the Marble Arch, whereon the Royal Standard floated for the first time. In the early years of Queen Victoria's reign Buckingham Palace was considerably altered and improved. The magnificent ball-room was built and the gardens were beautified under the direction of the Prince Consort. Though, after her husband's death, she resided in London but little, Buckingham Palace was always the centre of Queen Victoria's life in the metropolis during her long reign of sixty-three years. She drove from it to her coronation and her wedding, and here many of her children were born. From its windows she watched the funeral of the great Duke of Wellington passing to St. Paul's, and from the balcony she waved farewell to her Guards as they set forth to the Crimea. Through the great bronze gates of Buckingham Palace Queen Victoria passed to the thanksgiving of her Jubilee in Westminster in 1887, and ten years later they swung open again when the aged Queen went forth to celebrate with her people her Diamond Jubilee.

PROFESSIONAL OBLIGATIONS.

THERE are few men in the profession who are capable of managing their clients, though they may be quite competent in their own business and in other ways. Yet this power of management is very essential to a successful conduct of business. The cantankerous or litigious client is extremely difficult to manage, for he seems always thinking that he is being worsted. This belief haunts him night and morning, and he is always trying to find out a mistake or pick a quarrel with architect or builder. And here it is

where a knowledge of men and business tact are so essential to the profession. They cannot learn it from books: it can be only mastered by experience. The cantankerous client is very sensitive; he resents anything which seems to him to be a slight or an inattention, and, therefore, the best way is to meet him half-way, to humor him in small things, to be tactful, to consult him now and then, his likes and dislikes, and so to win his friendship and confidence as far as possible without giving oneself away. But the tactful behavior is not everybody's *forte*. In nine cases out of ten the architect puts his back up, goes the wrong way to conciliate, gives orders without consulting, and is in the habit of doing the wrong thing or at the wrong time. The management of a client of this kind can only be got from a long personal acquaintance with him, his tastes and whims, and it is this study of the personality of the client that is so often lost sight of by the profession. . . .

There are several matters of contract with which the architect is often unfamiliar. His relation to the contract is of the first importance. As an agent of the employer he is answerable for acts of negligence, and in this capacity he is liable for six years, and payment does not relieve him from his liability; but he is not liable to the contractor unless for fraud or collusion. And what does this agency or liability imply? His client expects of him a knowledge of the law in regard to buildings; he ought to know the general law of contract, the law of easements — as light and air, rights of property, party-walls, etc.; he should be practically acquainted with the Building Act, local Acts, by-laws and regulations, sanitary and otherwise. These constitute a considerable knowledge of municipal and statutory provisions; he cannot delegate his duties to another; he is also liable to his client for the faults and errors of his assistants. But the architect is not so much a general agent of the employer as a special agent, and this limitation is important. Thus he is appointed to see that his plans are properly carried out, and this involves good foundations, sound walls and floors, drainage and other structural matters, responsibility for defects of design, and all injuries sustained by collapse, or errors in estimating cost. A most important duty often neglected is that relating to the rights of building and adjoining owners on party-walls, and a thorough knowledge of the schedule and provisions of the Building Act is necessary. Many an architect has come to trouble owing to his neglect of a knowledge of light and air. Plans have been prepared and building operations commenced, when a complaint is made that the new building will obstruct the light that comes to a window which has had an uninterrupted enjoyment of it for the prescribed period. It is then found that the owner of dominant tenement has a right, and that the building must be stopped, or alterations made to avoid the consequences. And his knowledge of the law must be up to date. For example, recent decisions on the question of the amount of lateral light that can be acquired by long enjoyment have to be studied. . . .

There is much misunderstanding prevalent in the profession about the ownership of drawings for buildings not proceeded with. The law has decided that the employer can claim the drawings if no agreement to the contrary has been made; if the building is carried out, the architect has been ordered to deliver the drawings, though on insufficient grounds. But in either case the architect can make his own terms.

A great deal often turns on the real meaning attached to the usual contract-clause "In case of any dispute arising between the parties, the architect's decision in the matter shall be final and binding." He can decide solely by his skill or judgment, without hearing the parties; he is acting in the position of a quasi-arbitrator, who gives his decision without having to inquire into the matter of dispute between the parties; he is in the position of a valuer or a "dispute preventer." The architect in this case acts upon his own judgment on the facts. But when he is appointed by two or more parties to determine or value a matter after a dispute has taken place, and to settle that dispute, and he is expected to hear evidence, then he is acting in a judicial position as arbitrator. Neither employer nor contractor can dismiss an architect who is acting as a quasi-arbitrator — an important difference between the architect who acts merely as an agent and one who acts as dispute-preventer or quasi-arbitrator. It is well for the architect to keep in mind these two functions of his work — that of an agent and that of a quasi-arbitrator — being responsible to his clients in certain duties, and holding also a position of dispute-preventer between the parties to the contract. By having a clear conception of what these functions imply, he may be saved many mistakes and misgivings, while he will be able to maintain a firmer attitude towards his employers and the contractor. As arbitrator or quasi-arbitrator he is not the agent of either party, for he is acting for both; hence, he is not responsible to either of them for his acts, as, for instance, in giving certificates, ordering extras, and making valuations, which are binding alike on both. This independent position ought to save him from much annoyance and threats of dismissal, or to appoint another architect to decide points under the contract. It could only be by the joint action of both parties to the contract that another architect could be appointed. An architect has an implied authority to do many things, such as to instruct a quantity-surveyor to prepare quantities, to order certain things, to give final certificates — all of which things he could not do if he were not a special agent, or if, for example, he had been engaged only to supply a set of drawings for a builder to carry out independently, in which case he is not an agent, but a draughtsman. — *Building News.*

THE NEW ITALIAN LAW ON DEALINGS IN ART.

THE Roman correspondent of the *London Morning Post* transcribes from the *Official Gazette* the new law regulating trade in artistic and archæological objects, and recently adopted by the Italian Parliament. That the authorities are resolved to protect the artistic interests of the State in the most practical manner is shown by the following interesting passages in the correspondent's letter: —

"All artistic or archæological collections, monuments or isolated artistic objects belonging to the ecclesiastical authorities and to corporations recognized by the State cannot be sold out of the country, and can only be sold in Italy by one religious or public authority to another, or to the State, with the permission of the Government. A general catalogue of pictures, monuments and archæological objects is to be drawn up, one part of the catalogue to include the objects and collections belonging to the above-mentioned corporations and authorities, and the other to include all objects and collections belonging to private owners, provided that these collections are considered to be of high artistic value. Objects not included in the catalogue may be sold, but only with the permission of the Minister of Public Instruction. Owners of objects registered in the catalogue must immediately notify the Ministry of Public Instruction in case of sale or change of ownership. Sellers must always warn buyers when an object they are about to purchase is registered in the national catalogue. The Government will always have the right of preëmption, under equal conditions, in case of such sales, but the right must be exercised within six months of the notification that a sale is contemplated. When the right is exercised in regard to an object for which an offer has been made from abroad, the price will be fixed by deducting the export duty from the amount offered. The export duty is progressive, and amounts to 5 per cent up to the first £200 of the price, 7 per cent on the next £200, 9 per cent on the third £200, 11 per cent on the fourth £200, and so on until the maximum of 20 per cent is reached for costly objects.

"Article 8 of the law contains a provision which, if properly applied, would stop the practice of declaring the value of an object to be infinitely lower than it really is. Exporters of valuable pictures and other objects which may be worth, say, £5,000 will often declare their value to be £15 or £20, not so much in order to avoid payment of the export duty (which will, in any case, be paid by the foreign purchaser) as to avoid arousing the suspicion of the Government experts that a good picture may be going out of the country. It does not say much for Government experts that, in order to tell a valuable picture from a worthless one, they should need to see a high declaration of price, yet this is frequently the case, and during the last few years many a valuable work has easily obtained a permit for exportation because its value was declared at £12, instead of £1,200. Article 8 of the new law, however, says that the Government will have the right to buy all objects for which permission to export is requested at the price declared by their owners, less the export duty. The purchaser of a valuable picture will think twice before declaring its value to be only a few pounds, because he will know that in case of suspicion he would be bound to accept the few pounds, less 5 per cent, from the Government as the price of a picture for which he may have given £1,000. The net effect of the new law will probably be to kill the trade in authentic pictures, and to stimulate the production of those ingenious forgeries which do not figure in trade-returns as the staple article of Italian commerce, but which certainly bring more money into the country than the usual commodities for exportation."

NOTES AND CLIPPINGS

THE HERMES OF CYTHERA. — M. André, the French artist, says the Athens correspondent of the *Times*, receives 20,000 francs for restoring the great bronze Hermes that was found in the sea off Cerigo in fragments. Dr. Charles Waldstein pronounces the figure to be a work by Praxiteles or of his school, and he and other experts declare that it is undoubtedly the finest Greek bronze yet discovered. At the same time was found a marble figure of a wrestler — strikingly like a Parthenon metope now destroyed, but known through a drawing by Jacques Carrey — in workmanship of the Rhodian or Pergamene school, and Lysippan in type.

FERRO-CONCRETE. — An interesting article on "Ferro-Concrete and its Applications" appears in last month's issue of the *Engineering Times*, from the pen of Mr. L. G. Mouchel. It is some years since the idea was formed of moulding concrete with the addition of a metal skeleton, but for some time the system was employed in a timid and tentative manner. Recently, however, the French Government created a separate Department of the Ministry of Public Works to give attention to all matters relating to ferro-concrete construction, with a view to its greater development. The Hennébique system of ferro-concrete, which gained for its inventor the Grand Prix at the last Paris Exhibition, consists of a combination of Portland-cement concrete and steel, in such a manner as to form a beam in which each of these two materials would develop the maximum of its inherent properties — the concrete, of course, acting in compression, and the steel in tension. Ferro-concrete has been adopted in the foundations of heavy buildings in this country, notably in the case of the big flour-mill and grain-elevators erected at Swansea for Messrs. Weaver & Co., and a warehouse at Newcastle-on-Tyne for the Coöperative Wholesale Society. The foundations of the Swansea buildings consisted of ground made of sand and rubbish brought over as ship's ballast and tipped on the soft mud in the estuary of the Swansea River. A sill of this ferro-concrete underneath the foundations has been found to ensure perfect stability. — *Stone Trades' Journal.*

GASOLINE AUTOMOBILES. — The Boston Manufacturers Mutual Fire Insurance Co. sends out the following admonition: "We learn that in some cases members or others in charge of risks insured by this Company are making use of the gasoline automobile. However safe or otherwise these machines may be upon the road according to their kind, their care, housing and charging are subject to the special hazard of gasoline vapor. In view of the number of bad accidents in the charging-room of these machines, caution is given that the place for housing and charging gasoline automobiles should not be in any of the insured premises within the mill-yards covered by our policies. If they are brought into the mill-yard a separate building, uninsured, should be put up for housing and charging. That building should have *bottom* ventilation directed toward the outside of the yard, downhill if possible, vents at the floor-level or below, so that the heavy gasoline vapors may drain away as fast as made. We have urgent reason for giving this caution, not from any loss or damage to insured property, but from bad accidents which have occurred within the month to one of our most valued clients."

LIGHTING BY MEANS OF ALCOHOL. — Although the flame of pure alcohol is not luminous, it may be made so by carburizing the spirit with the addition of 35 to 60 per cent of coal-tar benzine; or the flame of uncarburized alcohol may raise to incandescence a mantle of the rare metals as in incandescent gas-lighting. Hence, the two main divisions into which alcohol lamps may be classed — those with free flame from carburized spirit, and those with uncarburized spirit and incandescent mantle. The lighting exhibits at the Paris Industrial Alcohol Exhibition were practically divided into three categories, viz.: — (1) Lamps (for lighting streets, stations, works, etc.) of 60 to 800 candle-power, consuming from 1 to 1.6 gramme (1 gramme is 1.30 ounce) of debased alcohol per candle-power per hour, or of 100 to 1,000 candle-power, consuming from half a gramme to 1 gramme per candle-power per hour; (2) incandescent lamps of 12 to 50-candle-power for domestic use, consuming from 1 to 3 grammes of carburized or uncarburized alcohol per candle-power per hour; and (3) lamps of 8 to 15-candle-power, consuming from 6 to 8 grammes per candle-power per hour. Outside these categories, the jury granted a silver medal to M. Laurent for his application of electricity and use of carburized air to the lighting of incandescent lamps from a distance; and a work of art was awarded to the Société La Washington, of Paris, for its collective exhibits under two of the above-named categories. This company also received a gold medal for its lamp of high power, with two or three mantles and independent reservoir for carburized or uncarburized alcohol. — *Journal of the Society of Arts.*

MICHAEL ANGELO'S "DAVID." — The referendum has hardly made its way into the world of art, and the Society for the Protection of Old Florence probably has pioneer honors in asking the art-lovers of the world to pass on a matter of local interest. The point at issue is the erection in the Piazza della Signoria of a marble copy of Michael Angelo's colossal "David." The original, now preserved in the Academy of Fine Arts, was made for this square, as all the world knows, and there it stood for more than three centuries, until it was removed in 1687 to save it from the destructive effects of the weather. Meanwhile a bronze copy was set up on the outlying terrace below San Miniato. It is now proposed to place the marble replica where the original stood, and the opinion of all art-lovers is asked upon the project. This, it will be seen, is a revision of the preference of the sculptor and his Florentine patrons, some centuries after the event. It will be curious to see whether a plebiscite of modern art-lovers will bear out the taste of the early sixteenth century. A favorable vote might only indicate respect for tradition; an unfavorable vote would show that the contemporaries of Rodin and Saint Gaudens are quite ready to set those of Michael Angelo right. Such a disposition has been shown in recent criticism of the plan for rebuilding the Venetian Campanile. — *N. Y. Evening Post.*

COLLAPSE OF A GERMAN CEMENT TRUST. — Consul Albert, at Brunswick, informs the State Department that the efforts of the German cement syndicate to control the production and to regulate the prices of cement have failed, and the syndicate has been dissolved. In the last two or three years, so many new factories have sprung up that it was impossible for the syndicate to bring them all under one management, and the competition which has ensued has been disastrous to the trust. At the same time, dissensions have arisen within the syndicate. The struggle has culminated in a conflict of extermination between the larger factories and the smaller. Prices of cement have fallen so that they are now at least 20 per cent below the cost of production of the most capably managed works. The domestic consumption and export in Germany amount to about 14,000,000 barrels, and the productive capacity of the factories is 30,000,000 barrels, or more than twice as much; consequently the factories can only work at half their capacity, and the supply of cement on hand is so great that it has to be stored. — *Exchange.*

BOGUS ANTIQUES. — The remarkable disclosure, that one of the ancient Roman statuettes in the Museum at Vienna is found to be rich in tobacco products, and to be, in fact, indisputably made from the worn-out mouthpieces of pipes and cigar-holders, will send a shock through all the cabinets (with a small c) in Europe. It is now asserted that the majority of the antique works of art of this description are the work of contemporary Greeks who appear to have made this unsavory industry theirs. As Lord Macaulay has it in a well-known Lay: —

> Such cunning they who live on high
> Have given unto the Greek.

We may even adapt another line from the same source, by the alteration of one word, to form a motto for the collector of such curiosities: —

> Leave to the Greek his amber nymphs!

— *London Daily News.*

ENGLISH STATESMEN AS GARGOYLES. — Lord Salisbury has not received the rare honor of having had his statue erected while he is still living. Such honor is usually reserved for royalty, though Calcutta boasts a statue of the Marquis of Lansdowne as a memorial of his Indian Viceroyalty. But the visitor to St. Giles, Camberwell, may see among the gargoyles Lord Salisbury with the ears and legs of a dog. Mr. Gladstone is hard by with wings growing from his shoulders, while Lord Randolph Churchill, with open mouth, in the act of speaking, keeps company with Mr. Bradlaugh (his head horned) and John Bright. The faces of Lord Beaconsfield, Mr. Gladstone, and Lord Randolph Churchill, figure on the gateway of Magdalen College, Oxford, and Chester Cathedral has a gargoyle portrait of Lord Beaconsfield. On the western porch of St. Albans Abbey Lord Grimthorpe (its restorer) figures as an angel with wings and whiskers, and Lord Roberts has been recently portrayed in a Boer War memorial window in a Bristol church. — *London Chronicle.*

PIERRE DE FRANQUEVILLE'S STATUES. — A marble "Apollo" by Pierre de Franqueville is on exhibition in Paris, where little of this old French sculptor's work is to be seen. Born at Cambrai in 1548, he was the despair of his father, who had no belief in the career of an artist. Escaping to Paris from parental tyranny in 1564, he worked his way to Italy, and became an assistant of John of Bologna, or Jean Boulogne. For the Salviati Palace in Florence he made the "Apollo" now in Paris. England contains the largest number of his works; no less than eight of his statues decorate the terrace of Windsor Castle. They symbolize Evening, Spring, Summer, Autumn and Winter. Three represent Diana, Vulcan and Bacchus, while a group of two figures shows Pan and Orpheus. "These exquisite marbles," remarks a London paper, "are the work of French hands, and the man who executed them was paid five crowns a day and his food by a Florentine prelate. It is more than three centuries since these statues were evolved from the marble block, and there are many people in France who do not know of their existence and have no knowledge of the marvellous man who wrought them." — *N. Y. Times.*

A SKELETON FOUND IN THE WHITE HOUSE. — While, a few weeks ago, the workmen engaged in repairing the White House were excavating, a massive stone vault was encountered. It proved to be apparently the foundation walls of an old house, that had evidently stood on the same spot where the White House was afterward erected. Here was found a portion of a human skeleton. — *Exchange.*

NOTES AND CLIPPINGS. 80

THE comments of the professional and other journals on the question of the reconstruction of the Venetian Campanile are extremely interesting. Undoubtedly, Mr. C. Howard Walker will prove to have been right in his opinion, that a considerable part of the lower portion of the shaft will be found still standing, and that the foundations are practically undisturbed; so that a reconstruction on the same spot seems to be justified, not only by the sentiment which wishes to see the Campanile, if restored at all, occupy the same spot on which it stood for more than a thousand years, but by considerations of economy. As to whether it should be rebuilt at all opinions differ. The Paris *Figaro* has interviewed a large number of artists on the subject, beginning with Ziem, the great painter of Venetian scenes. He, it appears, does not wish to see it reconstructed; and many other painters and sculptors agree with him. In particular, they fear that architects may be allowed to play their "antics" about the tower. Among the architects, who, naturally, look on the matter with less sentiment, and a calmer conception of the artistic relations of the Campanile, the opinion seems to be general that the long, low buildings surrounding the Piazza of St. Mark, made still lower in effect by the strong horizontal lines of their arcades, need, to give them picturesque effect, the contrast of the lofty vertical mass of the tower. Whether the Campanile should be rebuilt exactly as it stood before is, however, a question about which architects differ. The editor of the London *Builder* gives vigorous expression to the opinion, in which we cannot quite agree with him, that the "packing-box" story, as he calls it, between the arcaded loggia at the top of the shaft and the pyramidal roof, never was anything but an unstudied and ungraceful makeshift to gain extra height, and should not be repeated. It is true that this story, decorated only by a coarse inlaid panelling, was heavy and uninteresting in appearance, but it served to give to the upper part of the tower a silhouette which was not only, to our mind, pleasing in itself, but was so characteristic of Venice, that, merely as a matter of sentiment, it would be a pity to change it. We remember a considerable number of Italian bell-towers, from that at Florence to some in Rome, and while the detail and proportions of the shafts of many of them are much more beautiful than those of the Venetian Campanile, none have an outline so well suited to the picturesqueness and variety of the group of buildings surrounding the Piazza. At the same time it would be easy to preserve the outline, without reproducing the coarse ornamentation, and, notwithstanding the opinion of those who would like to have the Campanile not only rebuilt, stone by stone, and brick by brick, but painted over after completion to imitate the "patina" of age, we should not object to seeing the "packing-box" story made beautiful and interesting by sculpture or otherwise, as a memorial of the rebuilding. As to Sansovino's Loggetta, which could hardly be improved upon, it is, fortunately, quite possible to restore it exactly in its former shape, and, practically, out of its own fragments; so that there is no reason why our children should not see the Campanile substantially as we have seen it, but with added beauty and interest.

THE people of the United States might with advantage interest themselves in the South American States, which have utilized the long interval of peace that they have enjoyed to enter upon a career of internal and commercial development which promises to be a brilliant one. Several new railways have been begun, on both sides of the Andes chain, and, before long, the plains of the upper Amazon and the La Plata will undoubtedly be made readily accessible to us by railways from the Pacific Coast. As pieces of engineering, some of the new lines are of rather startling interest. The last one, which is to cross the Andes from Lima, by way of Matucana, has already been constructed to its highest level, in the Paso de Galera, where it penetrates the ridge dividing the Pacific from the Atlantic slope by means of a tunnel, two miles long, at an elevation of nearly sixteen thousand feet above the sea. It is not surprising to learn that there is a fine view from the summit of the pass, and that trains stop fifteen minutes at the station at the entrance of the tunnel, to give passengers an opportunity of enjoying it.

A FEW years ago, Colonel North, the "Nitrate King," as he was called, who had made an enormous fortune out of the Chilian deposits of nitrate of soda, undertook to build a mansion at Eltham, near London. He secured eighty-four acres of land, and built a house which is said to have cost, with the out-buildings, about a million dollars. For a time, the mansion and estate, which were known under the name of Avery Hill, formed the topic of endless illustrated articles in the professional newspapers. In the end, Colonel North quarrelled with his architect, Mr. Cutler, and their relations ended in a lawsuit, which turned out, we believe, in Mr. Cutler's favor. Not long afterwards, Colonel North died, and the property, after lying idle for some years, has at last been sold, for one hundred and twenty-five thousand dollars, to the London County Council, which will make a public park of the grounds, and will utilize the mansion in some way to be hereafter determined.

AN instructor in science at the College of the Sorbonne, in Paris, M. Fournier, has made a study of boiler explosions, a large portion of which he thinks to be due to the inefficiency of the safety-valves in common use. As he observes, a safety-valve which is held to its seat by a spiral spring, as is the case with those on small and cheap boilers, never shows at the valve, when open, a pressure so great, by many pounds to the square inch, as that which actually exists inside the boiler, for the reason that as soon as the valve opens in the slightest degree, the escape of a portion of the steam just under the valve reduces the pressure of the remainder. Supposing the safety-valve to be set to open, for example, at one hundred pounds to the square inch, while it will begin to leak steam at that pressure, it cannot be held open until the boiler pressure is far beyond that, as the pressure required to hold it open must be one hundred pounds to the square inch plus whatever is lost under the valve by the escape of a portion of the steam. Moreover, as, with a cheap valve, the force of the spiral spring increases greatly as it is compressed by opening the valve widely, while the wider opening of the valve reduces still more the local tension of the steam, it follows that to hold the valve up, so as to keep an annular opening around it equal in width to one-fourth the diameter of the valve, which is necessary to give free escape to the steam, requires a pressure inside the boiler far greater than that at which the safety-valve is set, the difference varying with the spring, the pressure and the size of the valve. In this country, the simple spring safety-valve is only used on the cheapest boilers, our engineers having long understood its defects, but M. Fournier's interesting paper will be useful, even here, as showing clearly the nature of the danger attendant upon its employment.

MR. LAURENCE HARVEY, who has just made a visit to Athens, writes to *La Construction Moderne* a letter which will interest architects, and, particularly, those American architects who have made a scientific study of the monuments on the Athenian Acropolis. Mr. Harvey, it may be remarked, belongs to the modern school of architects, in that he likes to compare the information furnished by poets and essayists in regard to architecture, with the evidence of his own senses, and, occasionally, with the conclusions which his trained intelligence suggests to him. Studying, before the ruins of the Propylæa, the rapturous description of Baedeker's *Guide*, he was surprised to read that the interior columns, of the Ionic order, were three feet two inches in diameter at the foot, and thirty-three feet seven inches high. This would make them nearly eleven diameters high, and, as a conscientious pupil of the École des Beaux-Arts, he was not prepared to admit that an antique example of the order could be so abnormally slender. Moreover, the height given by Baedeker would bring the capitals of the interior columns to a level with the cornice of the exterior order, and, as it is to be presumed that the portico was covered with marble slabs, like other structures of the kind at that period, it is obvious that the covering, with interior columns of the height given, would show from the front above the cornice. As this is hardly admissible, Mr. Harvey concludes that the interior columns, of which only the bases and a few fragments remain, were probably of the same height as the exterior ones, which would give them a proportion of nine diameters, and that they carried architrave blocks, at the same level with those of the exterior order, on which the marble ceiling slabs could rest safely; and this view is confirmed by the fact that an architrave block, apparently belonging to an interior order, still lies on the ground among the other fragments of the building.

MR. HARVEY, in speaking of other Athenian buildings, gives expression to a thought which has probably crossed the minds of many other architects, that the Greeks, notwithstanding their exquisite keenness of perception, and sense of beauty, did not always show that completeness of conception of their buildings which a modern architect regards as necessary, and which is so characteristic of the mediæval period. In the Theseum, as he points out, the columns of the porticos are laid out without any regard to the ceiling panels, and, in consequence, the marble slabs of the latter are sustained by stones placed almost at random, or, at least, corresponding neither with the colonnades nor with the walls of the cella; and, in order to find a support for some of these stones, it has been necessary to raise the ceiling of the western portico about eight inches above that of the lateral porticos. In the same way, the northern portico of the Erectheum, beautiful as every one acknowledges it to be, is longer than the front of the building behind it. The fact that this brings the opening between the two middle columns, and the door behind them, out of the axis of the main body of the temple would not, probably, disturb the Greeks, who did not care for exact symmetry; but, looking from the court of the Erectheum, which was open to every one, the misfit of the portico must have been painfully obvious.

THE University of Pennsylvania has come into possession of the first instalment of a collection of Babylonian inscribed tablets which promises to surpass in interest the famous collection of cones belonging to the British Museum. It seems that Professor Hilprecht, of the University, who has been making excavations at Nippur, in the Euphrates Valley, has come upon what seems to be a library, or storehouse of records, connected with the temple of the Sun in that city. These records are written on tablets, presumably made of soft clay, and burned, after being inscribed, like the cones used elsewhere in Babylonia; and Professor Hilprecht estimates that one hundred and fifty thousand of them are buried in the ruins of the temple. The tablets appear to date from the thirtieth to the fiftieth century before the Christian era, so that some of them, at least, must have been written long before Abraham was called from Ur of the Chaldees to the land of Canaan. In the case of the inscribed cones of the British Museum, nearly all the inscriptions so far deciphered are simply records of the transfer of real or personal estate, answering to our registries of deeds and mortgages, except that the Babylonians made records of transactions more trifling than those which usually appear in our registry-books; but the Hilprecht tablets may prove to contain matter much more interesting.

THE United States Bureau of Forestry is making rapid progress in systematizing the work which it has undertaken in response to the demand from citizens and municipalities for expert assistance. The former Section of Tree Planting has now been transformed into the Division of Forest Extension, and includes in its province the study of methods for encouraging the natural spread of forests. In certain portions of the West the timbered tracts, which occur mainly on the borders of the rivers, have extended two miles up the course of the stream within the past twenty-five years, and it is believed that a great deal can be accomplished by encouraging this natural forest extension. In the same way, forest tracts now sparsely covered with timber may, it is thought, be made more dense simply by preparing the barren soil between the trees for the germination and growth of the seeds which naturally fall upon it. Meanwhile, the interest of the public in the subject seems to have been thoroughly aroused, and the Bureau is busily employed in giving advice and assistance to people who wish to improve lands now barren. Among others, municipal Water Boards now show great interest in planting trees over the water-shed of their reservoirs. The Metropolitan Water Board of Massachusetts has already planted one hundred and seventy-five acres of new forest, and has young trees in readiness for planting a large additional tract this autumn. The Water Department of the city of Woonsocket, R. I., is also about to plant the territory under its control in the same way. As has been already noticed, several railroad companies have undertaken tree-planting on a great scale, and some of the Western colleges are setting a good example to the farmers of the neighborhood, as well as to their students, by experiments in forestry on their grounds.

ONE of the most interesting of modern engineering events is the definite opening of the electric railway from Le Fayet, or St. Gervais, to Chamonix. It is not long since Chamonix, although one of the most frequented spots in the High Alps, could be reached, except by pedestrians, only by a diligence journey of some fifty-seven miles from Geneva, or by carriage from Martigny or Vernayaz, over the picturesque but rather terrifying pass of the Tête Noire. Five or six years ago, the Paris-Lyons-Mediterranean Railway opened a line from Geneva, over the Chamonix road, as far as Le Fayet, the station for the Baths of St. Gervais. It will be remembered that a glacier torrent carried away, in the middle of summer, a portion of the great hotel of the baths, with its inmates, a few years ago, and a recurrence of the catastrophe was guarded against by the curious device of driving a tunnel, partly through the rock and partly through the ice, to draw off the glacier water harmlessly. From Le Fayet to Chamonix is only twelve and one-half miles, but the grades are so steep that it was impracticable to continue the railroad any farther, and omnibuses were provided by the Company to carry passengers the rest of the way. Now, the omnibuses have been superseded by the trains of an electric railway, which lands passengers at the lower end of the one busy little street of Chamonix, beside the path followed by parties ascending the Mont Blanc. So far as tourists are concerned, the two railways afford, perhaps, an agreeable change from the long and dusty diligence journey from Geneva, but those who have tried to find hotel accommodation in Chamonix during the busy season will understand that great changes must take place in the picturesque little town to provide for the increased travel. It is said that the electric road is to be extended through the valley to Argentière, and perhaps beyond, and this would do much to relieve Chamonix.

THE Prize of Rome in architecture of the Paris School of Fine Arts has been awarded to M. Prost, pupil of M. Lambert. M. Chifflot, pupil of MM. Daumet, Girault and Esquié, is First Second Grand Prize, and M. Coutan, pupil of M. Pascal, the Second Second Grand Prize. The programme called for a design for a National Printing Establishment, containing museums for specimens of books, printing-presses and so on; salesrooms for public documents and books on fine-art, which, it will be remembered, are usually published in France with Government assistance; a residence for the Director, with stables, state apartments and other dispositions suitable to an official of high rank; dwellings for the subordinate officials; and store-rooms, printing-rooms, binderies and other adjuncts of the manufacture of books.

DOMESTIC ARCHITECTURE IN ENGLAND DURING THE MIDDLE AGES.[1]—IX.

RECAPITULATION.

TO shortly recapitulate, on lines set out by Prof. Roger Smith, we may sum up the periods and characteristics marking the birth, development and decadence of mediæval architecture in England as follows: —

Romanesque and *Norman* prevailed during the eleventh and twelfth centuries, as previously illustrated and described at length in *American Architect*, No. 1328, page 76.

Characteristics: — Arches invariably semicircular. *Piers*, low, round and massive. *Windows*, very narrow and widely splayed internally only, as loop-holes for defence. *Doorways*, deeply recessed, becoming more and more enriched as the period advanced. *General construction*, essentially massive and wasteful of material, being hurriedly built for immediate defence against hostile surroundings.

Buttresses were broad, but of small and uniform projection. *Roofs* were low in pitch, covered with lead and used as a "fighting deck" for purposes of defence. Later in the period we find the *mouldings* enriched with the chevron or zigzag, the billet, chain, lozenge and nailhead; the capitals of the columns were decorated with incised ornamentation, made up of curved interlacing bands developed on a cushion-shaped bell; these enrichments are distinctive of the style and period, and entirely disappear on the advent of the pointed arch, they are never found on buildings erected subsequent to the close of the twelfth century.

Early English, or *First Pointed*, obtained during the thirteenth century, as previously illustrated and described at length in No. 1361, page 28.

Characteristics: — Arches, acutely pointed, lancet in form. *Piers*, slender in form, made up of clustered shafts, bound together by zones. *Windows*, broadly splayed internally, as before, but also splayed, slightly, externally; later in the period these single lights were grouped together in pairs under one arch, the pier between them being in still later cases reduced to a mullion (the inception of the Gothic window) and the overhead space filled-in with one stone, pierced with small circles (the inception of Gothic tracery), in which form it was called plate tracery. *Doorways*, deeply recessed, elaborately moulded, the dog-tooth and other conventional carving entirely replacing the decorations of the Norman period. In the capitals of the columns, a clear concave bell replaced the convex cushion, and was decorated by freely relieved conventional foliage of most distinctive character entirely replacing the incised decoration of the Norman period.

The *buttresses*, that before were plain, increased in projection by steps and stages and became prominent features. Gablets, carved finials and crockets appear as altogether new features. Flat wall-surfaces, as in spandrels, become decorated with relieved diaper patterns. *Roofs* gradually increase in pitch to the full equilateral triangle, the crenellated parapet forming the leading element of defensive architecture.

Decorated Geometric, or *Second Pointed*, flourished during the fourteenth century, as fully illustrated and described in No. 1364, page 52.

Characteristics: — Arches, equilateral in form. *Piers*, light, graceful and moulded, showing a general and marked advance in the art of constructive masonry. *Windows*, large, divided up into several lights by moulded mullions. These were continued up into the heads in geometric patterns, forming true (or bar) tracery of wonderful beauty. *Doorways*, enriched with figure-sculpture and carvings of natural forms and foliage, fully relieved, the distinctive conventional "ball-flower" replacing the earlier "dog-tooth" decoration in the hollow mouldings. In the capitals of the columns we find natural reproductions of the ivy, oak, maple and the forms of birds of wonderful sharpness that cannot be excelled at the present time.

Buttresses increase in importance, as leading features, as the walls become less massive in construction and the thrusts from contiguous arches become more concentrated. They increase in projection by numerous offsets, and stand aloft as counterforts decorated with canopies and figures, gablets, finials, crockets, more or less elaborately moulded and carved.

Roofs became of less pitch than in the previous period and they are often open to the framing and are panelled and moulded and decorated with carvings.

The pointed pointedness of the first Gothic, that replaced the round roundness of the Norman, became noticeably moderated in acuteness and more refined and cultured in all its details.

Perpendicular, or *Third Pointed*, flourished during the fifteenth century, as described and fully illustrated in No. 1369, page 91.

Characteristics: — Arches, becoming more depressed or obtuse, always less than equilateral. *Piers*, lozenge-shaped on plan, moulded and panelled. *Windows*, greatly increased in size and much subdivided, the main mullions richly moulded, carried up perpendicularly through the head, also divided in the height by transoms, forming several stories of lights, filled-in with richly colored glass in leaded lights in heraldic devices. *Doorways*, richly moulded, the outside mouldings carried up and returned over the head, enclosing spandrels decorated with cuspated panelling charged with crowns, roses, shields and armorial bearings.

Panelling, as a salient feature, is found as a surface decoration or enrichment, more or less elaborated, wherever it can be introduced. Fan-tracery in vault-groining, though not found in ordinary domestic work, is seen in the cloisters, the private chapels and chantries of the period, and is one of the special and most characteristic glories of the age.

Buttresses become excessively prominent, being bold in projection and carried high up as counterforts finished with dome-shaped turrets highly ornamented with panelling, carved crockets and finials, and decorated with fully relieved crowns, portcullis and armorial devices.

Open-timber *roofs* of moderate pitch and of the characteristic hammer-beam construction appear for the first time towards the close of the period, the timbers moulded and carved and the spandrels filled-in with open panelling, the roof-trusses carried on carved-stone corbels low down in the walls.

The *Tudor* style of architecture obtained during the sixteenth century under the princes of the Tudor line, as fully illustrated and described in No. 1374.

Characteristics: —Arches, four centred, and, in the latter part of the period, three centred or semi-elliptical. *Windows*, wide, still divided by numerous mullions and transoms, the traceried heads, the glory of the past, finally disappearing in the square-headed light, or lintel.

Doorways, moulded and outlined as before, plainer and less pretentious, the Tudor rose, the portcullis and fleur-de-lis being the most common forms of ornamentation. The general features in panelling, buttresses and roof-construction remained, but the richness of detail gradually disappeared and the simple architectural treatment of mediæval forms and styles gradually faded away into rapid incongruity and coarse, meaningless vulgarity. By the close of the sixteenth century all trace of mediæval art, as a living style of architecture, had ceased to exist; and, as the Classic styles of the Augustine period expired in the Dark Ages before the birth of mediæval art, so the latter disappeared in the political and social chaos that succeeded the great revival of letters of the sixteenth century. *Tempora mutantur, et nos mutamur in illis!*

THOS. C. SORBY.

[The end.]

[1] Continued from No. 1378, page 60.

"FIREPROOF WOOD," SO-CALLED.

FROM time to time during the last year several questions have been put to the undersigned and to Professor Norton in regard to fire-resistant materials on which our practice in dealing with slow-burning or mill-construction had given us no experience. From these questions originated the plan for the work in Insurance Engineering now in progress.

Among these questions were two upon which we now report.

The undersigned was asked, as President of the Boston Manufacturers Mutual Fire Insurance Co., what fire-resistant material would best serve for shelving a library. Professor Norton was consulted on the best method of constructing a fire-resistant and sound-proof partition for the separation of many rooms upon one floor, in each of which there might be constant practice in music, both vocal and instrumental, without such passing of sound as to be an annoyance or interruption. These two problems have been made the first subjects of investigation in Insurance Engineering.

Upon the question of shelving, which also covers door and window frames, dadoes, mopboards and other interior finish, much remains to be done. As yet our report must relate more to what is not fit to be used in a building which is otherwise constructed of incombustible material than of what is suitable and safe. On the negative side the evidence is conclusive that wood, whether treated chemically and called fireproof, whether painted with what are called fireproof paints, and unless covered with fire-resistant materials of considerable thickness, is unfit to be used for interior finish in buildings which are otherwise of incombustible materials.

We do not say fireproof buildings because the chief danger of destruction or great injury by fire comes from the burning of the contents of buildings of every type permitted under city building-ordinances, and not from the combustion of the material of the building itself.

Some of the so-called fireproof wood is less liable to rapid ignition and spread of fire from the immediate contact of flame than wood which has not been chemically treated. Wood which has not been chemically treated may also be in some measure protected from quick ignition and the rapid spread of fire by the so-called fireproof paints or, in warehouses for storage, by good whitewash or kalsomine. Wood or plastering of any kind, treated or untreated, when covered with any of the common varnishes, becomes a medium for the very rapid spread of fire originating from the smallest cause.

In dealing with shelving for libraries or museums, the new material known as uralite, not yet attainable, promises to be the most suitable and absolutely safe material at low cost yet known. It is hoped that large works corresponding to those now supplying Russia, where it was invented, and England, where a large supply is taken up for home use, will soon be established in this country.

The next feasible alternative seemed to be what is called "electric fireproof wood" or simply "fireproof wood." The undersigned had little confidence in the chemical processes to which wood is subjected in making it slightly fire-resistant or not quickly flammable, the treatment being old and well-known and, when revived under the name "electric," subject to greater suspicion, because electricity is not used in the treatment in this country. There is a process, of which we have information, now being applied in Germany in which an electric current is said to be applied for this purpose and of which we are promised samples.

In order, however, to remove all doubt, especially since these woods had been used in war-vessels and had been authorized under the somewhat stringent building-ordinances of the city of New York, it was decided to make the tests now reported.

A request was sent by the undersigned, as President of the Boston Manufacturers Mutual Fire Insurance Co., to the following six companies making so-called fireproof wood to supply shelves suitable for a library or museum of different kinds of wood: The Fireproofine Manufacturing Co., New York; American Wood Fireproof Co., Ltd., New York; New York Fireproof Wood Co., New York; The Electric Fireproofing Co., New York; Standard Wood Fireproofing & Chemical Co., Philadelphia; The Ignifuge Co. of America, New York.

Three companies complied with the request, namely: The Electric Fireproofing Co., New York; The Fireproofine Manufacturing Co., New York; Standard Wood Fireproofing & Chemical Co., Philadelphia.

Efforts have been made to induce the officers or agents to be present at the tests and to witness their impartial quality. This request was only complied with by one company.

Other experts in matters of insurance have been present and we have taken the opportunity to subject some other fire-resistant materials, which may be used for inside finish to the same tests at the same time.

We have been obliged to use rather small pieces in our present tests. As soon as we get the buildings up for the Experiment Station, a room of sufficient size within the walls of a concrete building will be placed at the disposal of the makers of fire-resistant material, where full-sized finish may be exposed to direct ignition from the contact of burning material; or, what is of much greater importance, to the high temperatures almost instantly generated from the combustible contents of mills, works and warehouses. The heat thus generated rises to the melting point of the fusible solder of the automatic sprinkler, 160 degrees Fahr., in 30 to 60 seconds; to the igniting point of fibres and untreated wood, 600 to 1,000 degrees Fahr., in two or three minutes; and often reaches the melting point of cast-iron, about 2,300 degrees Fahr., before the fire is extinguished.

Proofs of this report will be submitted to each of the three companies who have supplied the materials tested before going to press, in order to give them the opportunity to make any further suggestions that may be suitable, a final test after such submission being appointed for August 1, at 10 A. M., in No. 2½ Walker Building, Massachusetts Institute of Technology, at which final tests all the makers of so-called fireproof wood will be asked to be present in person or by attorney.

A doubt having been expressed by one of the principal promoters of the use of so-called fireproof wood, in regard to what he called our "theoretic methods" of dealing with the subject, he also stating that it was too late to question the "absolutely incombustible" quality of this product, as he had certificates to that effect from men of the highest scientific authority, I thought it best to make a practical test on my own behalf.

I therefore sent to my country house, where I have a large open fireplace, nearly half a bushel of blocks, split wood and shavings of all the types of fireproof wood yet submitted for testing, including black-walnut, poplar, pine and cherry wood. I first put upon the open grate a quantity of newspapers bunched up, in the hope of getting sufficient circulation to make newspaper burn. Upon this foundation we placed the fireproof material in the form of a cone, the preparation beginning at 8 P. M. We lighted the newspaper with a match, but found that the weight of the wood had crushed it together so that we could not get any good flame from the paper, the wood not being ignited. We then shoved more newspaper under the grate and used the bellows to keep the paper on fire, in which we succeeded, although it took some time. At 8.30 the fireproof wood was well ignited, showing a small flame of greenish-orange tint, from the distillation of the chemicals. At 8.45 the flames, first greenish and orange and then yellow, were from twelve to eighteen inches high, with a bed of hot coals underlying the flame. At 9 o'clock the flame had diminished. The mass constituted a very hot, glowing bed, burning more like coal than wood, with a little flame of the greenish tint upon the top, derived from small pieces which had fallen off at the beginning and had been placed upon the bed of coals. At 9 o'clock the mass was a bed of glowing material bearing no appearance to wood in the body of the fuel — much more like a hot coal fire. This form of combustion lasted until 9.30 P. M., when there was a small bed left about the size of the top of a hat. After that no further notes were taken. In the morning there was perhaps a pint or a little more of charcoal left upon the grate.

The theory of absolute freedom from combustion does not appear to be sustained by this practical test.

My own conclusion, from my observation of Professor Norton's work and the foregoing tests, is that the term "*fireproof*," applied to chemically treated wood, is a misnomer, tending to mislead persons not well informed upon the subject. The claim that any such wood is "absolutely incombustible" is without any warrant in fact. The chemical treatment works in some measure as a fire-retardent. The wood is less flammable from any direct contact with small quantities of burning material. Even if the heat from the burning of other substances partially ignites it, the fire goes out when the outside cause is withdrawn. On the other hand, if the so-called fireproof wooden finish of a building otherwise incombustible is exposed to a high temperature from the combustion of the contents of any room in the building, the chemicals will be speedily distilled; the so-called fireproof wood then becomes ignited and will continue to burn or the fire will go out substantially according to the kind of wood that has been treated. Many kinds of untreated wood, especially whitewood and other types of poplar, are difficult to keep on fire in their natural condition. The time and intensity of the continued burning in the case of both treated and untreated wood depends upon the kind of wood of which the finish is made and upon the draughts of air to which the burning material may be exposed. If any wood of any kind, treated or untreated, is used for the interior finish of a building otherwise of incombustible material, in the judgment of the undersigned, such wood should be encased in thin metal.

This conclusion is stated without consultation with Professor Norton on this point; he will give his own conclusions in his report without consultation with the undersigned.

During the progress of this investigation several materials have been brought to our attention which either are now made and offered for interior finish or soon will be. Preliminary tests of these materials will be made at the final test of the so-called fireproof wood, on August 1, which will be duly reported when the report of that final test is concluded. Respectfully submitted,

EDWARD ATKINSON, *Director.*

BOSTON, MASS., July 24, 1902.

SUPPLEMENTARY REPORT.

Copies of the foregoing report of July 24 and of Professor Norton's preliminary report of July 24 were sent by registered mail in proof-sheets subject to correction, to the representatives of the six companies named therein, with a request that they should make any suggestion, bring in new samples and be represented at the final tests, August 1, at 10 o'clock A. M.

In accordance with this notice, these tests were made and were witnessed by representatives of the Fireproofine Manufacturing Company, American Wood Fireproofing Company and the Ignifuge Company.

The following supplementary report is made, no reason having been given to change any part of the preliminary report made by the undersigned or by Professor Norton.

It should be stated that the only claim made, that the chemically treated wood is "absolutely incombustible," has been made in writing by only one company. The other makers of so-called fireproof wood do not claim absolute incombustibility, but only claim that their treatment makes the wood a fire-retardent.

Among others present were the following gentlemen: F. C. Schmitz, *General Manager*, the Fireproofine Mfg. Co., 66 Beaver St., New York, N. Y.; A. Eugene Kirby, *Secretary*, American Wood Fireproofine Co., Ltd. 156 Fifth Ave., New York, N. Y.; J. B. Peters, *President*, Ignifuge Co. of America, Holland House, New York, N. Y.; Perez M. Stewart, *Supt. of Buildings*, 220 Fourth Ave., New York, N. Y.; Rudolph P. Miller, *Chief Engineer*, Bureau of Buildings, New York, N. Y.; John Leo Jordan, *Ass't Supt. of Buildings*, 220 Fourth Ave., New York, N. Y.; Prof. Ira H. Woolson, Columbia University, New York, N. Y.; John S. Damrell, *Building Commissioner*, 14 Old Court House, Boston, Mass.; Greeley S. Curtis, Boston Fire Department, Boston, Mass.; Henry V. Thayer, *Inspector*, Boston Board of Fire Underwriters, 55 Kilby St., Boston, Mass.; C. J. H. Woodbury, 125 Milk St., Boston, Mass.; Franklin Webster, *Editor*, *Insurance Engineering*, 120 Liberty St., New York, N. Y.; Harry D. Cue, *Editor*, *Insurance Engineering*, 120 Liberty St., New York, N. Y.

All persons present were requested to take any exception to the methods employed, to suggest any other methods and to aid us in making this a final and conclusive trial on the merits of the wood. There was nothing developed which has led me to change any part of my own report previously given, or my own conclusions.

I should add that the fire-hazard of a steel-frame and concrete building is due to the high temperatures generated in the combustion of the contents of such buildings rather than in the flames which may be developed. It therefore follows that the greatest safety will be secured by not adding any combustible material in the construction of the building to the contents which are to be put into that building during its use. Therefore, while I might not, if asked as an underwriter, refuse to insure buildings finished with so-called fireproof wood at a suitable rate of premium, yet, if asked by the assured for advice in their construction, as we are asked by the prospective members of the Factory Mutual Insurance Companies how to construct their works and how to protect them, I should say that the building would be distinctly safer if no wood, treated or untreated, were used in the flooring or in the finish, or even in the doors.

We should, then, name several methods of covering the floors with incombustible material. We should, then, name several substitutes for wood, some of which can be moulded and made decorative for the interior finish of windows, doors, mopboards, etc. We should also name methods of making doors of a decorative kind which would be fire-resistant.

Time did not suffice to make even a preliminary test of several of these substitutes for wood which we have in hand. A complete test will hereafter be made of substitutes for wood for interior finish, of substitutes for boards or tiles for flooring, of fire-resistant doors moulded and decorated, of materials for shelving which will neither burn nor convey heat through their substance, and of outside applications for the treatment of wooden surfaces of various kinds. On all these subjects a separate report will soon be made.

There is also reason to believe that if some of these chemically treated woods, perhaps all, are exposed to a warm, humid atmosphere mould quickly gathers on the back of the finish, between it and the wall. This fungus may gradually destroy the cohesion of the wood and may be also of a very corrosive nature in respect to iron and steel. Tests will be made to determine these points which will require lapse of time for their development. Enough is known to warrant the caution not to permit any kind of a chemically treated wood to be placed in direct contact with any part of the steel-framing of a building.[1] The corrosive effect upon the carpenters' tools used in these tests bears witness to this danger.

In the body of this report I have suggested that if any wood is used for the interior finish of a steel-frame or concrete building, it should be encased in metal. I withdraw that suggestion in respect to the chemically treated wood, lest fungus or mould should be increased by the exclusion of the air. If wood in its natural condition is encased in metal it should be thoroughly seasoned, so that no ferment or dry rot, so-called, may occur. For a finish upon a wall the metal should be carried over the face, around the edges and ends and part way over the back of the finish.

The theory of the fire-door made of wood encased in tin which has long served as a fire-resistant in factory practice is, that while the wood may be slowly carbonized by the heat which passes through the metal, yet the exclusion of the oxygen prevents ignition and renders the door a heat-retardent so long as even the charcoal maintains its position, charcoal itself being a heat-retardent until ignited.

One architect in the city of New York has objected to the protection of wooden finish with a covering of thin metal, on the ground that, in case of a hot fire in the contents of such building, the metal would melt. The thin metal customarily used is a sheet of steel coated with tin, commonly called tin-plate. Any heat that would melt steel would consume unprotected wood in a few seconds, whether treated or untreated, and would wreck any steel-framed building protected by any covering yet devised.

Another architect objects to the wooden door encased in tin, on the ground that it will warp and curl, showing a strange lack of information in regard to common practice in factory construction and protection. The wooden door encased in tin has been adopted in order to overcome the danger of iron fire-doors, which almost invariably warp and curl. The wooden door encased in tin has invariably served its purpose in holding fire from passing from one room or one building to another until the fire-department could get the control of the fire in the building in which it has originated. The automatic fire-door of this description, first invented by the undersigned and since very much improved, is well known to all architects who have given attention to the prevention of loss by fire in factories and workshops.

EDWARD ATKINSON, *Director.*

BOSTON, MASS., August 6, 1902.

REPORT OF PROF. CHARLES L. NORTON.

The processes of "fireproofing" wood by saturating it with a solution which, on drying, leaves the pores more or less filled with crystals which, when heated, give out gases which retard the combustion of the wood, are not new. But the recent discussion as to the real value of such wood in modern buildings in case of fire, and as to the possibility of suitably sampling and testing the product before installing, has led to a series of experiments and examinations which it is proposed to report here. If "fireproof wood" were in any sense fireproof, this discussion would be unnecessary. It is not. It is similar to untreated wood except in three particulars: it is slightly less liable to be ignited by a brief and feeble application of heat; it is less likely to be ignited permanently by contact with a hot body, as an electric wire or a fragment of a projectile; and, further, it is not so likely to cause so rapid a spread of a fire in some cases, as it burns with less flame. "Fireproof wood" is almost identical with untreated wood in the following particulars: It smokes at about the same temperature. It can be ignited at about the same temperature. It will continue to burn in many cases. It is a good fuel. It makes a very hot fire.

The table of temperatures is given below: —

Kind of Wood.	Treatment.	Ignites at	Average.
1. Pine.....	None.	435° C. = 815° F.	
2. Whitewood.	None.	440° C. = 825° F.	
16. Cherry.....	None.	485° C. = 905° F.	840° F.
18. Maple.....	None.	440° C. = 825° F.	
19. Ash	None.	440° C. = 825° F.	
25. Pine.....	Electric Co.	505° C. = 940° F.	
3a. Cherry.....	Electric Co.	505° C. = 940° F.	940° F.
3. Maple.....	Electric Co.	505° C. = 940° F.	
4 and 4A. Whitewood.	Electric Co.	510° C. = 950° F.	
6. Pine.. ...	Fireproofine Co.	500° C. = 930° F.	
5. Whitewood.	Fireproofine Co.	500° C. = 930° F.	930° F.
8. Ash	Standard Co.	470° C. = 880° F.	
7. Cherry.....	Standard Co.	440° C. = 825° F.	
10. Maple... ...	Standard Co.	450° C. = 840° F.	850° F.
15. Whitewood.	Standard Co.	455° C. = 850° F.	

When exposed to a blast of hot gases, the amount of the treated and untreated wood consumed is about the same.

The wood examined was furnished by Mr. Edward Atkinson, as indicated by him in the earlier part of this report. Since these three kinds are apparently possessed of essentially the same characteristic, it will be assumed that they are representative of "fireproof wood," but the writer will be only too glad to limit his statements if he finds that any of the manufacturers who have failed to send us samples have an essentially superior article.

Examination was first made to see to how much higher temperatures the treated wood could be exposed than the untreated without its igniting or beginning to glow.

It will be seen that the average ignition temperature of the six untreated woods in 840 degrees Fahr., while that of the four Electric Company's woods is 940 degrees Fahr., while the Standard Company's six samples average 850 degrees Fahr., and the Fireproofine Company's two samples 930 degrees Fahr.

The value of the treatment is, then, to raise the igniting point less than 100 degrees Fahr., while some of the treated specimens show no sensible improvement. The data were derived from pieces $\frac{1}{4}'' \times \frac{1}{4}'' \times \frac{1}{2}''$, heated at different rates in a small electrical muffle, and the agreement between different samples was within 20 degrees. Twenty samples of each wood were tested and the results averaged.

It cannot, in view of these results, be claimed that the treated wood is sensibly less likely to be ignited when a temperature of 1,000 degrees Fahr. is reached.

The temperature at which the treated and untreated wood "flash," or flame instantly, was ascertained by putting a brass plate $\frac{1}{4}$ inch into the electric muffle and raising the temperature at a rate of about 5 degrees a minute until it was found that a piece $\frac{3}{4}'' \times \frac{3}{4}'' \times 2''$ burst immediately into flame on being thrown on to the brass plate. The flash-points are given in the accompanying table: —

Specimen.	Treatment.	Flashes in Muffle at Degrees Fahr.
1. Pine.....	None.	975°
2. Whitewood..	None.	950°
3. Maple.....	Electric Co.	1,140°
3A. Cherry.....	Electric Co.	1,140°
4. Whitewood..	Electric Co.	1,130°
4A. Whitewood..	Electric Co.	1,130°
5. Whitewood..	Fireproofine Co.	950°
6. Pine.....	Fireproofine Co.	960°
7. Cherry.	Standard Co.	1,015°
8. Ash.....	Standard Co.	1,015°
10. Maple..	Standard Co.	1,015°
15. Whitewood..	Standard Co.	1,015°

It should be borne in mind that any of the glowing wood may be fanned into blaze by a suitable draught or the burning of adjacent pieces.

The smoking temperature is not of material importance, but serves to indicate the similarity of behavior of the treated and untreated wood at low temperatures. The smoke, when mixed with air, is explosive, just as is the smoke from untreated wood. Further, the smoke and gases from the treated and untreated wood are alike liable to be ignited by a flame or spark, and cause the wood to be ignited when the wood itself is not yet heated to the ignition-point. The treated wood is less liable to this action, though I have seen it happen a number of times.

The extent of the relative destruction of the treated and untreated wood on exposure to the action of a flame at varying temperatures was carefully studied, with the results that are given below. They show that, with a blast of gas at a temperature of from 1,700 degrees Fahr. to 3,000 degrees Fahr. for 1, 2 and 3 minutes, the loss of a cross-section of a small specimen is from 5 to 12 per cent greater in the case of an untreated wood than in the case of the treated wood.

The table given below shows the diminution in cross-section in 3 minutes of several specimens $\frac{3}{4}'' \times \frac{3}{4}'' \times 6''$ when exposed to the flame of a blast-lamp.

Specimen.	Treatment.	Percentage Area burned.	Average.
Pine.....	Untreated.	64	
Whitewood....	Untreated.	62	
Cherry	Untreated.	48	
Maple.....	Untreated.	64	60
Black Walnut.	Untreated.	71	
Ash	Untreated.	54	
Cherry	Electric Co.	41	
Maple.	Electric Co.	45	
Whitewood....	Electric Co.	54	48
Pine.....	Electric Co.		
Pine.....	Fireproofine Co.	49	
Whitewood....	Fireproofine Co.	64	56
Cherry.....	Standard Co.	58	
Ash.....	Standard Co.	62	
Maple.....	Standard Co.	62	51
Whitewood....	Standard Co.	42	

If exposed to a hotter flame or for a longer time, the untreated wood more nearly approaches the treated wood in the amount of unburned area.

When subjected to the action of a powerful flame from a blast-lamp, the *rapidity* of destruction of a small test-piece also serves as an index of the value of the fireproofing as a preventive of combustion. Specimens $\frac{3}{4}'' \times \frac{3}{4}'' \times 6''$ and $\frac{3}{4}'' \times \frac{3}{4}'' \times 12''$ were supported in a horizontal position by the ends and a large blast-lamp placed under the centre. The time elapsing before the stick burned and fell apart was noted. There is no great difference between the treated and the untreated wood in this particular, the table below giving the average time required for a number of the specimens to burn through. It was noticeable that all the untreated specimens furnished more flame than the treated.

[1] A partial test not yet complete shows the tendency to mould in a very positive manner. (August 16.)

Specimens.	Treatment.	Average Time for Specimen to burn through.
Pine..	Electric Co.	6 minutes 35 seconds.
Whitewood.	Electric Co.	
Cherry.....	Electric Co.	
Maple.....	Electric Co.	
Ash	Standard Co.	6 minutes 18 seconds.
Maple.....	Standard Co.	
Cherry.....	Standard Co	
Whitewood.	Standard Co.	
Pine.....	Fireproofine Co.	6 minutes 22 seconds.
Whitewood.	Fireproofine Co.	
Pine.....	Untreated.	5 minutes 52 seconds.
Whitewood.	Untreated.	
Ash	Untreated.	
Cherry.. ...	Untreated.	
Maple.....	Untreated.	

The variation between individual specimens is very large, and the data on length of time required by a specimen to burn apart is only of value in showing again the similarity of condition of the treated and untreated wood.

The "hot-plate" test was next tried and showed clearly the characteristic tendency of the treated woods, when in isolated pieces, to char without much flame and to extinguish themselves when taken from the plate. The glow and flame last only a few seconds in the case of any of the treated woods, while they may last from 1½ to 2 minutes or may last only a few seconds in the case of untreated woods. This test demonstrates the value of fireproof wood as a safeguard against ignition from electric-wires in a certain sense, yet no "hot-plate" can compare in intensity with the incandescent metal and metallic vapor of many a short circuit. It is a good demonstration of the added safety of warships when finished with "fireproof" rather than natural wood, since one great danger of ignition in war-vessels is, I believe, from hot fragments of metal. In its general application to buildings this test demonstrates very little.

The tests which appeal most strongly to the writer are those which follow, and they are those which any architect may make for himself and judge for himself. These tests were made with the wood from each manufacturer separately. A furnace made of a half-dozen bricks and a 6-inch square of wire lath serves to hold a double handful of "fireproof" kindling. A piece 2 inches long sawed off the end of a board and then cut into pieces varying from ⅛ inch to ¼ inch square answers admirably for the fine kindling, being better than shavings. Add further a second double handful of little blocks ⅞″ x 1″ x 2″ or thereabouts. Apply beneath the grate a crumpled-up newspaper and a lighted match, and add rolled-up balls of newspaper as the first ones burn out, for a minute or so. The so-called fireproof wood will be harder to light than untreated wood; but, when lighted, you will make a good, lasting fire. In such a furnace, using treated wood for fuel, I have melted up several pounds of lead in a ladle and have then added larger blocks of the wood, ⅞″ x 2″ x 6″, and burned them up. As a final experiment, I have lighted such a furnace without any newspapers for kindling, but by the successive applications of some half-dozen matches. The fire, like any other, lights more readily and burns better if it is provided with a draught by means of a chimney, which may well be made of a length of tile-pipe.

One of my assistants, an excellent mechanic, substituted a bundle of about twenty sticks, ⅞″ x ⅞″ x 12″, in the kindling to be used by his wife in lighting the fire with which to prepare their breakfast. Although the major part of her kindling was "fireproof," the unsuspecting housewife made no comment, but made the fire as usual and burned up all the wood.

Noting the comment on the part of the manufacturers who saw my furnace glowing and flaming, that large pieces could not be made to burn, the following experiments were made: In a large fireplace, between two hard, dry pieces of pear-wood, 4 inches in diameter and 12 inches long, there was built a fire of newspaper and "fireproof" kindling; over this were laid on edge four boards (6″ x 24″, 8″ x 30″, 14″ x 20″ and 14″ x 30″) of "fireproof" wood, two from the Electric Company and one each from the Standard and the Fireproofine Company. The fire spread up and along the boards, and in about 2 hours the whole contents of the fireplace, except the pieces of pear-wood, were consumed. The two logs were all afire, but went out after the "fireproof" wood had been consumed. The room, in the meantime, had been rendered unbearably hot by the fire, which resembled a good cannel-coal fire in appearance.

One other experiment was made, to show how misleading is the test made by taking the wood out of the fire and noting how long it glows. A box, or pipe, 3 inches square and 36 inches long, open at the ends, was made of four different kinds of fireproof wood. This was held vertically over a blast-lamp until well afire at the bottom. The lamp was then removed, but the wood continued to burn until the box was much more than half consumed and fell apart, breaking into a half-dozen pieces. No one of the boards would have burned by itself nearly as much as it did when there was other heat near it — a condition, of course, which a fire in a building nearly always provides.

In the light of the results of these experiments, it would not appear that more can be claimed for "fireproof" wood than this: that, when heated, it gives off a gas which makes it more likely to fail to keep burning than an untreated piece of wood; and that, when afire, it gives out less flame, and hence is not as likely to cause fire to spread. It is not incombustible; it is not uninflammable; it is a good fuel; it will, under many conditions, support its own combustion; it is destroyed by external heat nearly as rapidly as is untreated wood. It is not as easy to work at high speed; it may cause rusting (as do some of these specimens), and the mechanical strength of the wood is slightly impaired. While it may be said to be an added safeguard to use this treated wood in tall buildings, it is so slight a safeguard as to be, in my opinion, of questionable value.

It should be borne in mind, too, that these samples, direct from the manufacturers, are of a certain standard of excellence which would hardly be reached in general without most rigid and expensive examination. I can suggest no sure method of examination of the wood furnished for a building which would be satisfactory and yet not inordinately expensive.

In consideration, then, of the physical properties of such wood as has been examined and of the difficulty of assuring one's self of the nature of the product; and further, in view of the possible deterioration of the wood or the fastenings and finish, the use of such fireproof wood in ordinary buildings seems of very doubtful value.

C. L. Norton.

Boston, July 24, 1902.

SUPPLEMENTARY REPORT OF CHARLES L. NORTON.

On August 1 a public test of so-called fireproof wood was held at the Walker Building of the Massachusetts Institute of Technology to demonstrate publicly some of the phenomena described in my previous report.

Specimens ¾″ x ¾″ x 6″ were subjected to the action of gas-flames of different intensities, and the percentage of wood consumed in 2 minutes, as well as the time to burn wholly apart, was noted. Next, a fire of bits of "fireproof wood" was kindled in a furnace made of half a dozen bricks by a lighted newspaper. Wood from the Electric Company, the American Company, the Standard Company and the Fireproofine Company was treated in this way.

The time required for the destruction of a small "cob-house" of treated and untreated wood was next determined. The little houses were built of sticks ¾″ x ¾″ x 6″ laid in nine layers of five pieces each, the adjacent layers being at right angles.

Upon applying a blast-lamp for 5 minutes, the treated house burned without much flame and at the end of 10 minutes, after the withdrawal of the lamps, the house fell. The untreated wood, when lighted in a similar manner, burned with more flame and fell at the end of 5 minutes and 20 seconds, the scattered pieces burning for a longer time than did the fragments of the treated house.

Next, four boxes, or flues, 3″ x 3″ x 28″ inside, without ends, were placed vertically over a blast-lamp until lighted at the lower end. Some half-dozen blocks ¾″ x ¾″ x 6″ were dropped in and held near the hollow of the flue by a wire grate. Three out of the four boxes continued to burn after the lamp was removed until they were burned through in places a foot apart.

A very extensive collection of pieces of "fireproof wood" from buildings now under construction in New York City has been examined in the same way as have the samples already described. They behave in a manner much like the earlier samples, but are slightly more flammable, and they are not as uniform in treatment throughout.

Respectfully submitted,

Charles L. Norton.

Boston, Aug. 8, 1902.

A BRITISH REPORT ON OUR IRON TRADE.

THE phenomenal development of the iron and steel industry of the United States led the British Iron Trade Association to appoint a commission last year to inquire into the industrial conditions and competition of the United States. The report of that commission, which has been recently presented, is briefly reviewed by the *London Commercial Intelligence*, a copy of which has just reached the Treasury Bureau of Statistics. It says: —

"It is, indeed, a marvellous and, to the British manufacturer and trader, in some respects a most discouraging story. The British Iron Trade Commission gives details of the mineral resources of the United States as affecting that fundamental industry — the manufacture of iron and steel; shows the extraordinary richness of the principal fields of coal, iron-ore and kindred minerals and demonstrates by concrete examples how the natural inventiveness of the American has enabled him to apply to the operations of production and distribution a wealth of original ideas and methods that are as yet little known in Europe. It is also made manifest how on land, on lake, on river and on canal, the American people have applied their minds to the solution of the conditions and problems of cheap transport until they have at last attained a level of rates and charges such as we have hardly had any experience of on this side of the Atlantic. It is not, however, to be supposed that the triumphs of the American people in these matters have been achieved without effort. Much testimony is borne to the fact that in the conditions of organization and administration in their dealings with labor, in the confidence and enterprise with which they have embarked on industrial operations of great magnitude, in the efforts made to adapt themselves to new conditions, in the eagerness with which they have endeavored to create new demands both at home and abroad, and in the care and attention given to the successful cultivation of foreign markets, the American people have labored strenuously for many years, until labor, ingenuity and enterprise have become their most distinguishing characteristics. When one has appreciated all that the Americans have done for themselves, it is neither natural nor

reasonable to grudge them the success which has attended their labors."

Commercial Intelligence presents the following picture of the relative growth of the iron and steel industry in the United States and the principal countries of the world: —

PRODUCTION OF PIG-IRON IN THE UNITED STATES, UNITED KINGDOM, GERMANY AND ALL OTHER COUNTRIES, IN GROSS TONS.

Year.	Tons.			
	United States.	United Kingdom.	Germany.	All other Countries.
1865	832,000	4,819,000	760,000	2,839,000
1870	1,668,000	5,964,000	1,369,000	2,902,000
1875	2,024,000	6,365,000	1,997,000	3,510,000
1880	3,835,000	7,749,000	2,686,000	3,201,000
1885	4,045,000	7,415,600	3,629,000	4,439,000
1890	9,203,009	7,904,000	4,585,000	5,738,000
1895	9,446,000	7,703,000	5,379,000	6,376,000

CHRIST CHURCH CATHEDRAL, OXFORD.

ANTIQUITY, architecture, great traditions, distinguished alumni, and church music form a combination of characteristics which invest with peculiar interest the great College of Christ Church in the University of Oxford, says a writer in the *Musical Times*. In regard to antiquity, a Saxon church which formed part of the monastery of St. Frideswide, *circa* 727, stood on the site of the present Cathedral. Commenced in 1120, and consecrated sixty years afterwards, the buildings forming the Chapel of Christ Church, otherwise the Cathedral of the Diocese of Oxford, are rich in architectural development — the Norman of the main sanctuary, the Early English of the Chapter House, and the Perpendicular of the Refectory, now broken up with rooms, but preserving the exterior windows on one side. Its spire, though appearing somewhat dumpy in this "sweet city of dreaming spires," is one of the earliest — if not actually the first — built in England. The fact that Christ Church is one of the smallest of our cathedrals is partly due to Cardinal Wolsey, who chopped off, so to speak, three of the westernmost bays of the nave in order to make way for the celebrated Tom Quad.

In recent years the Cathedral has been lengthened by a new western bay forming an ante-chapel. The interior has several features of interest. The Lady Chapel and the Latin Chapel — a church within a church — both situated at the northeast of the choir, give the Cathedral a peculiar shape. Moreover, the choir and the nave are not separated. At the east end are three extremely rough arches, leading to three semicircular apses, of which the foundations still exist, discovered in 1888, and which remain as relics of the first stone church of St. Frideswide, one of the earliest stone churches in England. The thirteenth-century shrine of St. Frideswide attracts attention no less by its beauty than for its historical associations. In the choir may be seen traces of Ethelred's work in the large round pillars and the weathered columns above, that once formed part of the clerestory. One of the oldest Members of the House, Mr. T. Vere Bayne, has lately resolved to replace the curious corner turrets of the west end at his own private cost. The pulpit, surmounted by a pelican, and the organ case, are of the Jacobean period.

The reverent restoration of the Cathedral, first instigated in 1856 by Dean Liddell, included the successful rebuilding of the east end, said to be a reproduction of the original twelfth-century design, and is a testimony to the labor of the late Sir Gilbert Scott. As showing the utter lack of reverence in the "good old days," as they are so often misnamed, it may be mentioned that previous to 1870 one bay of the south transept served as the residence of the Dean's verger. This functionary, a Mr. Keys, kept his beer-barrel in a cupboard just below the pew in which the deanery ladies sat! Moreover, Verger Keys used to station himself at the entrance of the choir armed with a stout dog-whip, with which to belabor any of the canine tribe that not infrequently followed their undergraduate masters into chapel. If the chapter-books are not profuse in reference to the Cathedral, they furnish evidence of the rich ornaments that even survived the confiscation (*temp.* Henry VIII) of "monuments tending to idolatrie and popish or devill's service, crosses, censars, and such lyke fylthie stuffe."

One of the earliest chapter-orders enjoins that "the Orgaines in the Quire of this Church be taken downe." Father Smith built an organ of two manuals in the year 1680. The organ has occupied various positions at different times. In 1806 the organ-loft was "fitted up so that the singing boys and singing men may be removed thither for the future." The present organ — located at the west end of the nave, its key-boards approached by an iron spiral staircase — is a four-manual instrument, rebuilt in 1884 by Father Willis. In any scheme of reconstruction, now necessary after the wear and tear of eighteen years, the choir-organ should be restored to its original "in front" position, where it remained for nearly two centuries, in order that its stops may form a better support to the voices than is possible under the present arrangement.

SPANISH ARCHÆOLOGY. — The city of Barcelona offers a prize of $4,000, due in 1906, for the best work on Spanish archæology. It may be written in Latin, Spanish, Italian, French or Portuguese. —*Exchange.*

THE GERMANIC MUSEUM, NUREMBERG.

IN the New York *Evening Post* Kuno Francke says that "For more than twenty years Baron von Aufsess, the virtual founder of the Museum, wrote, labored, begged, and spent his own means for this project without obtaining any help or recognition from any quarter, without meeting with anything but ridicule or indifference, or at best half-hearted and lukewarm interest. And even when at last, in 1852, through the vote of the Historical Congress referred to, the establishment of this Museum, with Aufsess as its director, was decided upon and made a matter of common scholarly concern, the means at the disposal of the young institution were so slender that for years to come it was continually on the brink of disaster, and required constant financial sacrifices on the part of the director to be barely maintained.

"Until 1857, most of its collections were housed in a single tower of the Nuremberg city-wall, the Thiergärtner Thor, and the accommodations for accretions were so ridiculously insufficient that, for instance, when in 1853 the official records of the Frankfort Parliament were presented to the Museum, the twenty-three boxes containing this valuable gift had to be stored in the kitchen of a private house. It is to Aufsess's lasting credit that, in all these straits, difficulties, and disappointments, he never lost heart, always stood by the great ideal of his life, and thus weathered one crisis after another, until at last, through the acquisition of the old Carthusian monastery from the Bavarian Government, a proper housing for the growing collection was obtained, and popular and official interest in the national undertaking permanently secured. That this noble, patriotic man should have met with his death at the hands of a drunken student when, in 1873, he had gone to take part in the festivities attending the foundation of the University of Strassburg, gives to his life a touch of the irony of Fate.

"It was, however, not only the memory of the founder of the Germanic Museum which actuated the festivities of last month. They were also meant as a tribute to what the German people has done for this museum since it was once publicly recognized. It is not an empty phrase when, over the main entrance of the Museum quadrangle, there stands the inscription: 'Eigentum des deutschen Volkes.' Here we tread, indeed, in more than one sense upon national soil. Ever since 1857, when the institution was first housed in a manner suited to its intrinsic importance, it has stood before the public eye as a symbol of German greatness, as an embodiment of the most precious traditions of the German past, and as an appeal for maintaining these traditions in the present. Princes, states, cities, and private individuals have vied with each other in showering gifts of objects as well as of money upon it, the latter ranging from five florins collected by the pupils of a Bavarian seminary — the very first contribution made to the Museum — to the million marks which were given by two Nuremberg citizens a few weeks ago as an anniversary donation. And it would be hard to conceive of a more widely diffused popular interest in a scientific institution than that maintained in this museum by the network of so called *Pflegschaften*, or chapters of the Museum Association, covering all Germany, each of which is constantly disseminating, within its local boundaries, information regarding the needs as well as the most recent acquisitions of the Museum, and is thus stimulating ever new endeavors in its behalf. It is largely owing to this finely systematized popular propaganda that, apart from the running expenses of the Museum administration, which are covered by yearly appropriations from the German Empire, the Bavarian Government, and the city of Nuremberg, all other financial costs, for purchases, building alterations, special investigations, and so forth, are defrayed by voluntary contributions coming from every class of people and from every part of Germany."

NOTES AND CLIPPINGS

THE BRITISH ACADEMY. — King Edward has granted a charter incorporating the new British Academy for the Promotion of Historical, Philosophical and Philological Studies. The charter names 49 original fellows, including Lord Rosebery, Prime Minister Balfour, Lord Dillon, President of the Society of Antiquaries; Lord Reay, President of the Royal Asiatic Society; James Bryce, William E H. Lecky, John Morley, Sir Frederick Pollock and Leslie Stephen. This, together with the creation of the Order of Merit, is regarded as a striking experiment, and has provoked comparison to the French Academy, which has failed to enroll many of the greatest names in French literature. Members of the British Academy are to be called simply "fellows," instead of "immortals." Both Cambridge and Oxford are represented among the charter members, but a notable omission is Herbert Spencer.— *Exchange.*

AN ICELESS REFRIGERATOR. — An iceless refrigerator has been invented by an Oregon man, in which the principle of the evaporation of water to reduce temperature is used. According to the inventor, the iceless refrigerator presents much the same appearance as do ordinary refrigerators. The outer casing and door may be made of plain or expensive woods, as taste may dictate. The upper half and the top are closed tightly. The lower portion is formed of inclined slats, through which air may be freely admitted. The door is also made tight at the top, and provided with slats at the bottom. The interior frame is made entirely of galvanized iron to prevent shrinking and expanding or becoming mouldy with constant dampness, and it is also a good conductor of heat, and, therefore, assists in reducing the temperature lower than it could otherwise be maintained. Burlap or other fibrous material is fastened upon this inside frame so as to form an interior wall, which stands at a sufficient distance from the outer wall of the structure to form an annular space between the two. In the top of the inner structure is an opening covered with screen material. Through this and the slats around the bottom of the outer casing a constant draught of air passes, thus causing an evaporation of moisture, with which the fibrous material is saturated, so that the interior of the apparatus is maintained at a low temperature. All around the top of this frame is a strip of galvanized iron, with an inclined lip bent over. The edge of the burlap is fastened upon the face of the frame, one-eighth of an inch above the edge of the lip, so that the water which is discharged upon this inclined surface will not flow over the burlap, but will be directed against it, so as to be absorbed, thus saturating the burlap. The fastening for this burlap or other fibrous material consists of a double-pointed tack or holder, the head of which is soldered or otherwise secured to the face of the galvanized iron. The fibrous material being pressed over the points, they are folded down to hold it in place. This renders it easily removable for change or cleaning. Above the top of the frame is a tank for holding water. Projecting from the sides and ends of this tank, and at a suitable distance apart, are horizontal pipes having in the outer ends vertically disposed needle valves, which control the flow of water from openings in the lower parts of the pipes. These openings and controlling valves are situated in line above the slanting lips, so that water delivered from the openings falls upon the lip and flows down into the fibrous material, keeping it constantly saturated. — *N. Y. Evening Post.*

URALITE, A NEW FIREPROOFING MATERIAL. — Uralite, a new fire-resisting material for constructional purposes, originally invented by Colonel Inchenetski, a Russian artillery officer, and since greatly improved by the British Uralite Company, was subjected to somewhat severe tests on Wednesday at the Company's works, near Rochester, Kent. In its manufacture asbestos from Canada, the United States, and the Ural Mountains is ground to pulp, and mixed with about 30 per cent of chalk to fill up the interstices between the short fibres, and, after going through a number of chemical processes, appears in the form of tough, pliable strips. Finally, gelatinous silica is used for cementing purposes, about 20 per cent being required, and this combines with the 30 per cent of chalk, and some 50 per cent of asbestos, in making boards of uralite which are stiff, will stand a great amount of wear and tear, and, above all, are impervious to fire. A deed-box, constructed of wood, and lined with uralite, one soft layer of which separated two layers of wood, while two more layers, one soft and one hard, covered the inside and outside, was placed on iron standards inside an iron-framed hut, covered, and lined with uralite. A fierce fire was kindled, the temperature inside at one time reaching 2,030 degrees Fahr., and after being left over half an hour, an examination was made. It was found that the wood nearest the fire was charred right through, but the middle uralite was sound. The outer layers had porcelained, and were badly cracked. Papers placed inside were slightly discolored, owing to distillization, but were not charred. Sulphur and fusible metal placed within crucibles were unchanged, a portion of paraffine wax in another crucible alone having melted. Another test had for its object the trying of what various pattern doors fitted into a brick hut would stand. A fire was ignited inside, and the doors were closed, and left so, over an hour. The highest temperature at one time was 2,350 degrees Fahr. As a result, one door of two layers of uralite running throughout, and forming the panels, with a framework of timber on either side, was penetrated by flames after some time, which was not surprising, considering its slight structure, and most of the wood was charred off. The uralite, however, stood. Another door of two layers of oak, separated by uralite, with two layers of the same material without and within, proved impenetrable, the inner layer only being cracked and porcelained. This was intended to represent a warehouse door. Two other doors were equally successful, a sheet of tin in one only being slightly buckled. In the case of two sections of platform, one of wood only, and the other of wood cased with uralite, the former was rapidly eaten away by the flames, while the latter was, at the end, quite strong. Subsequently, the various processes were explained, and it was shown that uralite can be painted, and will take a wood veneer, which will not warp or crack, and is about one-fifth of the weight of its own size in corrugated iron. — *Insurance Observer (London).*

ALUMINIUM AS A SUBSTITUTE FOR COPPER. — The possible substitution of aluminium for copper in electrical work is a question which has been discussed from time to time in the press; frequently, we regret to say, by writers who apparently know very little about the facts. It has also been referred to by electricians, some of whom have been able to speak from actual experience. From the expert testimony it appears that aluminium can be and has been used for conducting purposes in power-plants and for the transmission of power from such plants. The most notable employments of the metal for the former purpose have been in some of the recent installations at Niagara and in some California plants; for the latter at Snoqualmie Falls in Washington, and the Blue Lakes power-plant in California. Notes of these uses of the metal have appeared in our columns from time to time; and its use at Blue Lakes was fully treated by Dr. F. A. C. Perrine in a paper read before the Institute of Electrical Engineers. The testimony of experts is that aluminium has given good results where it has been used; and that its lesser conductivity, as compared with copper, and its lower tensile strength, requiring the use of bars and wires of larger section, are so balanced by the low specific gravity of the metal that in the matter of cost aluminium at its present prices is about equal to copper at 16 to 17 cents a pound — that is, at present prices. For transmission wires there still seems to be some doubt whether, in a northern climate, aluminium wires will stand the stresses of snow, ice and high winds as well as copper. In a milder climate this consideration might be disregarded. It may be assumed, therefore, that it would be possible to substitute aluminium for copper in electrical work to a considerable extent — provided the metal can be had in sufficient quantities for the purpose. That is, after all, the most important question. For all immediate purposes the question seems to be answered by the fact that in 1900 the total production of aluminium in the world was 5,570 metric tons, of which the United States furnished 2,053 tons; while that of copper was 492,625 metric tons, of which 272,536 tons were supplied by this country — that is, the total output of aluminium last year was only 1.1 per cent of that of copper. Until these figures are greatly changed, the competition of aluminium is not likely to affect the copper market. The price of aluminium at present is — as above stated — about on a par with that of copper, allowance being made for the respective weights. The aluminium quotations, however, have not been regulated by those of copper, but have been based, as we understand, upon the cost of production. They have shown little change during the past year. There is no competition tending to lower them; but on the other hand it is to the interest of the producers to keep them as low as possible in order to dispose of their output. The main point to be considered, therefore, is to what extent the production can be increased. There is a general indefinite idea prevalent that as alumina is so abundant and so universal in its occurrence, it ought to be possible to extend the extraction of its metallic base indefinitely. That this is not the case is shown sufficiently — without going into details — by the fact that present production is so small, although the best metallurgical skill has been for years concentrated on the problem of separating the metal. We do not mean to say that cheaper and more expeditious processes of furnishing aluminium may not be discovered hereafter. That is a problem which may be worked out by some investigator to the great benefit of the world — and himself. It has not been done yet, and considering present conditions, as we must, we are unable to see any opening for the substitution of aluminium for copper — or for any other metal — on a commercially important scale. — *Engineering and Mining Journal.*

AN UNVERIFIED PREDICTION. — In the *Anti-Jacobin Review* (English) for 1800, may be found the following flouting of the new capital city of this country: "The seat of the Federal Government is this year to be removed into a wood in Maryland, called the city of Washington. From the 'Capitol' of this city, one wing of which is, we are informed, so far finished as to be fit to receive the Congress, the members must go 4 miles to a little place called George Town, to their lodgings! Some people suppose that when the Government retires into this desert, it will, like the Grand Lama, be adored, because it will never be seen; others suppose that the spot will soon be rendered rich and populous by the vast concourse of pilgrims who will, doubtless, flock to the tomb of General Washington, whose body is to be removed thither from Mount Vernon; there are, however, others who, far from having any hopes of this sort, scruple not to aver that if anything would hasten the downfall of this tottering fabric of a government, it certainly would be the ridiculous removal in question."

LANDSEER'S AMBIDEXTERITY. — Mr. Conrad Cooke, son of E. W. Cooke, R. A., tells me that he used to hold the paper while Landseer drew one animal with his right hand and a different animal with his left, writes Mr. J. A. Manson in "*Sir Edwin Landseer, R. A.*" This species of dexterity comes from practice, no doubt, and is akin to the adroit manipulation of the accomplished pianist, but is nevertheless extraordinary, and several cases are recorded in which Sir Edwin fairly astounded the onlookers by such displays of manual skill. — *Exchange.*

When do Building Operations begin? 88
NOTES AND CLIPPINGS. 88

THE unfortunate controversy, with which our readers are only too familiar, between Mr. Addison Hutton and the Philadelphia Chapter of the American Institute of Architects, has ended in the defeat of the latter, which is commanded by the Pennsylvania Court of Common Pleas to restore Mr. Hutton to membership, and to the privileges which he formerly enjoyed as a member of the Chapter. After the original competition for the State Capitol at Harrisburg, in which the profession was treated with such conspicuous bad faith, and after Mr. Cobb, who had been employed, in violation of the terms of competition, and of the law, had been, in his turn, ignominiously dismissed, a second competition was instituted, confined to Pennsylvania architects, for plans for the completion of the building upon the foundations already put in by Mr. Cobb. The Philadelphia Chapter, the members of which have long been distinguished for their unselfish and intelligent devotion to professional interests, denounced the new competition, by resolution, as "calculated only to encourage favoritism and injustice," and advised all Pennsylvania architects to refrain from entering the contest. Mr. Hutton, a member of the Chapter of long standing, submitted competitive designs, notwithstanding the action of the Chapter, and was, in consequence, expelled from membership. He applied to the Courts for reinstatement, and was successful, the Court holding that the powers of the Chapter were strictly limited by its charter, and that the charter did not provide for the expulsion of members for such offences as that charged against Mr. Hutton.

WE may as well say frankly that we are pleased at the result of the suit; not from any unfriendliness toward the Chapter, for the members of which we fully share the gratitude and esteem generally felt in the profession; but because the fact that a corporate body cannot legally exceed the rights conferred by its charter needs to be brought to the attention of professional associations. Societies of architects are not more free than others from the temptation, in the heat of controversy, or in their zeal for the defence of professional rights, not only to overstep their legal powers, but to pass resolutions, or take measures, which, in cooler moments would appear less justifiable. In the case of Mr. Hutton, the question whether disloyalty to the expressed sentiment of his Society would, in the abstract, justify his expulsion might admit of an interesting argument; but it is certain that it did not legally justify such action; and the same principle will apply to occasional acts of professional societies, which middle-aged architects will remember, in favor of which much less can be said than in this case. So far as Mr. Hutton is concerned, it seems to us that the result of his contest ought to be to reinstate him actually, as well as legally, in his position in the Chapter. It is, indirectly, an honor to the Chapter that he valued his membership in it so highly as to be willing to engage in a costly lawsuit to compel reinstatement; and, while so many causes are mentioned in the Charter for the legal expulsion of a member, the fact that he did not fear the application of any of these to justify the action of the Chapter speaks strongly in favor of his worthiness to be associated with it.

WITHOUT entering into political questions, which are not our province, it may be observed that the reduction or abolition of the duty on lumber, which seems likely to be the first step in any process of tariff remodelling undertaken by either party, will have an important effect upon the building industries everywhere in the Northern States. The New York *Times*, which although opposing high tariff, is usually conservative, mentions its "surprise that the voice of that section [New England] has not found expression in an emphatic demand for a lower range of duties on raw materials, which would put its manufacturers on a plane of equal advantage with those of other sections, with which they are now maintaining an unequal competition." Although New England has not yet shown any signs of carrying out the suggestions of the *Times*, several of the Western States, through their Republican political conventions, have pronounced in the strongest manner in favor of the repeal of the duties on lumber; and certain influential Republican Congressmen have secured a renomination only by pledging themselves to propose, and work for, the abolition of these duties in the next Congress. Whether their efforts will, or should, be effectual we do not undertake to say; but if they should, the result would inevitably be the pouring of vast quantities of Canadian spruce into our Northern States, at prices so much lower than those now paid that it will be for the interest of every one who contemplates building a house to begin operations at once. We are accustomed to speak of the "inexhaustible" spruce forests of Canada, but the fact is that those forests are very far from being inexhaustible, and Canada itself is developing with such rapidity that its consumption of timber is already very large; but there is enough timber to supply both countries for years to come, and the inevitable ultimate rise in price will hardly affect the present generation.

SOME student of American politics might find edification in the investigation of the political aspects of the strike in the anthracite region. There have been many circumstances connected with the strike incomprehensible to the general public, but pointing more and more clearly, as they accumulate, to a secret understanding between the leaders of the strike and certain politicians, which, if not the direct cause of the contest, has had the effect of encouraging and extending it. It will be remembered that, at the outbreak of the strike, as soon as it appeared that the operators were determined to resist the demands of the unions, there was a rush of prominent politicians to Pennsylvania. One of these gentlemen is said to have told the obdurate operators that unless the strike was speedily settled, the next Governor of Pennsylvania would be a Democrat; and distinguished Republican Senators and Governors, although they have not been quite so indiscreet, have been conspicuous ever since in their efforts to compel "arbitration" of the trouble, the Governor of Pennsylvania having recently announced his intention of calling an extra session of the Legislature, and, if necessary, of having the Constitution of Pennsylvania amended, so as to put it in the power of the Executive to enforce arbitration.

IT is not likely that all these expressions are mere incoherent ravings on the part of such sensible men as Senators Hanna, Quay and Penrose, and Governor Stone, and a reference to past history may show reason and consistency in them. A year or so ago, as every one recollects, there was a serious strike in the bituminous-coal region, led by the same John Mitchell who now directs the strike of the anthracite men. The conflict reached such a pitch that the attention of the country was aroused, when, just at the critical point, Senator Hanna was put forward as a peace-maker. An interview was arranged between him and Mr. Mitchell, and, as a result, a

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

friendly understanding was arrived at, the strike was called off, and everybody was happy again. The tact and diplomatic talent of Senator Hanna won deserved praise, and a Civic Federation was almost immediately formed, composed of distinguished divines, authors, "captains of industry," and others, intended to prevent all strikes in the future, by interposing its good offices for arbitration or settlement. Senator Hanna was made the Chairman of the Federation, which, as has since been remarked, did not contain a single representative of the anthracite interests, although the bituminous mines were represented.

IT would probably be unfair to the parties concerned to assume that a scheme had been formed to control, by means of Mr. Mitchell, the votes of the one hundred and forty-eight thousand men employed in anthracite mining, in the interest of a certain party, and its nominees, but it is not unlikely that Senator Hanna and his friends knew that, by favoring Mr. Mitchell's plans, they were establishing a substantial claim upon his gratitude. However that may be, the Civic Federation had not existed many months before Mr. Mitchell, with whom Senator Hanna had found it so easy to adjust the differences in the soft-coal region, appeared with a virtual demand to be placed at the head of the anthracite miners also, and to be armed with what Mr. Hewitt calls the "power of life and death" over their actions. By his own statement, Mitchell was never in an anthracite mine but once in his life, and his claim to authority over the anthracite miners seems to have rested solely on the influential support which he had gained. To the surprise, apparently, of his backers, the anthracite operators resisted. Senator Hanna was at once called in, without avail, and the machinery of the Civic Federation was set in motion, also to no purpose. Then began the singular allusions to the political importance of a speedy settlement, the outcries of partisan Republican newspapers for "compulsory arbitration," the predictions of disaster to the party unless the power of the Commonwealth of Pennsylvania were applied to the coercion of the operators, and the rather unaccountable actions of Governor Stone, which have now begun to show a certain consistency with each other, and with the events of the previous year. Meanwhile, the strike has resolved itself, not so much into a struggle between the operators and their men, as into one between the operators and a small clique of schemers, who are trying to distress the public, by cutting off the supply of coal, into support of their plans. In this attempt they are greatly assisted by a law of Pennsylvania, enacted some ten or twelve years ago, obviously in the interest of the union managers. Under this law no one can work as a miner in any anthracite mine in Pennsylvania, under penalty of a heavy fine, or of imprisonment, unless he holds a certificate, issued by a Board of Examiners, certifying, not that he is competent and intelligent, but that he has been employed in an anthracite mine for at least two years. The statute also forbids any person or corporation, under severe penalties, to employ any one, not furnished with a certificate, as a miner in any anthracite mine in the State, and provides that a register shall be kept of all certificated miners in every mining district. Even if the interest of the operators in having their work done efficiently, and the knowledge of their responsibility for accidents due to the incompetency of their men, were not sufficient to insure the employment of capable workmen, it is absurd to suppose that the mere fact of having spent two years in a mine would make a good man out of a vicious and stupid one, or that an intelligent and ambitious man could not learn so simple a trade in less than two years if he tried; and the evident interest of the statute is to play into the hands of the labor agitators, presumably in return for some promised equivalent, not only by encouraging and supporting strikes, through the almost insurmountable obstacle which the two-year clause places in the way of the employment of new men to take the place of strikers, but by placing in the hands of the union tyrants, through the registration lists, the means of pursuing, and bringing into the fold, one by one, all the certified miners in Pennsylvania. In this manner the way has been prepared for the grand struggle, which is now in progress, to subject the whole population of the coal-mining districts of the country to the dictation of a group of plotters; and the people who are now sadly wondering how they can get their coal-bins filled for the winter, or where they can get the money which will be required for filling them, may with advantage reflect that they are only paying, or will soon have to pay, the tax which, in the end, honest and simple people always have to pay for bad legislation, political trickery and industrial tyranny.

THE strike itself seems just now to be slowly disintegrating. Thousands of men are ready to labor in the mines, and would long ago have been at work, except for their fear of being assassinated by the ruffians who, as the newspapers inform us, are permitted, in the States of Pennsylvania and West Virginia, to surround at night the houses in which the new men live, and riddle them with rifle-bullets. Meanwhile, the leaders of the strike, with characteristic treachery, have, it is said, coolly abandoned more than a hundred thousand firemen, shovellers, laborers, hoisters and others, whom they induced or compelled to strike, in order to cripple the mines as completely as possible, and are distributing the money which flows in from assessments and contributions exclusively among the forty thousand members of the miners' union, leaving their allies and supporters to starve. It is more than likely that the strike managers count upon the deeds of violence which these poor creatures, prevented from going back to work by fear of assassination, as well as by their blind sentiment of loyalty, will commit when driven to desperation by the sight of the sufferings of their wives and children, as a means of influencing the public in support of their schemes; and the public should be careful not to be misled any further than it has already been, by cold-blooded plotters, at the same time that it should look with the charity which is quite consistent with firmness upon any excesses of the poor and ignorant, but not wilfully vicious, people who are the worst sufferers in a struggle apparently undertaken in the interest of heartless ambition.

THE new art, in architecture, seems to have received what may be called its official consecration by the award of a premium in the annual competition of the Société Centrale des Architectes for executed house-fronts to an advanced specimen of the new style, by M. Lavivotte, in the Avenue Rapp. The front is mostly in colored tiles, with a backing of armored concrete, a construction which permits the use of wide arches without any appreciable abutment, and other forms which would be of doubtful stability in ordinary masonary. In detail, the front is a tolerably extravagant specimen of the style of design which, as a distinguished French critic says, appears to be founded on the contortions of a worm that has swallowed a bone; and although there are many indications of an artistic feeling which is pleased with its emancipation from precedent, they are probably to most eyes less sympathetic than those of a French jury, obscured by the determined revolt against all the canons of art, not to say of construction, hitherto received. Whether the "art nouveau" will ever develop into anything really worthy of the name of art, or whether it will simply pass away like the other eccentricities which, in all the arts, have had their vogue for a few years, only to vanish into oblivion, remains to be seen; but it is safe to say that it will never make much progress until it abandons the attitude of ill-bred defiance of what may or may not be the prejudices of people of taste which has become more marked of late. M. Chédanne, in the Palace Hotel, employed a style of design which, while strikingly original, was not impertinently so, and had a great charm, even to those who doubted the artistic value of the innovation. Since then, many of those who have followed his lead, instead of refining and enriching the beauties of his work, have selected the eccentricities, making them more eccentric still, until they have developed a set of stock patterns of their own, which have already lost their originality, and never had any other merit. It is the theory of some critics that every great architectural style has been, substantially, the invention of one man. If this is true, the "art nouveau" still awaits the man who is to give it real artistic dignity.

AN ingenious man in Minnesota, who is building for himself a handsome shoe-store, with a front of polished granite, has thought of a method of reimbursing himself for its cost, by cutting on the granite front the names of politicians, wholesale dealers, and other people who wish to see themselves advertised, charging, according to the newspapers, two dollars and a half for each name. There is probably some mistake about this latter point, as two dollars and a half would not pay for cutting the letters in granite; but at ten times the price the space would probably be readily taken up. Each name is allotted an area of seventy-two square inches, and as a store front twenty-five feet wide and fifty feet high would contain, after deducting the windows, about a thousand such spaces, a very tolerable sum might be realized, above the cost of cutting the inscriptions, by a person with a large acquaintance among business-men and politicians, to go toward paying the cost of a stone front in a conspicuous location.

THE AMERICAN VIGNOLA.[1]—IX.

PART I.—THE FIVE ORDERS.

PEDIMENTS.

THE Gable upon a Classical building is called a *Pediment* (136). It consists of a Triangular piece of wall called the *Tympanum*, which is in the same plane as the Frieze below; of a *Horizontal Cornice*, which divides the Tympanum from the Frieze; and of two pieces of inclined cornice which surmount the Tympanum. The inclined or *Raking Cornice* is like the cornice which crowns the wall on the sides of the building, but the Cymatium is a little wider. The Horizontal Cornice has no Cymatium, and generally terminates in a Fillet, called the *Split Fillet*, which divides at the angle where the two Cornices come together.

If the Cymatium is a Cavetto, the under side of the Fillet beneath it is bevelled, either on the rake or along the wall; if it is an Ovolo, the same thing happens to the Fillet above it. With the Cyma Reversa both occur, with the Cyma Recta, neither, the fillets having no soffit. This is one of the reasons for employing this moulding in this place (137).

When a Cyma Recta is used in the Cymatium it occurs in four different forms (138), viz: 1, the profile of the moulding along the wall; 2, the profile of the raking moulding; 3, the line of intersection of these two mouldings; this lies in a vertical plane, set at 45 degrees; 4, the line of intersection of the two raking mouldings at the top. 1, 2 and 4 have the same projection but different heights; 1 and 3 have the same height but not the same projection.

According to Vignola the obtuse angle at the top of the Pediment is included within an arc of 90 degrees. It accordingly gives a slope of $22\frac{1}{2}$ degrees. This is a good rule for most cases. But if a building is high and narrow, the slope needs to be steeper, and if it is low and wide, flatter. Inasmuch, however, as, for a building of a given width, the higher it is, the larger is the scale of the Order employed and of all the details of the Order, it follows that, for a given width of front, the larger the mouldings are, the steeper must be the slope.

Upon this is founded the following rule for the Slope of Pediments, devised by Stanislas L'Eveillé (139):

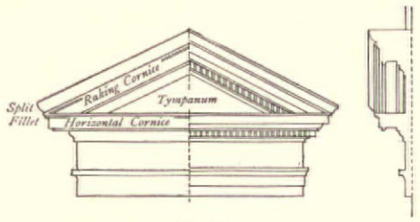

Fig. 136.

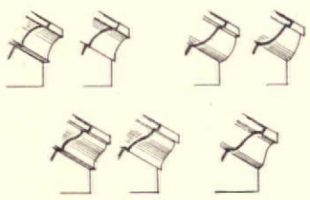

Fig. 137.

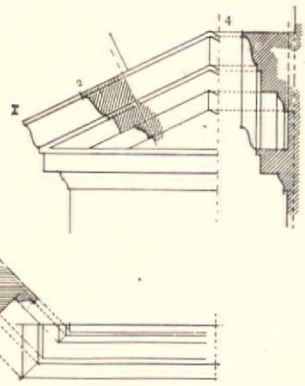

Fig. 138.

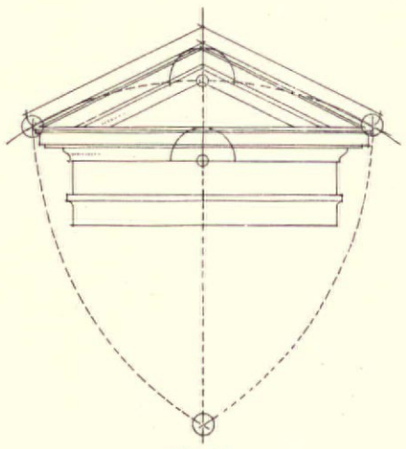

Fig. 139.

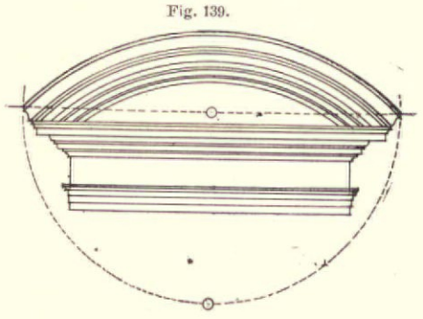

Fig. 140.

Taking the upper line of the Horizontal Cornice as one side, construct below it an equilateral triangle, and, taking the vertex of this triangle as a centre, and its side as a radius, describe an arc of 60 degrees. Taking, then, the summit of this arc as a centre, describe a circle, the radius of which is equal to the width of the horizontal cornice. Lines drawn from the extremities of the Corona tangent to this circle will give the upper line of the Raking Corona. It is obvious that the larger the cornice, relatively to the length of the front, the steeper will be the slope. It is also plain that this rule gives steeper Pediments for the Corinthian and Ionic Orders than for the Doric and Tuscan, and for the Roman Orders than for the Greek.

Circular, or *Curved*, *Pediments* have a sweep of 90 degrees (140), starting at an angle of 45 degrees.

When pediments are used merely for ornament the upper part is sometimes omitted, giving a *Broken Pediment* (141).

If the moulding that crowns the Corona is omitted the faces of the three Coronas are continuous (142).

PEDESTALS.

As has already been said, a short Pier is called a Post, and, if it supports something, a Pedestal, and the Pedestals that support Columns are generally made one-third the height of the Column. The Cap is one-ninth the height of the Pedestal, and generally consists of a Bed-mould and Corona. There is no Cymatium, a gutter being obviously out of place, but the Corona is crowned by a fillet and small Cyma Reversa. The Base, which is two-ninths of the height of the Pedestal, or, according to Vignola, only one-ninth, like the Cap, consists of a Plinth and Base-mouldings, among which a Cyma Recta is generally conspicuous, with a Torus below it.

The mouldings, in both Cap and Base, are fewer and consequently larger and simpler in the Tuscan and Doric Orders than in the Ionic and Corinthian, the Tuscan, according to Vignola, having no Corona, and the Corinthian a Necking and Astragal. The Cap projects less than its own height, in many examples, and the Plinth just as much as the Corona.

[1] Continued from No. 1390, page 53.

But Pedestals vary greatly both in their proportions and in their mouldings.

PARAPETS AND BALUSTRADES.

A wall low enough to lean upon is called a *Parapet*, and whether low or high is often strengthened by occasional Posts or Pedestals, sometimes of the same height, sometimes higher. In either case the wall or parapet has a Cap and Base which may or may not be like those of the Pedestals or Posts. A similar strip of wall, with the wall continued above the Cap, is called a *Continuous Pedestal*. This often occurs between the Pedestals that support Pilasters.

In antiquity, Parapets were often pierced by triangular penetrations, apparently in imitation of wooden fences (143). But in modern times the openings in Parapets are generally filled with a sort of colonnade of dwarfed columns called *Balusters*. These frequently occupy the whole space between one Post or Pedestal and the next, forming a *Balustrade* (144). If the distance is great, so that the Cap has to be made of several lengths of stone, a block called an *Uncut Baluster* is placed under the joint. Not more than a dozen Balusters should occur together without such interruption. Against the Pedestal is often set a *Half-Baluster*, or, which is better, half of an Uncut Baluster, to support the end of the Upper Rail (145).

The Cap and Base of the Pedestals, or of the Parapet or Continuous Pedestal, are called in a Balustrade the *Upper* and *Lower Rails*. The Baluster supports the Upper Rail as a Column supports an Entablature, and stands upon the Lower Rail as upon a Stylobate (146). It has its own Cap, the height of which, including the Astragal, is one-quarter the height of the Baluster, and which consists of a plain Abacus, Echinus and Fillet and Necking. These three members are of equal height, as in the Tuscan and Doric Capitals.

The Base of the Baluster is also one-quarter its total height and resembles the Attic Base. The Scotia, as in the Greek Attic Base, is generally made the principal member.

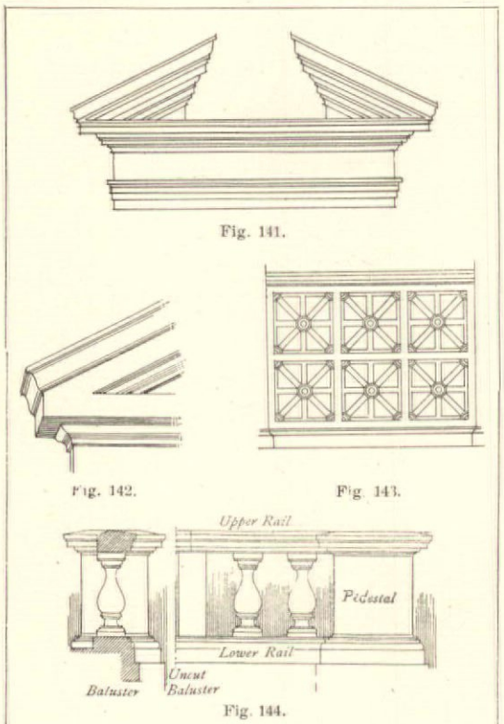

Fig. 141.

Fig. 142.

Fig. 143.

Fig. 144.

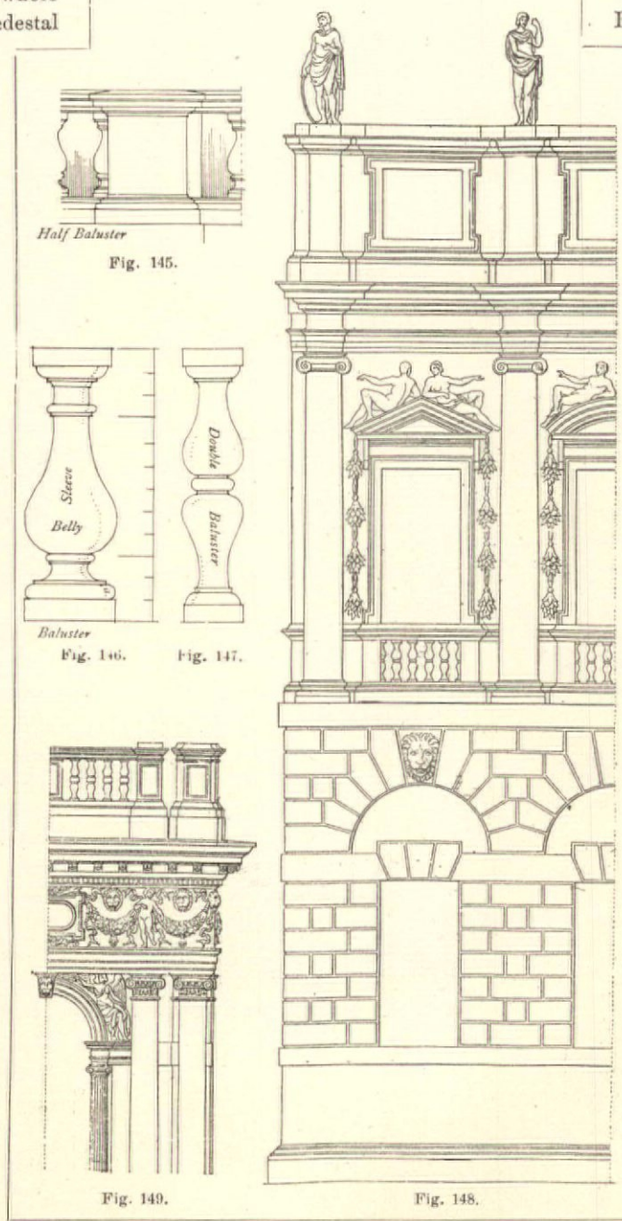

Fig. 145.

Fig. 146.

Fig. 147.

Fig. 149.

Fig. 148.

Between the Cap and Base is the Shaft, or *Sleeve*, which has the outline of a Quirked Cyma Reversa, the greatest diameter, or *Belly*, coming at one-fourth of its height, or one-third the height of the Baluster. Its width at this point is also one-third the height of the Baluster, as is also that of the Plinth of the Base, exactly, and the width of the Abacus, almost. The Necking is less than half as wide. The point of contrary-flexure in the Cyma Reversa is half way between Cap and Base, or between the Upper and Lower Rails. But these proportions are made somewhat lighter for use with the Ionic and Corinthian Orders.

The Rails are sometimes, in height, one-sixth and two-sixths of the space between them, like the Cap and Base of a Continuous Pedestal; but they are often made much heavier, even one-third and one-half.

Instead of the Cyma Reversa, a Beak-moulding is often used, and other variations are frequent. Of these the most important is the so-called *Double Baluster*, which consists of two small Balusters, set together base to base (147). Vignola also used a high block under the Plinth. Balusters are often made square in section, like piers, instead of round, like columns.

Balusters are set about half their height apart, on centres.

A Balustrade, like a Parapet, is intended to lean upon, and should not be more than about three or four feet high. While, therefore, Columns and Entablatures are proportioned to the size of the buildings in which they occur, varying in height from ten or twelve feet to fifty or sixty, Balustrades, like steps, are proportioned to the size of the human figure, and in large buildings are relatively much smaller than in small ones. They thus serve, as do steps, and as does the human figure when introduced into a drawing, to indicate the scale of a building.

But in very large buildings balustrades have sometimes been made of colossal dimensions, that on the top of the front of St. Peter's, for example, being about eight feet high.

ATTICS.

When a Parapet is placed on top of an Entablature it is called an *Attic*, that is to say, an "Athenian" story (148). Like Pedestals, Attics vary much in size and in architectural treatment. They are generally made about a quarter as high as the Order below, and should not be more than a third, and they should have a high Plinth, or even a double Plinth, so as not to be too much hidden by the projection of the Cornices on which they stand.

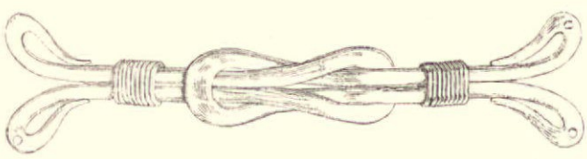
The place of an Attic is often taken by Balustrades (149), which also should have high Plinths, below the lower rail.

W. R. WARE.

THE ORNAMENTAL METALWORK OF P. L. BRINDEAU.

PAUL-LOUIS BRINDEAU practises an art that is simple, but elegant in line and happy in expression. A little hammer, a vice, chisels, a file, a few rods and leaves of thin copper, and from his hands spring appliqué work, escutcheons, pateras, hinges, door-handles, buckles, buttons, roses, of most marvellous effectiveness. It is a kind of jewelry for furniture, in base metal to be sure, without jewels or enamel, but it is nevertheless jewelry, with forms particularly fitted to their use: no part of it injures one or scratches; the hand meets with only friendly surfaces, the eye sees only graceful curves.

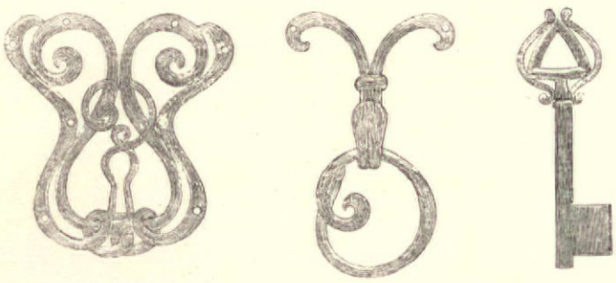
This easily vaporizable metalwork, which one would think would be torn apart like goldsmith's work at the least pull, is twisted upon itself in such a manner that the whole gives the resistance of a massive casting. It holds what it is meant to hold. With its ornamentation it transforms the most commonplace bit of furniture into a choice object, a pine cupboard into the most stylish of buffets. The patinas, from bronze to *vert de gris*, vary the tones of the work.



Sometimes bell-metal, yellow copper and red copper are allied in polychromatic interlacements, giving the most diverse of effects, and the most unexpected.

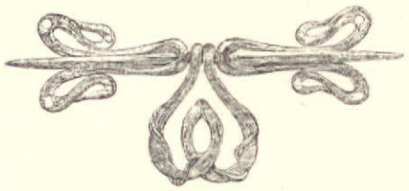
The exhibition of 1900 contained a series of this work of Brindeau's which was purchased by the Museé des Arts at Zurich. Since then, we have seen him at each Salon, this restless searcher, to whom the decoration of furniture, and of the house itself, owes more than one grace; and this year we see him again with a new blossom of his curious talent. All his work, as art, is perfectly firm. Its floral stylization unites in harmonious blossoming in an ensemble which is solid without heaviness.

Dampt, Sauvage, Marrou, Gallé, Prouvé, Robert, rivals of Brindeau's in work of analogous kinds, have carried the art of artistic ironwork to a degree of intellectuality that is impressive. It is, in truth, poetry in metal. But Brindeau has removed himself from a



style of work which is too arduous, which necessitated special workmen, and said to himself that the artist ought to produce his work by himself, with his own fingers, without any aid. Therefore, he translates his own thoughts, materializes his own forms. He has refused to be chief of a force, editing, as it were, in innumerable examples, work that he has designed on paper. When he places a copper wire in the jaws of his vice, he knows only one thing: the use to which he proposes the object shall be put. Then he starts, he bends, twists and turns the metal, flattening it here and there with a slight tap of his little hammer, all the time seeking for the right line, the best relief through a persevering study of possible combinations.

Better than any one he knows the plastic qualities of the material he employs, and only asks that which the material can grant him.



He attains extraordinary sumptuosity of line, multiplies them by symmetry, by repetitions and geometrical balancings. What he does with one wire, he repeats with another, with two others, and connects them. The thousand sinuosities which set out to distance one another twist upon one another and come back to the same end. They are not the issue of mere caprice; they are rational in their simplicity, and combine to the same end.

He mingles here and there leafwork with the wire, the plane surface with the relief, and ventures sometimes on fruits and flowers. His style is impressed with his own handiwork. It is rudimentary — a little brusque; but we like to have it so. His success is of good quality, and keeps on growing. Various museums of Europe are

beginning to dispute with one another for his product. The show-windows before which pilgrims of the renewed cult of form and decoration go into ecstacies are enriched with these bold and slender bits of metalwork. The amateurs, in whom intelligence is quickening every day, thanks to a criticism better comprehending its educational opportunity, present themselves daily at the door of the good artisan, dreaming of bearing away with them some "find" which shall lend pride to their hearthstone. Periodicals, reviews, journals, magazines photograph and spread broadcast his supple and enduring ideas.

His work is wrongfully reproached with being a little too meagre, too gracile, since really these tenuous lines are amalgamated and so intertwined as to offer a most satisfactory resistance. The eye is too much habituated to the heavy forms of cast metal, to round bosses, modelled after the motives of the statuaries. Here there is nothing of that sort. The docile wire follows the thought of the artist who thinks of nothing save of the use to which his work is to be put. — *L. Riotor in the Revue des Arts Decoratifs.*

ROMAN AND ROMANESQUE FRANCE.[1] — II.

ANTIPOLIS — ANTIBES.

AS early as 125 B. C. the Romans had a road to Spain via the Pyrenees — the Via Domitia; but the great Aurelian way which, passing by Genoa, fell into the older road at Arles was a subsequent work due to the Consul Aurelius Cotta. The Camin Aourelian, in Provençal, may still be traced along the shores of the Mediterranean, where it had the protection of the Roman fleet; then, after passing Ventimiglia (Albium Intemelium) and Mentone (Surnane) it crossed the Alps at Mont Agel (Alpe Summa), where we now find the ruins of Turbie, a gigantic fragment of the trophy celebrating the victories of Augustus over the barbarians. The road kept on the high ground after crossing the Alps (then the frontier between Italy and Gaul), and passing the Greek Colony of Nice (Nicæa) on the north, arrived at Cimiez (Cemenetium), where Roman remains prove the importance of the ancient town. The Var was then crossed, and Antibes (Antipolis), a little Greek port facing Nice, became one of the most important stations upon the Via Aurelia.

Whether the Provençal *Antiboul* was an offspring of Nice or of Marseilles, the learned have not yet determined, but it is certain, says M. Leuthéric, in his book upon the Riviera, that the Greek town dated back to the fourth or fifth century B. C.; for in 1866 the discovery of a stone with an inscription in archaic characters put the question beyond doubt. This stone is of a dark-green color, 22 inches long by 8 inches wide, and of the form of an egg, with the inscription written lengthwise in four lines. Literally translated it reads, "I am Terpon, servant of the august goddess Amphrodite; may Cypris recompense with her favors those who have placed me here." M. Leuthéric gives the views of various archæologists upon the

[1] Continued from No. 1376, page 47.

interpretation, which may be summed-up concisely as follows: The letters resemble those of archaic Ionian inscriptions mixed up with Greek ones about the end of the fifth century B. C. *Betuli*, or sacred stones, were worshipped by the early inhabitants of Chaldea, Phœnicia, Syria and Asia Minor. They were usually unhewn stones, black ones being especially adorable. Pausanias speaks of it as an old form of Greek worship, and many *betuli* which have survived to this period represent deities of the cycle of the primitive Aphrodite, a goddess reverenced in the ancient sanctuaries of the Island of Cyprus, "particularly in the temple of Golgos under the form of a conical stone," the analogue of the sacred stone of Antipolis. I had considerable difficulty in finding the stone. I was told it was near the church with many Roman slabs and *stelæ*, but it was not. Then it dawned upon me that it might be in the Hôtel de Ville, as a large Roman capital is placed in the hall of that building; so I asked the *concierge* if they had any sort of museum. "Yes," he answered, "but it is closed now." Thereupon another man came forward and said it was open, and "would I walk up." This we did, and after much fumbling at the door, which was locked, and a good deal of shutter unbarring, a very dusty collection of shells and prehistoric stones, and a few inscribed slabs became visible. The slabs were post-Roman, and nothing corresponded to the description of the stone in M. Leuthéric's book. However, after a considerable amount of conversation, the custodian lifted up a huge pebble, of exactly the form of those to be found on any sea-shore, and on it was the inscription as quoted. Whether the theory of the stone having been brought to its present shape by the action of the mountain torrent, and having been inscribed and made a sacred stone by some early settlers in Antipolis, be a fact or not must be left for archæologists to decide. But there surely cannot be two opinions upon the point that the authorities of the town might arrange their little collection better; and to keep it dusted might not, perhaps, be beyond their means.

The ancient remains at Antibes are few, by reason of the fact that each succession of occupants used up the stones placed by their forerunners, as was not uncommon all the world over. Rome placed its arsenal upon the ruins of the Greek city; the Middle Age builders used up Roman materials. Goths, Lombards and Saracens in succession destroyed in order to rebuild; and Vauban completed the work of destruction by surrounding the town with forts and battlements, built in a great degree with older fragments. These also have mostly been demolished — this time for the benefit of the inhabitants, and a new Antibes is rising up in the usual French manner. A large place is arranged with a central bandstand. Here are, for the present, some large buildings — a hotel, a military club and a few business premises. From this place, unfinished roads diverge at all the angles. Farther on, another place (at present unbuilt upon) is marked out with another set of diverging boulevards, finished only so far as the planting of young trees is concerned. Why cannot this sensible plan be adopted in the outskirts of our older towns instead of leaving all building-plans to the haphazard of private individuals, with the result that the new parts of a town soon get as congested as the older quarters.

Whether the church occupies the site of the Temple of Diana of Ephesus it is impossible to say. The two great towers which flank it are not of Roman times, but are composed partly of Roman stones, some bearing inscriptions. The theatre, which was in a ruinous condition, was razed to the ground in 1691; but a few remains of the Circus are said to be still visible in the cellars of some of the houses. The ground upon which the theatre stood was levelled and the only memorial of it still existing is an inscription "dedicated to the memory of a poor lad, perhaps a captive from the distant North, hired by some theatrical manager to appear on the stage at Antibes, where he died in the height of his success: 'Saltavit et placuit.'" (Leuthéric.) This slab has been built into the outside wall of the public library.

But modern Antibes is beautiful in many ways. It stands sentinel, as it were, to the cape, which is a mass of olive woods bounded by a wild, rocky coast. Upon the summit of the cape is a chapel dedicated to Notre Dame de Bon Espérance filled with ex votos given in gratitude by those who go down to the sea in ships and who have been saved from the dangers of the deep by the intercession of the Blessed Virgin — "Star of the Sea." The art displayed in some of the pictures does not equal the faith of the donors; but the effect of some models of ships hanging from wrought-iron brackets, accompanied by flags and lights, is picturesque in spite of the bad taste of the altars and of the building in general. Farther on is the modern "Star of the Sea," a first-class light-house which sends its brilliance many a mile to warn mariners of the dangers of the coast. In July the fishermen visit in procession the chapel, mounting the hill by the old paved, so-called Roman road, barefooted — thus the local guide-book as evidence of their religious sentiments; but a prettier "sentiment" is the tying on to the prows of their boats and to their cork floats of a piece of blessed palm.

Two or three portals, notably one in the main street, are worthy attention, and the fountain near the old place must not be passed by without a glance.

S. Beale.

The increased Use of Aluminium. — The remarkable increase in the use of aluminium during the past ten years is shown by the chart of mineral products of the United States, just issued by the Geological Survey at Washington. In 1891 the output was 259,885 pounds. In 1901 it was 7,150,000 pounds. — *Exchange.*

COUTURE AND DUTUIT.

FEW modern paintings excited more interest than "The Decadence of the Romans," by Thomas Couture. He was a morose artist, who lived in seclusion and brooded over his failures. He was out of harmony with his time, and it was really Imperial Paris which he satirized under the figures of ancient Romans. It is remarkable, however, that several able artists found their way to his studio. The despotism of the painter had the effect of making them indignant against his practice and the principles on which it was based. It is also curious that M. Dutuit, who has bequeathed to the Municipal Council of Paris a most valuable collection of paintings, and who was always a wealthy amateur, did not disdain serving the painter as a *rapin*, or pupil-servant. The incident is related by Couture in his "*Méthode et Entretien d'Atelier.*" We give a translation of the passage: —

"About 1842 I occupied a modest atelier in the Passage du Bois-de-Boulogne. The year before I exhibited a picture of a young Venetian after an orgy. It was noticed and purchased. Thereupon I abandoned competitions and sought the support of the public. From my début it was benevolent towards me. One day some one knocked timidly at my door and on bidding him enter I saw a singular person. His clothes were badly made, his shoes were large and heavy, and his trousers being too short allowed his blue stockings to be visible; in fact, he seemed to be clad in blue, and under his arm he carried one of those big umbrellas seen in the country and which was also of blue stuff. He hesitated about entering the atelier, his face was pale and troubled, and he appeared to be a mixture of a sacristan and a mendicant. He told me in a trembling voice that he would be happy to receive my instructions, and came to inquire whether I would take him for a disciple. I was ambitious, and in this case thought I would have more embarrassment than profit, so I brutally refused. He appeared very sorry for his intrusion and bent his head as if he were a culprit. I was moved by his extreme modesty and asked him would he care to be my *rapin*. That, he said, would be his greatest happiness, and I told him to make arrangements accordingly.

"He came back with an easel of whitewood, a small box, a couple of stools and a mattress. I instructed him about keeping the atelier in order. As a rule, the services are only rendered by young boys, and are never sought from a man, but the visitor was so humble he could be requested to do everything. Never was the atelier so well kept; the palettes were always clean and shining. He carefully watched me, and if I dropped a pencil picked it up and presented it to me with an old-fashioned bow. When the day was over he attended me to my lodging, and on leaving renewed his salutation. After some days he told me that I had said nothing about the fee he was to pay, and asked if seventy-five francs a month would be accepted. I explained to him that the best men were only paid twenty-five francs, and as he rendered me such good service I did not need any fees. He replied that in those ateliers there were a crowd of students who might never have the advantage of working with the master. As he insisted, I told him to give me the seventy-five francs, if the payment caused him no inconvenience, and to say no more on the subject. But he contrived to make a little packet of the money at the end of each month which I was sure to find in seeking for something else. Sometimes he wanted me to spend the evening with him and I refused. But once I accepted the invitation. We went to a good restaurant and were well served. I became alarmed about the expense for his sake, but he said he knew the owner, who was grateful for some little services he had done to him. We often went to auction-rooms, and I found he was skilful in the judging of old works. Once he said that a work by Hobbema, which we had admired, was sold for 37,000 francs. I replied they were happy who were able to acquire such masterpieces. That appeared to give him pleasure.

"He was not without intelligence and never neglected his service. It was impossible to tell his age — whether he was twenty-eight or sixty. He was bent like an old man, but one was interested in him and pitied him. We remained eighteen months together. A new *rapin* had arrived, and the old one had become my friend. One day he came to me in some excitement and announced that he was compelled to leave that evening, and would perhaps be absent for a couple of months. The next day a woman, who was a model, entered and told me that my student was a millionaire, and that he had gone in pursuit of a debtor who owed him 1,500,000 francs. I was surprised, for I supposed from what he said that he possessed not more than from four to five thousand francs of income. As he did not return, I imagined he had lost everything.

"Long afterwards in going to Havre I passed by Rouen, a city of which my friend had often spoken. I inquired after him, but was informed the only one of the name was the richest man in the country. However, I went to the house indicated as his residence and asked to see the master. I saw an old gentleman who bore some resemblance to my friend. I asked him if he had a son who was occupied with painting. In replying he told me who I was and said my visit was providential, for his son had only arrived the day before from Italy. When my ex-pupil appeared there was little change in his appearance. He conducted me to his room, which, he said, no stranger was allowed to visit. I was amazed at the number of marvellous masterpieces, and among them were several which I had looked at with him in auction-rooms. I questioned him if he was rich, He answered yes, and that he had not informed me of his position in order

that he might obtain sincere advice. Then he told me that if I wished he would bring me to Italy and that we should travel like princes.

"When he inquired about my affairs I told him that after toiling hard to obtain success in the Salon, the places assigned to my pictures were so bad that my efforts were lost. He asked if I had not influential acquaintances such as a dentist or a valet, and then he said we must change our rôles and that he would become my guide. The next day we travelled to Paris in a carriage. We traversed the dirty and narrow streets which then surrounded the Louvre, and went to a gallery where they were arranging the pictures for the Salon exhibition. He pointed out an assistant to me and bade me tell the man that my picture was numbered 334, and he would oblige me if it found a good place. I was to give him ten francs. The process was repeated with other assistants, and finally by his direction I gave twenty francs to the chief of the men. All the assistants seemed to be acquainted with my friend. A week afterwards the Salon was opened, my pictures were admirably hung, and I gained my first public success. Then he said to me, 'The farce is over, you are recognized by the public, and henceforth your pictures will have to occupy good positions. Take my advice, one never succeeds through great people; they are greedy and make their profit out of the simpletons who come to them. In preference seek the aid of humble people; by paying them you will be well served.' We then parted, and I have not seen my old pupil since."

Couture died several years before his friend. — *The Architect.*

THE LIGHTNING RESEARCH COMMITTEE.

THE Lightning Research Committee, organized by the R. I. B. A. and the Surveyors' Institution, in a recent communication to observers state that they are now in possession of a large number of first-hand reports on cases of damage to buildings from lightning-stroke. As regards the general character of the injuries to which *non*-protected buildings are subject from this cause, the Committee consider that the information already collected furnishes ample material for deliberation, and that it is unnecessary further to multiply observations as to *non*-protected buildings.

Data to hand, however, respecting "protected" buildings which have been struck are few, and generally meagre and unsatisfactory; and as the object of the Committee is to improve existing methods of protection they propose for the future to confine their investigations to buildings which have been struck in spite of being provided with lightning-conductors.

In order to determine the efficiency or otherwise of the conductor the Committee are of opinion that it is necessary to scrutinize minutely the actual conditions of the building affected. Observers are therefore requested to ascertain first whether the building struck is provided with a conductor, and if this be the case the structure should be carefully examined at once on the lines suggested below, and a photograph taken before any repairs, temporary or otherwise, are effected.[1]

Details additional to those indicated in the original form of questions are requisite to the more limited inquiry now contemplated. A general description should be given of the surroundings, especially of elevated buildings in the vicinity, and photographs should be taken in cases of importance; and if these elevated buildings are provided with lightning-conductors their positions and heights should be given.

The Committee suggest that the following points, drawn up for the Committee by Sir Oliver Lodge, should, *as far as possible*, be attended to by observers in making records of damage: —

1. Any signs or indications of where the flash appears to have first struck, and an account of the damage done.

2. A specification and drawing of the metalwork of the building, paying special attention to metal of every kind which comes anywhere in the neighborhood of the conductor, whether roof-guttering, lead-covering, rain-water spouts, sewer-ventilators, telephone-wires, bell-wires, gas-pipes, ornamental railings, etc., carefully ascertaining whether any of these were either purposely or accidentally connected with the lightning-conductor, and, if not, what their nearest distance was from it.

In the drawing all metals may be indicated in *red*, no matter of what kind they may be; the hypothetical path of the lightning, as appears to the observer most probable, may be sketched in *blue*, remembering that bifurcation of path is not unlikely. Places of damage may be indicated by a blue swelling or patch, the size of the patch giving a rough idea of the relative damage, and an arrow being employed, when necessary, to call attention to any small patches, liable to be overlooked. The patches may be numbered, and the nature of the damage at each place stated in the description. Any place where fire broke out is to be specially attended to.

3. The nature and condition of the conductor, especially with reference to its continuity, its earth, and its elevation; also how fixed, and, if carried horizontally, its length as compared with the vertical height of its terminal above the ground; also note whether it made any sharp curves or loops round projections of the building, or took an indirect course. Cases of damage where there have been more than one or several conductors are specially important.

In the case of church steeples, the wind-vane should receive special attention, and the mode in which its rod terminates in the steeple should be ascertained.

In the case of chimneys, any internal metal flue should be carefully specified. Likewise, any indication that the flash took the column of hot air, in preference to the conductor, should be recorded; also whether the conductor was bent or curved over the mouth of the chimney or not.

In any case of importance the earth of the conductor should be specially examined, being, if possible, dug down to for this purpose; and a complete specification of the nature of the earth, the nature of the soil, and of any metal ramifications as well as of moisture in its neighborhood, should be made.

Any signs that the discharge has entered the earth should be recorded; and if the conductor is at any point damaged or otherwise affected, this should be specified, and, when interesting, a sample of the damaged portion should be sent. If the conductor has recently been examined and tested, or otherwise reported on, the fact should be stated. — *Journal of the Royal Institute of British Architects.*

[1] The Committee wish it to be understood that they are prepared to defray actual out-of-pocket expenses, and also a moderate charge for the photographer's services, provided that complete details of the disaster be furnished within a few days after the occurrence, and that an account of the expenses incurred be sent in with the observer's report.

WHEN DO BUILDING OPERATIONS BEGIN?

MOLINE, ILL.

TO THE EDITORS OF THE AMERICAN ARCHITECT: —

Dear Sirs, — Can you say if this point has been legally determined: "What constitutes the first beginning of work on a building or wall?" This is to settle who is to build a certain party-wall. Is it letting of contracts, staking out of building, beginning to dig, or laying the foundations? An answer will be greatly appreciated by

Yours truly, OLOF Z. CERVIN.

[WE have an impression, from memory only, that the beginning of work on a building is, legally, the beginning of digging or other work on the actual site. This would not include the setting of the batter-boards, which are set outside the site, and are placed only as a preliminary to the actual building work. — EDS. AMERICAN ARCHITECT.]

NOTES AND CLIPPINGS

BIGGEST KANSAS COTTONWOOD. — In the Kansas Capitol square at Topeka stands a handsome cottonwood tree that has a history. Major T. J. Anderson, who is its historian, and when it was struggling for existence its friend and protector, says it first took root in 1869. It sprang from a seed which had found lodgment in the stoneyard where the contractors were dressing stone for the superstructure of the east wing of the Capitol. In the spring of 1870, when the men, fortified by a new legislative appropriation, returned to work after the winter's lay-off, the little sprout had taken firm root among the stone chips, and it was so green and vigorous in the waste that surrounded it that it attracted attention. It was in the way and the workmen wanted to pull it up, but Major Anderson interceded for it and a little pen was built around it. Henry Worrall said it was a "male" tree and would shed no "cotton," which added to the interest in it, and so it grew and flourished in the midst of the little desert of rocks. After many years the east wing was completed and the stoneyard was removed and blue grass took the place of the stone chips. In 1895 the tree was again in peril. It had grown into majestic beauty, and was the monarch of the Capitol square, but it was not located exactly to suit a landscape-gardener who had been imported from New York to "improve" the grounds, and he marked it for the axe. Again the friends of the tree came to the rescue and Governor Morrill ordered that it be saved. Men who frequent Topeka from other parts of the State agree that it is the largest cottonwood tree in Kansas, and, with the exception of an occasional elm, the most graceful. It is not so tall as some trees, being only about 85 feet, but its spread is 100 feet, forming a circumference of about 315 feet, and its foliage, when the sun is at the zenith, shades an area of 7,854 square feet. The circumference of its trunk is 12 feet. It is a favorite playground of children, and men and women seek its shelter from the summer sun. It came into existence almost at the beginning of the construction of the State-house, and lives to see the east wing begin to decay. — *Kansas City Times-Star.*

THE TABLET OF MENA. — Eadweard Muybridge, whose photographic investigation of animal locomotion attracted wide attention a number of years ago, has written the following letter to the London *Times*: "In the new volumes of the '*Encyclopædia Britannica*' is reproduced in the article 'Egyptology' a tablet of Mena dating from the first dynasty, or about 4700 B.C., and is the oldest written sentence yet discovered. In '*A History of Egypt*,' by W. M. Flinders Petrie, the author, referring to the Egyptian artists of the fourth dynasty, says: 'They did not make a work of art as such, but they rivalled nature as closely as possible.' Two figures — a bull and a deer — on the tablet of Mena afford a remarkable confirmation of the Professor's statement, in regard to the knowledge and expression of motion by the sculptor of this age. A bull striving to attain his utmost speed is represented in a phase of movement which after a lapse of sixty-six centuries is reproduced in a photo-engraving illustrating some consecutive phases in the stride of a horse, published in the '*Century Dictionary*' under the heading of 'Gallop,' and in the '*Standard Dictionary*' in its definition of 'Movement.' The phase employed by the Egyptian artist has been, until recent years, very rarely used in art; the nearest approach to it that I can at this moment recall is in a fresco painting on the walls of the Campo Santo at Pisa, supposed to have been executed by Pisano. It, like the Mena tablet, illustrates a phase of the transverse gallop — a system of motion adopted by the horse, the ox, and the greater number of animals, whether single-toed, cloven, or soft-footed, when they exert their utmost power to attain their highest speed. In the lowest line of figures on the tablet is a deer, evidently jumping over an obstacle. The animal is represented with all its legs flexed, in pairs, under its body. A precisely similar phase may be found in a series in the library of the British Museum, demonstrating a jump which sometimes takes place in the rotatory gallop of the deer, which system of motion is always used by the deer and also by the dog, when from caprice or necessity they endeavor to make rapid progress. This distinctive method of galloping was unknown, and, indeed, unsuspected, by us moderns, until revealed by photographic investigation of animal locomotion; but it was apparently well known to the early artists of Egypt."

SIMILARITY BETWEEN STANDARD PATTERNS AND GEOLOGICAL FORMATIONS. — The increased use of natural objects in what, for lack of a better term, is called industrial art, is largely due to some lectures delivered not long ago by university graduates before the schools of art design in this city, says the New York *Evening Post.* Prior to that time the work had been either along conventional lines or else entirely original, frequently painfully original. The lecturers called attention to the remarkable beauty and utility of many of the fossils, both plant and animal. What made the matter more interesting was the resemblance, they pointed out, between many standard patterns in textiles and designs in metalwork and commonplace features in the earth strata. The black-and-white-dotted calico might have been printed from the rain-marks found in the old red sandstone in the Connecticut River. The dot-and-line pattern so common in men's neckties is almost a copy of the graptolites found in the State of New York. The *arabesquerie* of Moorish interiors is a fair imitation of the bark of the *lepidodendra*, and many of the spirals used on wall-papers and carpets find a prototype in either geologic cycads or some species still living in Australia. These lectures have borne much more fruit than is commonly known. Hundreds of original designs made in the past six years are either borrowed or modified from these sketches by Mother Nature written upon the rocks. A woman who gets up fancy silk patterns for neckwear acted upon the advice in the lecture and devised some 15 or 20 arrangements of color based upon the Franklinite ores in New Jersey. These consist of mixtures of different-colored crystals: black, scarlet, gold, white, brown, green and bluish, and are always restful and at the same time impressive. In these Nature has harmonized the combination of bright colors just exactly as the Tartars do in Russian Tartary. Every one of the Franklinite designs made a hit, and has been seen on Broadway in tens of thousands of cravats and scarfs.

SACRILEGE AT STRATFORD-ON-AVON. — Can nothing be done, asks a correspondent of the *Times*, to stop the sad desecration that is now going on at Stratford-on-Avon under the guise of doing honor to Shakespeare? His house is carefully preserved and decently shown; but the desecration of the fine church is almost a national scandal. I found the church-doors open and guarded by men who demanded a fixed fee for admission — a fee which is absolutely illegal in any English parish-church. The visitors, having thus had a practical lesson that they were admitted to a show, treated the place as a showroom and nothing more — talking, laughing, kodaking, and sandwich-eating — no man forbidding them. Photographs and other memorials are openly sold inside the church; the sacred building is turned into a house of merchandise, and the whole show is run on the vulgar lines of a catchpenny and money-making exhibition. I have no doubt that the vicar and churchwardens lay the flattering unction to their souls that the money so earned is well spent, and so *bene olet;* but most English Churchmen would say *non redolet, sed olet.* If it is spent in the so-called restoration, they cannot be congratulated on the result. Restoration at Stratford means the sweeping away of everything that could have had any connection with Shakespeare: filling the fine windows with poor glass — some quite hideous — and erecting a black-and-white pulpit which is of good workmanship, but is a marvel of expensive ugliness. If the vicar and churchwardens really cannot run the show with more decency, let them confess their weakness and give it up. — *The Building News.*

THE STABILITY OF ST. PAUL'S. — Although alarmist statements made at intervals concerning the safety of the Metropolitan Cathedral must be considerably discounted, it is undoubtedly the fact that engineering operations of a subterranean character are responsible for injury to the foundations, and we are glad to think that no future work of the kind is likely to be permitted in its vicinity without the most careful scrutiny. So far as the present condition of St. Paul's is concerned, it appears from the recent report of two well-known engineers appointed to investigate the matter that the fears entertained by the authorities were by no means unreasonable. The foundations are found to have been impaired by undermining in the neighborhood of the building, and remedial measures are considered to be absolutely necessary. Probably, the large sewer in Carter Lane is the most serious menace to the structure, but the other engineering-works which we have mentioned in previous "Notes" are also responsible for alteration of the original conditions of the subsoil. One unfortunate circumstance is that, while costly repairs are continually required to national monuments, the general public appears to be happily oblivious of the fact that restorative work of the kind means the expenditure of large sums of money that are not always available. — *The Builder.*

A HARD CEMENT. — Frequently it is found that the ordinary plaster-of-Paris or calcium-sulphate cements are not tough enough for the purposes for which they are intended, and the operator is put to considerable trouble to find a suitable substitute. Our German contemporary, *Die Fœber und Zeugdrucker Zeitung*, in a recent article on the subject, states that a mass resembling rich clay, and which will set in about an hour, becoming sufficiently hard to bore, cut or file, may be obtained by mixing six parts of gypsum (sulphate-of-lime) with one part of freshly washed lime. To this, 8 per cent finely powdered marshmallow-root must be added, and the whole mixed with a concentrated solution of sulphate-of-magnesia (commonly known as Epsom-salts) in sufficient quantity to form a stiff paste. In place of the marshmallow-root, dextrin, gum or glue may be substituted, or shellac if the objects to be joined are to be subjected to high temperatures. — *Stone Trades' Journal.*

"When do Building Operations begin?" 95

NOTES AND CLIPPINGS. 95

THE *Engineering News* makes some very sensible comments on the tests of fireproof wood recently made at the Insurance Engineering Experiment Station in Boston. These tests showed that the material so named is very far from being fireproof, and that, at best, it simply ignites more slowly, and goes out sooner, when the source of heat is removed, than untreated wood. The officials of the Experiment Station do not think that these qualities give the fireproof material much superiority over ordinary wood, and it is true that, if a conflagration should start in a building, little difference would probably be observed in behavior between treated and untreated wood; but, as the *Engineering News* well says, a material which does not catch fire easily may be of great use in construction, even though incapable of sustaining intense heat. Mr. Atkinson, in commenting on the report of the Experiment Station, describes the best fireproof door as one of wood, covered with tin. He could not seriously expect the owner of a hotel or office building, dependent for tenants in a great degree upon the appearance of his rooms, to equip it with doors covered with sheets of tin; and the report would probably have met with more favor among those for whose benefit it was intended if it had pointed out that it is not at all necessary to choose between inflammable doors, or wainscoting, and the tin-covered woodwork familiar in boiler-rooms and coal-bins, American enterprise having for some years furnished doors and panelling of wood, completely covered with metal, as neatly and richly moulded as solid woodwork; while several hundred American architects stand ready, whenever called upon, to develop this construction into unheard-of beauties. In fact, the treatment of metal-covered wood fittings of this sort, in bronze or brass, modelled, chased or otherwise ornamented, offers a wide field of beautiful effects, and there is no question that woodwork so protected is, or can be made, quite as fireproof as the ordinary combination of boards and roofing-tin. It would be more expensive, but that is not a very serious matter in costly buildings, and it might be possible to rub a pine door over with black-lead, and electroplate it with copper or brass in a continuous covering, at a comparatively moderate cost.

ONE of the most energetic and most heartily berated men whose activity occupied the attention of the last generation was Alexander R. Shepherd, formerly Governor of the District of Columbia. Soon after the Civil War, Shepherd, then a young plumber in Washington, became conspicuous as a politician, and gradually made his way to the proud title of "Boss." At that time the city of Washington was little more than a filthy swamp, with a few magnificent public buildings scattered about in it. There is a story that some people, during the Civil War, excavating in Pennsylvania Avenue, came across a regiment of soldiers, which had attempted to march up the Avenue, but had been engulfed in the mud. Assistance was summoned, and the soldiers were dug out, but, on being liberated, they besought the workmen to continue their labors, as there was another regiment underneath. Even supposing this tale to be exaggerated, there was plenty of truth in the accounts of the filth and malaria of Washington which were carried North by returning soldiers and officers, and led to a serious movement to have the capital of the nation transferred to some more civilized city. Just at this time President Grant, who loved energy, had occasion to appoint a new Governor of the District of Columbia, and Shepherd, who had been for two years Vice-President of the Board of Public Works of the District, and had introduced various improvements, seemed to him a suitable man for the post. Notwithstanding the opposition of the citizens, he was appointed, and entered at once upon a career of what seemed to the taxpayers wild extravagance. In a little over two years he spent forty million dollars in pavements, sewers, public buildings and other improvements, and saddled upon what was then a town of very small resources a debt of twenty-seven millions. At the end of his term of office he retired under a storm of execrations from the citizens of Washington and from the newspapers of the country, which accused him not only of mad extravagance, but of corruption; few, if any, having the foresight to comprehend the great work which he had accomplished for his native city. The charges of corruption were not sustained, and probably had no foundation. The Governor, on retiring from office, went back quietly to his plumbing business, in which, after some vicissitudes, he saved up a little capital, and went to Mexico, in the interest of some of his friends, who had confidence in his judgment. Joining their resources with his own, he bought the old Batopilas silver mines, and established himself permanently as manager. Under his direction the enterprise prospered, enriching both his friends and himself. Meanwhile, Washington, which had been converted by his energy, and against bitter opposition, from a dull, straggling Southern town into the promise, at least, of a great and splendid city, has begun to fulfil the anticipations which he alone seems to have been capable, thirty years ago, of forming for it, and it may be hoped that among the future attractions of what seems destined to be the most beautiful city in the world, some memorial to the much-maligned Governor Shepherd may not be forgotten.

THE practice of throwing city sewage into a fresh-water lake, and pumping drinking-water out of the same lake, a few miles beyond the sewer outlet, is again producing its legitimate result in Chicago. Although the Chicago River no longer pours its reeking floods into Lake Michigan, but sends them, instead, toward St. Louis, a portion of the sewage of Chicago still finds its way to the Lake, and there, instead of being immediately purified and rendered harmless, is so ill-advised as to creep into the water crib, to be pumped, mixed with drinking-water, into the houses of the city. A week or two ago, there were three hundred and twenty-seven typhoid patients in the County Hospital alone; and the use of the city water has proved so dangerous that the drinking fountains in the schoolhouses have been shut off. Whether anything can be done to remedy the trouble remains to be seen. We may confess that our sympathies are not greatly excited by the failure of schemes for throwing the sewage of great cities into lakes or rivers, to poison people, when it might, instead, be converted, by irrigation, into flour, and beef, and potatoes, and wool to feed and clothe them; but every one must deplore the immediate results of the mistake. Fortunately, Chicago is rich, and enterprising, and intelligent, and it will not look on very long at the decimation of its population by a bad water-supply without devising some remedy.

A CURIOUS distemper has broken out among the "industrial combinations" which, as we are so frequently told, have permanently revolutionized methods of production. A day or two ago, the Quincy Granite Quarries Corporation, formed by the combination of the principal quarrying firms at

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

Quincy, and professing to be the largest producer of granite in the world, defaulted the interest on its bonds. The newspapers explained this circumstance by saying that it was part of a plan for "securing new working capital"; that the business was profitable, but additional working capital was needed, and that, to obtain this, a reorganization was to be effected, under which a large additional issue of bonds was to be made, bearing high interest, and rendered attractive to purchasers by a bonus of new preferred and common stock. Presumably, in order to effect this reorganization, it would be necessary to foreclose the existing bonds, and it might be inferred that the default of interest was made purposely to give occasion for this. Meanwhile, the people who hold common and preferred stock in the present company, which will be cut off by foreclosure, are likely to view the proceedings with a certain interest. Undoubtedly, they will be given the right to take new stock, upon certain terms; but the suggestion naturally presents itself that the holders of the defaulted bonds are legally entitled, if they choose, to sell at auction, under foreclosure, all the assets of the corporation, to satisfy their claim, without troubling themselves about the interests of the preferred and common stockholders; and that, if they have concluded, at present, to give the stockholders a chance of saving some of their property, for the sake of inducing them to subscribe to the increased issue of bonds, there seems to be no reason why the same process should not be repeated wherever new "working capital" is needed.

IT is a little singular that a corporation composed of a number of prosperous concerns should, in a time of general activity, and high prices, need more "working capital," but the same condition of things, it appears, afflicts also the American Bicycle Company, a combination, as we need hardly say, of the principal bicycle manufacturers of the United States, and, in order to obtain the funds which it needs to "carry on" its prosperous business, this corporation has also made default upon its bonded indebtedness, and is, we are told, to be reorganized on the basis of a still larger indebtedness, and still further sacrifice of the value of the stock. Probably, in both these cases, the stockholders are also, in most cases, bondholders, and the reorganization is, practically, a rearrangement of the financial plan of the corporation, perhaps intended only to give the bondholders a larger interest on their property; but it must be confessed that "deals" of this kind, whether in the interest of "insiders" or not, are not likely to attract the public toward investment in either the stock or the bonds of such corporations. Apart from this, however, the fact that industrial combinations, even when prosperous, seem to feel a chronic need of money is of importance. It is said by some manufacturers that the claim put forward in advocacy of industrial combination, that economy and efficiency are promoted by it, is not well founded; and that manufacturing operations are never so economically and efficiently conducted as when they are controlled by one man, thoroughly familiar with all the details of the business. It seems as if there might be reason in this, but if the difference in economy is so great that a combination of establishments, which had each been carried on profitably by one man, is likely to find itself, within a few years after competition has been eliminated by consolidation, unable, even in times of general prosperity, to pay the interest on its mortgage bonds, the student of industrial conditions, as well as the humble investor of his own or other people's savings, would be glad to know more about the matter.

AS we expected, Professor Boni has ascertained that the foundations of the fallen Campanile at Venice are perfectly sound, and that the superstructure can be rebuilt upon them without danger. The cost of rebuilding is now estimated at six hundred thousand dollars, or half the sum which, as the newspapers reported, the Venetian Government thought would be necessary. We are inclined to think that the last estimate is at least twice too high; and, as three hundred thousand dollars are said to have been already subscribed, it is not surprising to hear that the work is to be begun without delay.

A NEW agency in the industrial world has been established in the formation of two companies, one in Germany, and the other in Austria, for insuring manufacturers against loss through strikes. The Austrian company, which seems to have the most radical and comprehensive programme, is to be a mutual one, composed of two hundred and fifty manufacturers, having an annual pay-roll of not less than five million dollars. In case of an "unjustifiable strike" in the establishment of any member of the company, one-half the amount of the regular pay-roll of the establishment will be paid to its owners, out of the reserve fund of the company, so long as the strike continues, if it does not last more than three months; but indemnity will not be paid for more than three months on account of any one strike, nor for more than six months in any one year; the obvious intention of this regulation being to stimulate policy-holders to adjust their labor troubles quickly, and to maintain an attitude toward their employés sufficiently conciliatory to avoid frequent controversies. The indemnity, of half the regular pay-roll, is not intended to reimburse the policy-holder for loss of profits through strikes, but simply to make good to him the outlay necessary to keep his establishment in good order and repair during the cessation of operations. As to what constitutes an "unjustifiable strike," entitling the sufferer from it to indemnity, a few rules are laid down, but the application of them is placed in the hands of an executive committee. A strike of workmen to enforce a demand for the dismissal or employment of any person is classified as being always unjustifiable, and as giving a valid claim to indemnity. In other cases, where "demands have been made which the condition of the business does not justify," or which "threaten the authority of the management," the executive committee makes an examination on the ground, the policy-holder being bound to give full and truthful answers to all questions, and is empowered to endeavor to bring about an understanding between the parties. If it fails, its report decides finally whether the case warrants the payment of indemnity. It is hardly necessary to say that the interest of the company, as well as of its policy-holders collectively, lies in the avoidance or speedy settlement of strikes, so that it is likely to be an important agency in the direction of industrial peace; while its rule, that it will support all its members against coercion by strikes in the matter of employing or dismissing workmen, is likely to take from the hands of the agitators the terrible weapon by which they have for so many years extorted money from their victims, and driven to despair those who ventured to question their authority.

THE American Consul at Patras, Greece, calls the attention of American architects to an international competition for designs for a large church in that city. The church is to accommodate five thousand people, and is not to cost more than two hundred and fifty thousand dollars. Naturally, it is desired that the building should be in the Byzantine style, and it must be designed with a view to resisting earthquakes, which are very common in that part of Greece. The contest is a double one. In the first competition, which closes February 13, 1903, plans, elevations and a perspective view are required, at a small scale, and a certain number of designs will be selected, the authors of which will be invited to submit additional drawings. Five months will be allowed for the preparation of these additional drawings, and, at the end of that time, the competing designs will be submitted to some academy of fine-arts, which will make the final award. In accordance with the award, three prizes will be distributed, varying from four hundred to two thousand dollars.

THE people who have crossed the Gemmi Pass, where an overhanging cliff, fourteen hundred feet high, separates the fair-haired, blue-eyed, German-speaking Protestants of Canton Bern from the dark-haired, French-speaking Catholics of Canton Valais, will be interested to learn that steps are to be immediately taken to construct a tunnel under this pass, from Frutigen, on the north, which is already in railway communication with the Swiss railway system, to Brieg, a station on the Paris, Lyons and Mediterranean Railway, and the terminus of the Simplon tunnel. It is evident that the Swiss, and probably, the Germans also, view with misgivings the progress of the Simplon tunnel, which will throw a vast traffic from Genoa and the rest of Italy over the French lines, and have determined to intercept, if possible, a portion of it, by a tunnel which will connect the Simplon directly with Bern, Basel and the Rhine valley. By a great majority, the people of Canton Bern recently voted to subscribe for one-fourth of the stock of the tunnel railway; and the manufacturers of the region served by it will undoubtedly find the investment a profitable one.

NOTES ON IRON AND STEEL CONSTRUCTION.[1] — X.

STEEL-BEAM grillage is the form of foundation-construction shown in Figure 68, and this type of foundation is principally resorted to where the loads to be supported are heavy and the soil is exceedingly plastic. Its use is especially recommended where a thin and compact stratum overlies another of a more yielding nature, and where, in consequence, the allowable height of the foundation is limited, for, if possible, the requisite area for the foundation must be obtained without penetrating the firm strata, and without encroaching too much upon it. The steel-beam grillage type of foundation is especially adapted for tall buildings, and particularly in those buildings in which the entire load is carried on isolated footings or piers — that is, where there is no continuous foundation-wall.

The advantage of this type of footing in such instances exists in the fact that they can be nicely proportioned, so that uniform settlement is ensured; besides, steel-beam grillage affords a foundation which has a minimum height — that is, the distance between the top of the column base and the bottom of the footing is less than in any other type of footing when correctly proportioned. This type of footing also possesses the advantage that it may be readily and rapidly constructed, and at a reasonable cost.

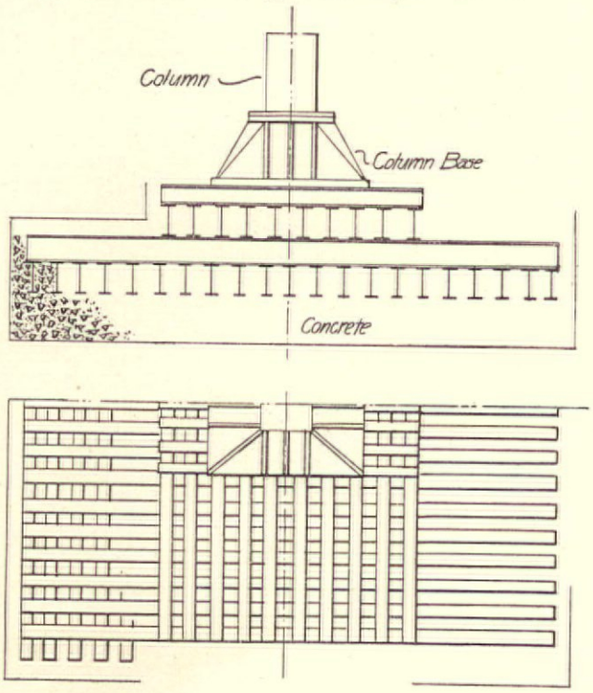

Fig. 68.

Steel-beam grillage footings usually consist of two or more layers of steel I-beams or rails. In constructing this type of foundation a bed of concrete not less than 12 inches thick, composed of 1 part Portland-cement, 2 of sand and 5 of broken stone is first laid; upon this the steel I-beams in the first tier are placed side by side, there being a sufficient number of them to distribute the load over the desired area. These beams are entirely bedded in the concrete by filling between and thoroughly ramming. The second tier of beams, supporting the cast-iron base, is laid across the first layer, reaching to the extreme outer edge; the space between these beams is likewise filled with concrete. Separators must be provided between the I-beams, and the distance between the separators should not exceed 5 feet. The tie-bolts holding the separators in place should pass through the entire tier of beams. The I-beams in each tier should never be spaced closer than 3 inches at the flanges, as a less space would interfere with the ramming of the concrete, neither should the I-beams be spaced at a greater distance apart than 18 inches between centres.

In designing this type of footing the steel beams on the sides and at the ends should be entirely covered with concrete so that they are protected from corrosion. It has been a much disputed question in the minds of engineers whether iron and steel imbedded in concrete possesses durability. From examination of past work it has been thoroughly and conclusively proved that steel or iron when thoroughly imbedded in cement-mortar or in a complete concrete will last indefinitely. Great care should be exercised to prevent initial corrosion from the moisture contained in the concrete before setting; this may be accomplished by thoroughly painting the beams with several coats of a good preservative paint, preferably a mixture of red

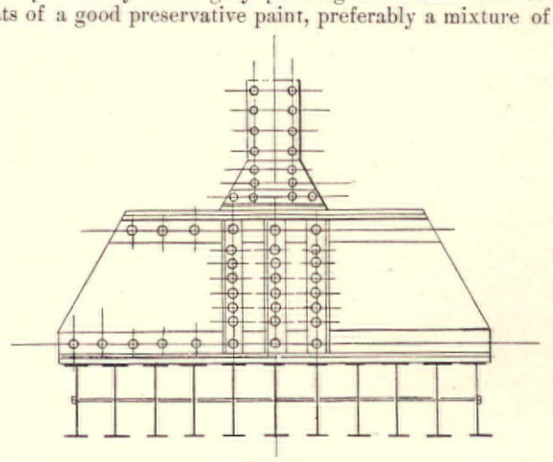

Fig. 69.

and white lead and linseed-oil. Cinder-concrete is not recommended for this type of foundation-construction, for the cinders contain chemical elements which, when united with water, are apt to promote the destruction of the steel. Should the load upon the foundation be so great as to require more beams in the second tier than can be conveniently spanned by the cast-iron base, a third tier of beams may be introduced, or a box-girder as shown in Figure 69 may be used instead of the beams. It is interesting in connection with this type of foundation to note the stipulations of the New York Building Law, which is as follows: —

"Grillage-beams of wrought-iron or steel resting on a proper concrete bed may be used. Such beams must be provided with separators and bolts enclosed and filled solid between with concrete, and of such sizes and so arranged as to transmit with safety the superimposed loads.

"Where metal is incorporated in, or forms part of, a foundation it shall be thoroughly protected from rust by paint, asphaltum, concrete, or by such materials and in such a manner as may be approved by the Commissioner of Buildings.

"When footings of iron or steel for columns are placed below the water-level they shall be similarly coated or enclosed in concrete for preservation against rust."

The principal element in the design of foundations of this kind is the determination of the size of the steel beams. Where the foundation is constructed as shown in the diagrammatic drawing (Fig. 70), there have been two methods proposed by which the size of the beams may be determined. Some engineers figure the bending-moment upon the lower tier of beams to the point c, and in calculating this moment they determine the load per lineal foot sustained by all of the beams in the tier, and multiply the value thus obtained by the *projecting* length of the steel beams, obtaining the bending-moment by multiplying

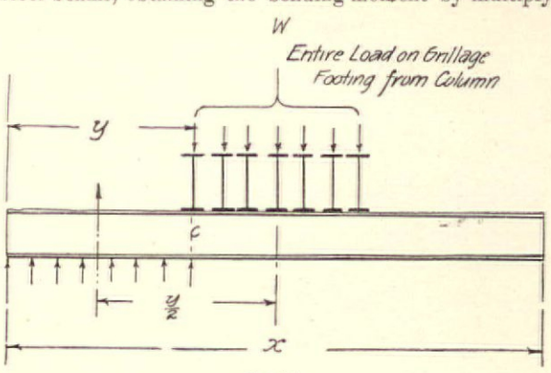

Fig. 70.

the product by one-half the projection of the steel beams composing the tier in question. For instance, let W equal the entire load coming upon the grillage-footing from the column, and let the length of the beams in the lower tier equal x. Then the entire pressure upon the soil will equal $\frac{W}{x}$. The upward force

[1] Continued from No. 1386, page 21.

acting upon the projecting portion of the beams in the lower tier, provided the projection is equal to y, will equal $\frac{Wy}{x}$, and the bending-moment about the point c will, consequently, be expressed by the formula $M = \frac{Wy^2}{2x}$.

Example. — Assume that in Figure 71 the weight W equals 200,000 pounds, and that the projection of the grillage, or y, is

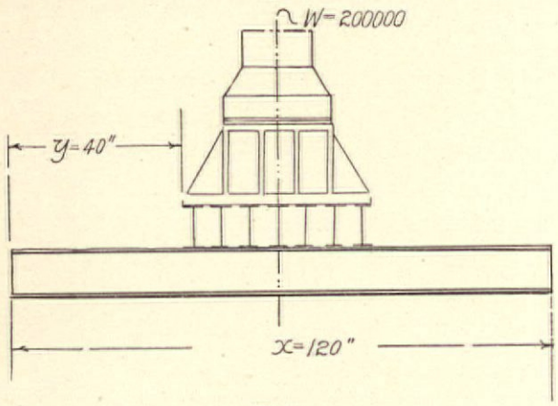

Fig. 71.

equal to 40 inches, while the total length of the beams in the lower tier is equal to 120 inches. By applying the formula $M = \frac{Wy^2}{2x}$ the value of M, upon substitution, is found to equal $\frac{200{,}000 \times 40 \times 40}{2 \times 120}$, or, 1,333,333 inch-pounds. Provided there were 10 beams in the bottom tier, the resisting moment required in each will equal 1,333,333 ÷ 10, or 133,333. If a unit fibre-stress of 18,000 pounds is considered allowable, the section modulus required for each beam will equal 133,333 ÷ 18,000, or 7.4, and 7-inch beams, weighing 15 pounds, would probably be used.

The assumption upon which this formula just demonstrated has been based is that the greatest bending-moment occurs at the point c; this is theoretically incorrect, for the greatest bending-moment on the bottom tier of beams occurs at the centre, or at the point c in Figure 72. Though the advocates of the formula just given claim that the results are amply safe, because the concrete between and around the beams reënforces them and cannot but increase their strength materially, the more conservative practice prefers to consider the greatest theoretical bending-moment, that is, the moment at the centre of the beams in the lower tier. This formula is readily solved by the theory of moments, and their application to the strength of beams, which was treated at length in a previous article.

Referring to Figure 72 let the weight upon the column, or the load transmitted by the upper tier of beams, equal W, and

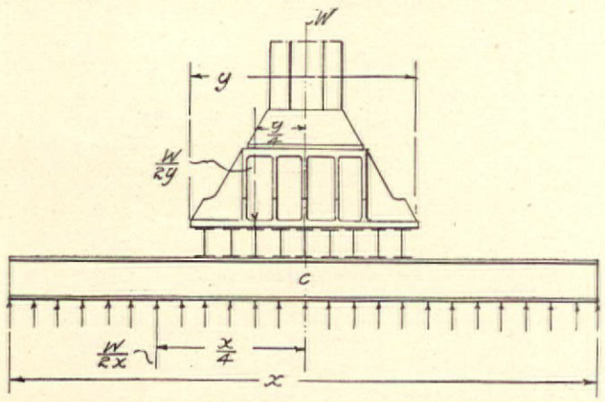

Fig. 72.

let the length of the lower tier of beams, as before, equal x, while the width of the upper tier of beams is equal to y; the upward pressure per inch of length upon the lower tier of beams in the grillage will then equal, as before, $\frac{W}{x}$, and as these forces can be considered as forming a uniformly distributed load, the length of lever-arm of that portion upon one-half of the tier is equal to the distance from the centre-of-gravity of the half-load to the point c, or $\frac{x}{4}$, so that the upward moment of the pressure from the soil upon one-half of the length of the beams in the lower tier of the grillage is equal to $\frac{W}{2x} \times \frac{x}{4}$, or, $\frac{Wx}{8}$; there is opposed to this upward moment a downward moment about the point c equal to $\frac{W}{2y} \times \frac{y}{4}$, or $\frac{Wy}{8}$, so that the algebraic sum of the moments about the point c is equal to $\frac{Wx}{8} - \frac{Wy}{8}$, or $W\frac{(x-y)}{8}$, or, as it is usually expressed, $\frac{1}{8} W (x-y)$. This formula being so commonly used, may be expressed in the following: —

Rule. — The bending-moment upon the beams in the bottom tier of a grillage-footing is found by multiplying one-eighth of the load from the column by the difference between the length of the lower tier and the width of the upper.

Example. — Assume the conditions proposed in the previous problem, in which the load upon the column was 200,000 pounds, the width of the upper tier 40 inches and the length of the beams in the lower tier 120 inches. By substitution in the formula $M = \frac{1}{8} W (x-y)$, the value of M is found to equal $\frac{200{,}000}{8} (120 - 40)$, or 2,000,000 inch-pounds. This, as will be noted from the result previously obtained by the first formula, is considerably greater, which demonstrates conclusively that, theoretically, the greatest bending-moment is at the centre

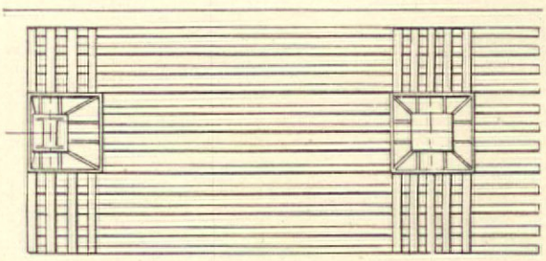

Fig. 73.

of the under tier of beams in the grillage, and not at the edge of the outer tier. In this instance, since the bending-moment is 2,000,000 inch-pounds, and there are ten beams in the tier, the bending-moment upon each beam would equal 200,000 pounds, and if a safe-unit fibre-stress of 18,000 pounds is assumed, the section modulus required for each beam will equal 200,000 ÷ 18,000, or, approximately, 12, and in consequence, there would be required for the lower tier of this footing ten 8-inch I-beams, weighing 18 pounds per foot.

In the design of steel-beam grillage it is often found necessary to support two columns upon one continuous tier of beams. Such construction is usually required on account of the proximity of the columns, and because it is impossible to secure sufficient area by means of a single grillage-footing under the separate columns, and while this construction should never, if possible to avoid, be resorted to, its use oftentimes becomes imperative. The principal difficulty in the design of such a footing as described and shown in Figure 73 exists in the fact that if one of the columns is more heavily loaded than the other, the footing at the end supporting the heaviest load will tend to settle more than at the other. This unequal settlement or tilting is sure to occur when the soil is of a plastic nature, when the variation between the loads of the column is great, and when the footing is made the same width throughout its length. To obviate this difficulty it would seem reasonable to design the footing in the form of a trapezoid, the narrow end of the trapezoid being adjacent to the column supporting the heaviest load. In other words, the centre-of-gravity of the column loads should coincide with the centre-of-gravity of the resultant reaction from the pressure of the soil. Before designing such a footing it is consequently desirable to determine the centre-of-gravity of the loads, assuming that there is a variation between them; in order to determine the distance from one end of the bottom tier of steel beams to the centre-of-gravity of the loads, the following formula can be applied: —

$$D = \frac{(W_1 \times y_1) + (W_2 \times y_2)}{W_1 + W_2}$$

in which D equals the distance from one end of the bottom tier of steel beams to the centre-of-gravity of the loads, W_1 equals the load upon the first column, and W_2 the load upon the second

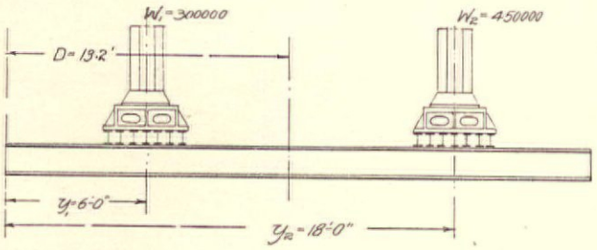

Fig. 74.

column, while y_1 and y_2 equal, respectively, the distances of W and W_2 from the same end of the grillage as D is to be measured. This formula is the same as employed for the determination of the neutral axis, or a line passing through the centre-of-gravity of any section as previously described.

Assume, for example, that the load W_1 in Fig. 74 equals 300,000 pounds, and that the load W_2 equals 450,000 pounds, that the distance y_1 equals 6 feet, and that the distance y_2 equals 18 feet. Then, by substitution, $D = \frac{(300{,}000 \times 6) + (450{,}000 \times 18)}{300{,}000 + 450{,}000}$, or 13.2, and, consequently, the correct form for the area of the footing to partake is a trapezoid, whose centre-of-gravity or neutral axis is at a distance from the small end equal to 13.2 feet.

After the centre-of-gravity of the area for the footing has been located in this manner, and the tier of beams so arranged that the unit pressure from the soil beneath the grillage will be uniform, the bending-moments may be calculated. In the grillage-footing shown in Figure 75, which supports two columns, the greatest bending-moments occur at three points, namely, beneath the respective columns and at some point between them, the bending-moment in each case being at the point of no shear. The loads from the two columns and the pressure of the soil from beneath tend to distort the bottom tier of beams in the grillage by causing them to deflect convexly beneath the columns, and to bend upwards concavely between them. In this system of grillage, as previously stated, it is necessary to locate those points beneath the two columns, and at some point between them, as M_1, M_2 and M_3, at which the shear equals zero.

The unit pressure from the soil upon the bottom tier of beams may be represented by p, while the pressure per unit of length from column W_1 may be represented by p_1, the pressure per unit of length under the column W_2 being represented by p_2. These values p_1 and p_2 are obtained by the following formulas, which are clear upon reference to Figure 75 : —

$$p = \frac{W_1 + W_2}{l}$$

$$p_1 = \frac{W_1}{x_1}$$

while $$p_2 = \frac{W_2}{x_2}$$

When the values of p have been ascertained in this manner, the distances from the left-hand end of the lower tier of beams,

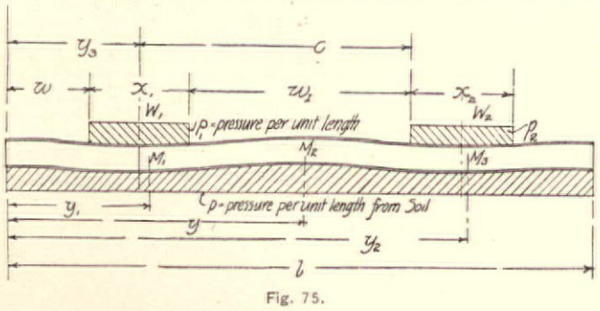

Fig. 75.

to the points at which the shear is equal to zero, may be represented by y_1 and y_2; in obtaining the value y_1 it is true that $y_1 p = p_1(y_1 - w)$, or $y_1 = \frac{w p_1}{p_1 - p}$; in determining the value y it is true that $y p = W_1$, or $y = \frac{W_1}{p}$; in determining the distance y_2 the value $y_2 p = W_1 + [y_2 - (w + x_1 + w_1)] p_2$

$$y_2 = \frac{(w + x + w_1) p_2 - W_1}{p_2 - p}$$

In application of these formulas assume that it is required to determine the three points at which the greatest bending-moments exist, or at which the shear is said to change signs, or to equal zero in the steel-beam grillage-footing shown in Figure 76.

The value to be substituted in the three formulas just given for ascertaining the values y_1, y and y_2 are $W_1 = 300{,}000$; $W_2 = 500{,}000$; $w = 3$; $p_1 = \frac{W_1}{4}$, or 75,000; $p = \frac{W_1 + W_2}{26}$, or 30,769; $p_2 = \frac{W_2}{x_2}$, or 83,333; $x = 4$, and $w_1 = 10$, and the calculation and results of the formulas are as follows: —

$$y_1 = \frac{3 \times 75{,}000}{75{,}000 - 30{,}769}, \text{ or } 5.10 \text{ feet.}$$

$$y = \frac{300{,}000}{30{,}769}, \text{ or } 9.75 \text{ feet.}$$

$$y_2 = \frac{(3 + 4 + 10)\, 83{,}333 - 300{,}000}{83{,}333 - 30{,}769}, \text{ or } 21.24 \text{ feet.}$$

When these several distances from the end of the beam to the point of no shear, or greatest bending-moment, have been obtained in this way the several bending-moments at these points may be obtained by taking the algebraic sum of all the moments about each point. For instance, if all the downward forces are regarded as positive, and all the upward forces are considered as negative, the positive moments at a point y_1 distant from the left-hand end of the grillage or bottom tier of beams of the footing shown in Figure 76 will equal $\frac{p_1 (y_1 - x)^2}{2}$, while the negative moments from the upward pressure of the soil about the same point will equal $\frac{p y_1^2}{2}$; so that the algebraic sum of these moments about the point y_1 distance from the left-hand

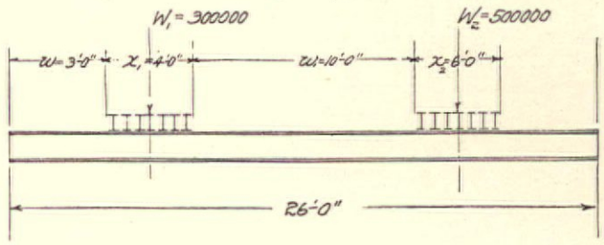

Fig. 76.

end of the tier will equal M_1, or $\frac{P_1 (y_1 - x)^2}{2} - \frac{p y_1^2}{2}$. Regarding, as before, the downward forces as positive and the upward forces as negative, the bending-moment about $M_2 = W_1\left(y_3 - \frac{y}{2}\right)$ for the positive moment about the point in question is equal to $W_1 (y - y_3)$, while the negative moment about the same point is equal to $p y \times \frac{y}{2}$, or $\frac{p y^2}{2}$, so that the algebraic sum of the two values equals $W_1 (y - y_3) - \frac{p y^2}{2}$; but $p y$ must be the same as W_1, for the shear at the point under consideration is zero; that is, the direct downward action is equalized by the direct upward reaction; therefore, by placing the negative value within the parenthesis, and changing the signs, M_2 is found to equal $W_1\left(-y + y_3 + \frac{y}{2}\right)$, or $W_1\left(y_3 - \frac{y}{2}\right)$, which is in form and value the same as given above. In a similar manner, the bending-moment about a point at a distance from the left-hand end of the tier equal to y_2 is found by taking the algebraic sum of the moments about the point. Here the positive moments, or those tending to operate the beam about the left of the point in question in a direction opposite to the moment of the hands of a clock, are equal to $W_1 (y_2 - y_3) + \frac{p_2 (y_2 - y_3 - c)^2}{2}$, while the negative moment about the same point tending to turn the left-hand end of the beam in an upward direction, or with the movement of the hands of a clock, is equal to $\frac{p y_2^2}{2}$, so that the bending-moment about the third and last point, or M_3, equals the algebraic sum of these values, or

$$M_3 = W_1 (y_2 - y_3) + \frac{P_2 (y_2 - y_3 - c)^2}{2} - \frac{P y_2^2}{2}$$

In applying these formulas to the conditions of the problem designated in Figure 76, the several values to be substituted are as follows: as previously found $p = 30{,}769$; $p_1 = 75{,}000$, and $p_2 = 83{,}333$, while, as determined from the condition of the problem stated in the figure, $W_1 = 300{,}000$; $x = 4$; $y = w + \frac{x}{2}$, or 5; and $c = 10 + \frac{x}{2} + \frac{x_2}{2}$, or 15; the values of y_1, y_2 and y_3 being found from the previous calculations to equal, respectively, 5.10, 9.75 and 21.24. Therefore, by substitution in the formulas, $M_1 = \frac{p_1 (y_1 - x)^2}{2} - \frac{p y^2}{2}$, $M_2 = W_1\left(y_3 - \frac{y}{2}\right)$ and $M_3 = W_1 (y_2 - y_3) + \frac{P_2 (y_2 - y_3 - c)^2}{2} - \frac{p y_2^2}{2}$, the values M_1, M_2 and M_3 are determined from the following calculations: —

$$M_1 = \frac{75{,}000\ (5.10 - 4)^2}{2} - \frac{30.769 \times 5.10 \times 5.10}{2}, \text{ or}$$

400,150 foot-pounds.

$$M_2 = 300{,}000\left(5 - \frac{9.75}{2}\right), \text{ or } 39{,}000 \text{ foot-pounds.}$$

$$M_3 = 300{,}000\ (9.75 - 5) + \frac{83{,}333\ (21.24 - 5 - 15)}{2} - \frac{30.769 \times 21.24 \times 21.24}{2}, \text{ or } 5{,}465{,}205$$

or the value in inch-pounds will equal for M_1, 4,801,800; M_2, 468,000; and M_3, 65,582,400.

From these deductions and calculations it will be observed that the greatest bending-moments are at the two end points of no shear, and that the bending-moment at the middle point was comparatively small. This will always be the case unless the column-bearings are an extremely short distance from the end of the grillage, and the maximum bending-moment of these two will usually be under the column-base supporting the heaviest load. When the column-bases are especially designed to sustain the necessary transverse stress, that is, when they are capable of carrying the load on their perim-ters, and when long beams can be used in the upper tier of the grillage, the bending-moments at M_1 and M_3 are reduced to a certain extent, but the value of M_2 remains unchanged.

It is frequently desired that a raft, or grillage-foundation footing, support three columns or bases, instead of two, as described above, and the conditions that lead to such requirements are shown in Figure 77. Here, it is necessary to transmit the pressure on the soil away from the lot-line, so that there will be no interference with the footings under the adjacent building, and in order to accomplish this the exterior column in the basement is set back from the party-line and the upper columns and curtain-wall is supported upon the end of cantilever girders. The principal aim in proportioning such a grillage-footing, as previously stated, is to observe that the centre-of-gravity of the supporting-area of the footing is coincident with the centre-of-gravity of the loads upon the column or base. This desirable result may be secured either by irregularity in the spacing of the columns to suit their respective loads, which is hardly allowable by the designing of the building, and by spreading the

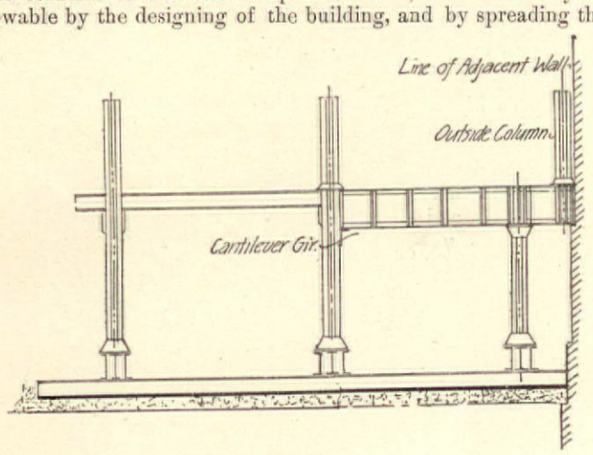

Fig. 77.

grillage at one end and increasing its projection. In order to determine the distance from either end of the centre-of-gravity of the loads upon a three-column grillage, which must coincide as nearly as possible with the centre-of-gravity of the upward reaction of the soil, proceed as follows: multiply the amount of each column or base load by its respective distance from a specific end of the grillage and divide the sum of these moments by the sum of all the column-loads. This rule is more clearly expressed by formula, and if D equal the desired distance upon reference to Figure 78, the amount may be expressed by the formula

$$D = \frac{W_1 y_1 + W_2 y_3 + W_3 y_5}{W_1 + W_2 + W_3}$$

The values as p_1, p_2, p_3 and p, which are the values per unit of length, respectively, for the load W_1, W_2, W_3, and the upward

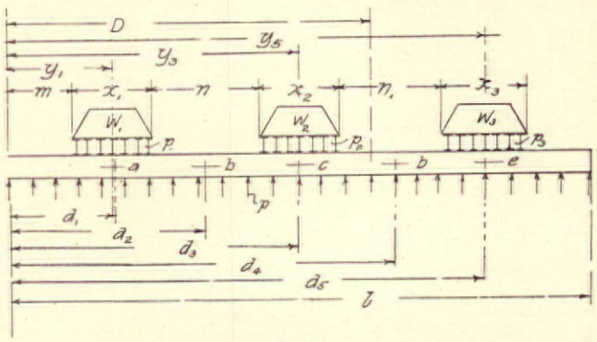

Fig. 78.

pressure of the soil, or $W_1 + W_2 + W_3$, may be expressed by the formula

$$p_1 = \frac{W_1}{x};\ p_2 = \frac{W_2}{x_2};\ p_3 = \frac{W_3}{x_3}$$

while

$$p = \frac{W_1 + W_2 + W_3}{l}$$

The several column-loads and the upward reaction of the soil produce deflection, or, rather, tend to produce, for the beams are held rigidly against flexure by the concrete bed and filling, and, consequently, there is no shear at five points, as at a, b, c, d, e, so that the maximum bending-moments take place at these points. These bending-moments may be conveniently expressed by the letters M_1, M_2, M_3, M_4, M_5, signifying the moments at the first, second, third, etc., position from the left-hand end of the grillage.

Before the bending-moments can be calculated, however, it is necessary to determine their position from one end or the other of the beam, and this may be done by equating the amount of pressure from the soil beneath the beam, included in the distance from the end to the point which it is desired to locate, with the downward pressure due to the several loads acting upon the top of the beams included in the same length of beam or grillage. For instance, the upward reaction due to the pressure of the soil beneath the grillage from the left-hand end of the beam to a point at d_1 distant from the left-hand end of the beam is equal to $p\,d_1$; the reaction from the soil from beneath the grillage to a point at d_2 distant from the left-hand end of the beams is equal to $d_2\,p$; likewise the upward pressure to a point d_3 distant from the left-hand end of the grillage is expressed by $d_3\,p$, while in the same way the upward pressure from the end of the beam to a point distant d_4 equals $d_4\,p$, etc.; in order, therefore, that the vertical shear upon the grillage shall equal zero at the points a, b, c, d, e, in Figure 78, or at the points of greatest bending-moment represented by M_1, M_2, M_3, M_4, M_5, there must be at each point d_1, d_2, d_3, etc, distant from the left-hand end a downward pressure in opposition and equal to $d_1 p$, $d_2 p$, $d_3 p$, etc.; this downward pressure at d_1 will equal a portion of the load W_1; at d_2 it will include all of the load W_1, while at d_3 it will include the entire load of W_1 and a portion of the load W_3; the downward pressure at the point d_4 being likewise equal to the entire load W_1 and W_2. From this it will be quite evident that the following equations may be correctly deduced: —

$$d_1 p = (d_1 - m) \times p_1, \text{ or } d_1 = \frac{m p_1}{p_1 - p}$$

$$d_2 p = W_1, \text{ or } d_2 = \frac{W_1}{p}$$

$$d_3 p = W_1 + [d_1 - (m + x_1 + n)]\, p_2, \text{ or}$$

$$d_3 = (m + x_1 + n) \times \frac{p_2 - W_1}{p_2 - p}$$

$$d_4 p = W_1 + W_2, \text{ or } d_4 = \frac{W_1 + W_2}{p}$$

$$d_5 p = W_1 + W_2 + [d_5 - (m + x_1 + n + x_2 + n_1)]\, p_3, \text{ or}$$

$$d_5 = \frac{(m + x_1 + n + x_2 + n_1) \times p_3 - W_1 - W_2}{p_3 - p}$$

When these several distances have been ascertained, the negative and positive moments about each of these points, the location of which is found, may be calculated, and their algebraic sum will equal the bending-moment at the five points where it reaches the maximum throughout the girder. In determining the formulas for the bending-moment it should be observed that in figuring the moment of any uniformly distributed load the length of its lever-arm is considered from the centre-of-moments to the centre-of-gravity of the load. For instance, in a cantilever supporting a uniformly distributed load of W upon a length equal to l, the lever-arm by which the moment is created at the point of support is equal to $\frac{l}{2}$, and the bending-moment at the same point is $\frac{Wl}{2}$. Referring to Figure 78, the positive moments at M_1, M_2, M_3, M_4 and M_5 are respectively equal to $\frac{p\,d_1^2}{2}$, $\frac{p\,d_2^2}{2}$, $\frac{p\,d_3^2}{2}$, $\frac{p\,d_4^2}{2}$ and $\frac{p\,d_5^2}{2}$, while the negative moments about the same points are equal, respectively, to $\frac{p\,(d_1-m)^2}{2}$, $W\,(d_2-d_1)$, $\frac{p_2\,(d_3-m+x_1+n)^2}{2}+W_1\,(d_3-d_1)$, $W_1(d_4-d_1)+W_2\,(d_4-d_3)$ and $\frac{p_2\,(d_5-m+x_1+n+x_2+n_1)^2}{2}$ $W_1\,(d_5-d_1)+W_2\,(d_5-d_3)$, and by combining the two sets of values the following equations for the bending-moments are obtained: —

$$M=\frac{p\,d_1^2}{2}-\frac{p\,(d_1-m)^2}{2}$$

$$M_2=\frac{p\,d_2^2}{2}-W_1\,(d_2-d_1)\;W_1\,b-W_1\,\frac{d_2}{2}=W_1\left(b-\frac{d_2}{2}\right)$$

$$M_3=\frac{p\,d_3^2}{2}-\frac{p_2\,(d_3-m+x_1+n)^2}{2}+W_1\,(d_3-d_1)$$

$$M_4=\frac{p\,d_4^2}{2}-W_1\,(d_4-d_1)+W_2\,(d_4-d_3)$$

$$M_5=\frac{p\,d_5^2}{2}-\frac{p_3(d_5-m+x_1+n+x_2+n_1)^2}{2}$$
$$+W_1\,(d_5-d_1)+W_2\,(d_5-d_3)$$

Usually in this style of grillage footing the bending-moments at M_2 and M_4 will be small and the maximum bending-moment will be at one or the other of the points M_1, M_2, or M_3, depending upon which point supports the greatest column-load.

In the several solutions for the bending-moment given, the upward reaction of the soil was considered as of uniform intensity and not of varying pressure, as would exist were there any deflections in the beams and concrete forming the footing. Such deflection is not likely to occur when it is considered that the beams are thoroughly embedded in the concrete and are greatly stiffened thereby.

In the next article, the design of spread footings, armored concrete or of the Melan construction will be considered, and a comparison of cost between such footings and the steel-beam grillage summarized.

M. M. Sloan.

Correction. — We had the misfortune in our last issue to deprive Messrs. Stickney & Austin, architects, of Boston, of the authorship of the design of the house of Ex-mayor E. U. Curtis, on the Bay State Road, by wrongfully attaching to the illustration of the doorway of the house the names of Messrs. Winslow & Bigelow as architects.

COMMUNICATIONS

[*The editors cannot pay attention to demands of correspondents who forget to give their names and addresses as guaranty of good faith; nor do they hold themselves responsible for opinions expressed by their correspondents.*]

"WHEN DO BUILDING OPERATIONS BEGIN?"

Boston, Mass., September 16, 1902.

To the Editors of the American Architect: —

Dear Sirs, — Your correspondent Mr. Cervin inquires what constitutes the first beginning of work on a building or wall. About ten years ago a new building-law went into effect in Boston which materially changed some of the existing provisions in regard to construction. I was at that time engaged upon the construction of a large office-building, permit for which had been granted some time before the law went into effect, but I was notified by the Building Department that the City Solicitor had decided that for a building to have been begun it was not sufficient for the excavation to have been made, but that some of the actual permanent construction of the building must be in place. This is one decision that might fix the point upon which your correspondent inquires.

Yours very truly, C. H. Blackall.

NOTES AND CLIPPINGS

Scotch Gardens. — Scotland has many good gardens. The Duchess of Sutherland cares much for her garden at Dunrobin Castle. Owing to the mild climate and rich soil of this corner of Scotland, the Dunrobin gardens seem at their best in the earliest spring, when the millions of snowdrops are in full bloom. At Glamis Castle, the chief feature is a famous sundial. It stands on the lawn, has 84 dials, and is supported by lions carved in stone. One hardly expects to find a garden on the lines of Versailles in the heart of Scotland; but such can be seen at Hopetoun House, belonging to Lord Hopetoun. Gray, the poet, praised these beautiful, if somewhat formal, parterres; and Byron observed that "such symmetry was not for solitude." Terraced gardens are approved in Scotland; they are seen at Balcarres House, belonging to Lord Crawford, and are a feature at Drumlanrig, the princely domain of the Duke of Buccleuch. — *Illustrated Carpenter and Builder.*

Early Hours. — Builders will be gratified by the decision which was given in the Court of Appeal on Tuesday last. An enlargement of Harrod's Stores is in progress, and, as is usual in all works of importance where expedition is essential, a steam crane is employed. Some of the residents in the neighborhood applied for an injunction to restrain the crane from operating as early as 6.30 A. M. Mr. Justice Buckley granted an injunction which would prevent the use of the crane before 7 A. M. The defendants appealed on the ground that they would suffer a serious penalty, as they would be paying a large number of men for half an hour in which no work could be executed. Lord Justice Vaughan Williams stated that the Court could not say that it was unreasonable to begin using a crane at 6.30 A. M. There was no vested right which secured people living in a residential street from being disturbed before 8 A. M. It was to the interest of every one to have the work executed as quickly as possible. He thought that the

injunction ought to be discharged. Lord Justice Mathew agreed, and was of opinion there was no ground for the application or for the injunction. — *The Architect.*

Tripartite Stroke of Lightning. — A correspondent of *Nature* writes as follows concerning a tripartite stroke of lightning in Cambridgeshire, England: "At 6 50 P. M. on August 7, after two or three preliminary low thunder rumblings, which by no means prepared us for what was to come, a most tremendous crash of combined thunder, lightning and electric discharge burst right over my residence here. My butler, who was looking in the direction of our front gate, 80 yards to the north of our front door, saw a burst of smoke, mingled with a shower of leaves, rise into the air out of the adjoining shrubbery. My coachman, who was sitting just within the open door of the lodge, close to the front gate, was dazed by a vivid burst of flame at his feet which seemed to leap into the doorway. My neighbor's gardener, looking out of the lodge opposite, saw a nearly horizontal flash of fire enter the shrubbery close to my front gate. A subsequent examination of the surroundings of the front gate and my coachman's lodge has revealed: (1) A tearing-up of the ground close to the massive iron post of the front gate, the splitting of a large flint at its foot, and a litter of ivy-leaves on the gravel. (2) The clean cutting in two of an oak post, 35 yards distant to the northeast, from which an iron hand-gate was hanging. (3) The scorching of the outside foliage of a horse-chestnut some 15 yards still farther off, in a direct line with the other two objects struck. In thirty years' experience of thunder-storms, which are rather frequent here, I have never observed the simultaneous striking of three different points by the electric discharge. A deathlike stillness succeeded the crash, the storm appearing to have exhausted itself in a single tremendous explosion. Heavy rain was falling when the crash occurred."

The Roman Monument to Victor Emmanuel. — The architect of the great monument to Victor Emmanuel, the "Father of his Country," has publicly announced that the work has lately taken such strides that it will be finished in seven years. This, added to the thirty-odd years since the monument was begun, seems a tremendous time, to modern ideas, especially as the money was forthcoming from the first. This impatience is, however, reproved by the ancient buildings surrounding the great work, many of which were hundreds of years in the building. The new monument stands at the extreme end of the historic Corso, which before closed in a medley of odd buildings. Many of these have already been torn down to make the necessary space, and others are in process of demolition, so that the colossal monument will have in front the stretch of the Corso to the Piazza del Popolo on one hand, the Capitol and the Church of the Ara Cœli, with their majestic sweep of steps, and on the other Trajan's Forum, with its unrivalled storm beaten column and the twin churches at its northern end. The monument will be a grandiose building of porticos, Corinthian columns, statues and bas-reliefs, which will house two or more museums, and perhaps a library, surmounted by a magnificent triumphal group of horses and chariot driven by "Victory," the whole rising about 290 feet. In front, standing well out from the building, on its own pedestal and approached by steps, will be an equestrian statue of the Re Galantuomo. The taste of the whole has by some critics been seriously questioned, if not condemned, but no one can deny that the effect at the end of the Corso, the centre of the life of the city, will be stupendous. — *Pall-Mall Gazette.*

London's vast Problems. — The report of the London County Council published this week furnishes some striking figures indicating the immensity of the municipal problem with which the London authorities are confronted. According to the census of 1901, the population of the Administrative County of London was 4,536,541, while Greater London, immediately surrounding the County, showed an additional population of 6,500,000. The lunacy statistics of the Administrative County show an increase of 50 per cent in the last ten years, the total number of lunatics being 21,369, for which drink and business and domestic troubles were accounted to be largely responsible. The London County Council has to maintain 2,017 miles of paving, a large section of which is in a constant state of upheaval, owing to the number of gas, electric and water companies having the power to open roadways. The problem of housing the working-people is dealt with on a large scale, the Council acting as landlord to a population of 12,596 housed in cottages, block dwellings and various other structures. The year's working showed a net surplus of $11,565 for these dwellings compared with a deficit of $5,785 for the previous year. The Council is a large owner of omnibus and street-car lines, which carried last year over 118,000,000 passengers, while all the omnibus lines of Greater London showed the enormous total of 530,000,000 passengers. The city's debt statistics show a discouraging increase, the total debt outstanding being $231,344,355, equivalent to 124.98 per cent of the ratable value, against 104 64 per cent when the London County Council came into existence. The tax-rate now amounts to about 36½ cents per pound sterling ($5). — *N. Y. Tribune.*

Studios for poor Paris Artists. — Alfred Boucher, an artist, is making a novel effort to help less fortunate fellow-craftsmen. From various architectural fragments and waste material from minor exposition buildings he has constructed, in the Vaugirard Quarter, Paris, a large domed building providing 48 studios and a common hall. These are to be rented to painters and sculptors for prices ranging from $30 to $50 a year, the latter sum providing sufficient room for living quarters. The privileges of the common room, with special arrangements for art-work, and free instruction by M. Boucher, are to cost but $10 a year. A building close by is to serve as a museum for art-works owned by M. Boucher, who has also lavishly decorated the corridors of the studio building with paintings. — *Success.*

The Wane of the Lightning-rod. — The day of the lightning-rod is passing, says the New York *Evening Post.* The Government's latest census returns show that Franklin's invention for protecting the house is little used to-day. No electrical-manufacturing establishment reports it among the products, and so far as the census expert has been able to learn, only one American electrical-engineering firm makes a business of setting-up the rods or designing them. So far as large cities are concerned, disastrous lightning-strokes are reported to be more rare, and the decrease is accounted for by the network of electrically charged wires and other apparatus with which the city is now interwoven and surrounded.

Bort. — The only place in the world where that form of carbon known as the black diamond, or bort, is found in marketable quantities is in Bahia, in South America. The substance is used for points for stone drills and saws, and is powdered and used to polish diamonds and other precious stones. There is a wide and growing demand for it. The black diamond is found with the ordinary diamonds in the Bahia fields and brings about ten dollars a carat. The largest carbon ever found weighed 3,150; it was bought from the miner for $16,000; was afterward purchased for $25,000; and was sent to Paris, where it was broken up and sold to the trade. The average size is about six carats. The annual output is decreasing as the demand grows larger, and the price is mounting. It is probably only a question of time when a black-diamond combination will be formed to work the small area with modern machinery. The present methods are very primitive. — *Exchange.*

The Days of the Dalziels. — The death of Mr. George Dalziel, which has just occurred at Hampstead, in his eighty-seventh year, carries the mind back to the great period of English illustration that began in the sixties, when, under the influence of the work of Adolph Menzel, so many famous artists were filling the pages of periodicals with beautiful drawings. There were two firms of engravers which were specially connected with this period — the firm of Dalziel Brothers and the firm of Swain. George Dalziel (says the London *Times*) came to London first of the three brothers, whose lives and work found interesting record in a book about them published last year. They were the sons of a Northumbrian artist, and were all men of more than ordinary culture and talent. They certainly raised wood-engraving to the highest pitch of art it has ever reached in this country. The mechanical methods of photography and process-engraving have now almost entirely superseded the wood-engraver, and such wood-engraving as there is does not deserve much notice. But there remain in the old volumes of *Once a Week, Good Words,* the *Cornhill Magazine* and other periodicals, as well as in the books issued by the Dalziels, ample evidence to justify the remark of Mr. Pennell that "the day is coming when the books issued between 1860 and 1870 in England will be sought for and treasured up, when the few original drawings that are still in existence will be striven for by collectors, as they struggle for Rembrandt's etchings to-day." The names of the Dalziels are not likely, therefore, to be forgotten.

The Growth of Vienna. — The boundaries of Vienna are to be again widened, and this time to such an extent that the area of the Austrian capital will be almost doubled, and will be second to that of London alone in Europe. Vienna, though it is called the Imperial City on the Blue Danube, lies, as a matter of fact, only on the right bank of that river, which forms its boundary on the northwest. A large semicircle on the left bank, embracing the manufacturing town of Floridsdorf and eleven other places, with a total area of 154 square kilometres, is now to be added to Vienna, and will raise its area from 178 to 332 square kilometres. The new districts, however, are so thinly populated that they will add only 58,000 persons to the population of Vienna, raising it to about 1,800,000. The object of including so large a tract, chiefly rural in character, and much of it liable to periodical floods, is connected with the impending construction of the Danube-Oder Canal, which will enter the Danube opposite the town and within the new district. It is expected that it will create a large industrial quarter there. The old bed of the Danube, through which the river used to flow before its canalization, will be converted into docks and harbors. As all the towns and villages concerned have signified their readiness to fall in with the scheme, and a majority in the town is in favor of it, there is little doubt that the project will shortly be carried into effect, possibly in the course of this summer. — *Illustrated Carpenter and Builder.*

Artesian-well Power. — Mr. W. E. W. Yerby, of Greensboro, Ala., writes to the *Scientific American* to say that "there is in this [Hale] county an artesian well 10 inches in diameter that throws out a volume of water sufficient to run a grist-mill, cotton-ginnery and cotton-press and a saw-mill. The well is about 600 feet deep, and was bored fifty years ago by Col. Samuel Pickens on the plantation 12 miles southwest of Greensboro, Ala., known as the 'Goodrum Place,' now owned by Lee M. Otts, Esq. The water comes up with such force from the well that a silver dollar thrown into its mouth will not sink, but will be thrown out. The gusher has diminished very little in the amount of water furnished during the half century it has been running. To give an idea of the amount of water that is thrown from the well, I will state that the trough surrounding it is 4 feet across, and when the water falls back it comes near filling the trough from side to side. The mill and ginnery run by the water from this well is situated on a hill-side about a hundred yards away, and the water is carried to it by means of a canal cut in the solid lime rock. Just under the mill-house is a well 3 feet across and 40 feet deep. In this well, at a depth of 25 feet, is a turbine wheel, and the water from the canal is turned on it when it is desired to run the machinery. A tunnel from the bottom of this 40-foot well has been cut a distance of 100 yards — ranging upward — and empties the waste-water from the mill into a branch."

NOTES AND CLIPPINGS. 104

WE desire to say to subscribers whose orders for back issues of *Topical Architecture* we have not yet filled that the delay and annoyance is only temporary. The reprinting of the many issues of this popular periodical that are already out of print is proceeding with as little delay as possible.

THE coal-strike is furnishing some lessons in regard to the effects of union tyranny upon the workmen themselves which, we hope, will not be lost. It seems that, in most anthracite mines, a piecework system is in use, by which the miners are paid by the carload of coal taken by them from the mine, the car used for a measure being a small affair run by hand through the galleries of the mine. Very high prices are paid for this work, so that it would be easy for a moderately active man to earn from five to seven dollars a day, if it were not for the unions, which prohibit their members, and, of course, prevent any one else, from getting out more than six carloads of coal a day. This takes, on an average, five hours, and the miners are forbidden by the unions, under penalty of expulsion, to do any work at their trade during the remaining nineteen hours. Some of the men are too ambitious to spend nineteen hours out of every twenty-four in idleness, and pick up what work they can, that will not attract the unfavorable notice of the unions, after they leave the mine for the day. One man, for example, easily loads his six cars, earning three dollars and a half by so doing, in the morning, and spends his afternoon in doing jobs of gardening in the neighborhood of the mine, at fifteen cents an hour; while others find outside employment in similar ways. One miner, who had been put to heavy expense by sickness in his family, begged of the union, as a favor, permission to get out for a time a little more than the regular six cars of coal, so that he might make up his losses gradually by his extra earnings. Permission was refused; but the poor man worked surreptitiously a little harder than usual, hoping that his efforts on behalf of his family would not be discovered. They were, however, soon betrayed, and the victim was warned, by having the rails on which his car ran repeatedly torn up, so that the coal could not be got out, that the necessities of his family were nothing to his tyrants.

THE inexperienced reader might ask what object an association, professedly formed in the interest of a certain class of workingmen, could have in limiting the income of its members to one-half what they would receive if it did not interfere. The answer is the same as that which must be given to a great many questions in regard to labor unions, that these organizations are, to a great extent, controlled by men who have not a single idea or interest in common with the workingmen whom they assume to represent, but who use them as cat's-paws to gain for themselves money or political power, and that these schemers gain control of the unions through the laziest and most worthless of the members, whose only chance of getting employment at their trade lies in suppressing or degrading in some way the men better than themselves. It is obvious that if the good men can be prevented from doing more than five hours' work a day, the coal-operators, who have to get out a certain amount of coal to fulfil their contracts, must hire an additional force of inferior ones to make up the amount; and that, in this way, instead, let us say, of fifty good men doing all the work of a mine, the fifty good men, compelled to lie idle half the day, must be supplemented by an indefinite further number of inferior men. This means, of course, that the latter virtually ride through life on the backs of their more intelligent comrades, and it is by no means in the coal-mining industry alone that workingmen's unions are managed in this way, and, as is boldly avowed, for this purpose.

IT might be well for those who read that fourteen dollars a ton is bid for anthracite coal in the Philadelphia market, and who look with anxious apprehension on the dwindling remnant of coal in their own bins, to remember that their troubles are due, not to combinations of capitalists, but to Mr. Mitchell, who, trusting to the public distress to aid his schemes, has taken advantage of a bad system, brought to dangerous power by the support of politicians, to make demands which cannot be granted without abandoning the free workingmen of the anthracite region of Pennsylvania to a greedy and remorseless despotism, and the granting of any portion of which would simply benefit Mr. Mitchell himself, and his confederate politicians, at the expense of the poor householders of the United States. Much as we may dislike trusts, monopolies and coercion of all kinds, it is plain that, in the present case, the mine-operators are fighting the battle of American liberty, and should be supported by all who still believe in that liberty.

AT the same time, it is possible that a good deal can be done by legislation to relieve the general distress, not by "compelling" the coal-operators to grant Mr. Mitchell's demands, a proceeding which would simply lead to more exorbitant demands, but by taking off the import duty on all coal so that Welsh coal can be imported and sold in this country. With the duty removed Welsh coal, at present prices in Wales, could be delivered in any city east of the Rocky Mountains for from six to seven dollars a ton, and, in the coast cities, perhaps for a little less. An act of Congress, which could be passed, signed and put in execution within a few hours after the assembling of Congress on the second of December, would give the needed relief to millions of humble households; and a popular movement in favor of this would be far more likely to succeed, and far more in harmony with American ideas of individual liberty, than the agitation, started and kept up by designing politicians, about "compulsory" legislation in Pennsylvania. It may be observed, however, that if the Legislature of Pennsylvania really wished to end the coal-strike, or if it could be brought to that state of mind by the pressure of public opinion, it could accomplish that end very quickly by the repeal of the statute prohibiting any one from working as a miner in the anthracite region who has not already been employed for two years in an anthracite mine, and is not registered in certain books kept for the purpose. This statute, in all probability, never had any object except to encourage and prolong strikes in anthracite mines, by making it impossible for the operators to employ outside help; and its repeal would open the doors of the mines to multitudes of free and capable men, at the same time that, by removing from the business of anthracite mining the heavy hand of legislative and union tyranny, it would at once restore to the rest of the community the steady and uninterrupted supply of one of the chief necessaries of life.

AS usual, it is the patient and enduring public which, in the end, suffers most from this tyranny. Supposing, let us say, that the anthracite miners were free to earn as much as they wished, it is probable that each man employed would eagerly seize the opportunity to get out twice as much coal as the union rules now permit, receiving twice as much pay as he is now allowed to earn. This would leave the cost, for miners' labor, of getting out the coal the same as it now is, but the incidental expenses, such as pumping, hoisting, transportation, salaries, interest and dividends would be only half as much, per ton of coal, as they now are, for the reason that these go on just the same whether the miners are working or not; and if the miners brought down twice as much coal in a day, the incidental expenses would be divided among twice as many tons. These incidental expenses form the largest part of the cost of the coal, so that every family that uses hard coal pays a considerable portion of its cost as a consequence of this system. Supposing that the extra cost of anthracite coal due to the union rule of keeping the miners idle half their time, while all the other expenses of mining continue, to be only ten cents a ton, which is probably far within the truth, the tax which the consumers, nearly all of whom are poor and hard-working people, are compelled to pay to support the tyranny of the miners' union, is, in normal times, a hundred thousand dollars a week; or, in other words, if the anthracite miners enjoyed anything like the liberty which the Constitution of the United States guarantees to every citizen, they would not only be much richer than they now are, but their fellow-citizens would have a hundred thousand dollars a week to apply to family expenses which many of them find it difficult to provide for.

THE *Scientific American* asserts without reservation that the Capitol at Washington is soon to be extended, on the east side, by the addition of a mass of building, connecting the present wings, and entirely covering the old sandstone front between the wings, which will be visible only in the courtyards. It seems that the late Dr. Walter, the architect of the dome and of the wings, left plans for such an extension as is now contemplated, which are to be carried out substantially as he left them, some changes only being made in the arrangement of the rooms. We need not say what a relief it is to hear no more of the "pylons" and such things, which have so often been said to be in contemplation for the "improvement" of the Capitol, and it will certainly be an advantage to have the sandstone portion covered up with marble like the material of the wings. Dr. Walter's design for the new middle portion suits admirably the noble, almost romantic, dignity of the wings, besides adding much to the effect of the dome; and the profession will be glad to see it carried out.

ONE of the engineers of the new buildings erected in England for the Westinghouse Company gives his experience in an interesting paper in the *Journal of the Western Society of Engineers*. It will be remembered that the Westinghouse Company, having occasion to build an important group of factories in England, applied to English contractors, who agreed that it would take five years to carry out the plans submitted to them; and that the Westinghouse Company then contracted with an American firm of builders to do the work. Mr. Sloan, the author of the paper, was engaged as engineer by the contracting firm, and spent a year and a half in his duties in England. On the arrival of Mr. Stewart, the American contractor, he found a clerk-of-works, with about a dozen assistants, installed in little offices in different parts of the ground. These superintendents arrived at their offices at about nine o'clock in the morning, and went home about five. Mr. Stewart requested them to present themselves every day when work began, and to stay until it ended, and this reasonable request, as we should think, was answered by the resignation of about half of them, one man saying, in his letter of resignation, that "a man cannot be a gentleman and work under the American administration." Mr. Stewart, however, cared more for efficient superintendents than for gentlemen, if he could not have both, and the places of the retiring men were soon filled.

AMONG the workmen a curious custom prevailed. The men began work at seven o'clock in the morning, but at half-past eight they all stopped for half an hour to take their "breakfast," which consisted of bread and tea. The latter had to be warmed, so the men built little fires on the ground for the purpose. Nominally, the time consumed in this occupation was half an hour, but the interruption of work, including the delays incident to getting started again, was much more than this, and, as three thousand men were often at work at once, the loss of time was a serious matter. Mr. Stewart began by setting up a water-heater on the grounds, from which hot water could be obtained at any time, and forbidding the lighting of any other fires; and the example of the Americans seems also to have inspired the men to a certain extent, for the different trades, one by one, abandoned their morning tea, the bricklayers being the only men who held out to the end. For these, however, other surprises were in preparation. We have before described the process, by placing inspectors over the men, and reporting every day the number of bricks laid by each, by which the average number was raised in a few weeks from about four hundred to nine hundred; and how, as the work became better organized, and the energy of the men was aroused, this average was raised to more than nineteen hundred; but Mr. Sloan gives some interesting particulars of the methods by which this revolution was effected, one being the provision of suitable hoists for material, and another the use of a thinner mortar than that commonly employed in England, saving some labor in spreading, and in setting the bricks. The greatest effect was, however, produced by selecting and keeping the most skilful and active men, which was accomplished by paying more than the union rate of wages, which, in England, is only twenty cents an hour for bricklayers. Notwithstanding this low rate of wages in England, Mr. Sloan says that contracting-prices of doing work generally are "away above those of doing corresponding work in this country"; the difference being due to the "slack method of handling work"; and he thinks that the "slackness" is quite as much on the part of the managers as of the men. As he sensibly says, their own experience showed what English workmen can do with suitable encouragement, but no men will do their best under inefficient management.

THE exhibition of drawings held in Boston this week by the Newspaper Artists' Association was a rather interesting place to visit, although the visitors must have had on leaving a good deal of that sensation of indigestion with which one takes up or lays down the Sunday edition of a Metropolitan newspaper. From a technical standpoint the drawings were far more interesting than we had expected to find them, but the walls were so overloaded and the drawings so poorly arranged that the pleasure of seeing occasional examples of really excellent drawing and delicate coloring was sure to be marred by having to half see at the same time objectionable neighbors on the wall. As most of the drawings were evidently made for weekly publications and Sunday papers of the better class they did not wholly typify the brutalizing influence on public taste which newspaper artists unfortunately have. While there was little that was vulgar or too broadly humorous, one could not but feel that, though the technique was interesting, the artist's idea when not purely puerile was too often frivolous and his treatment of his idea merely flippant. Ten per cent, say, of the higher grade of drawings exhibited by themselves would have furnished a very much more instructive and attractive exhibition.

R. VON WALDHEIM, a publisher of Vienna, Austria, has set a most commendable example in publishing a small pamphlet, devoted to the competitive designs for the Kaiser Franz Joseph Museum, at Vienna. Not only are twenty-nine of the competitive plans reproduced, with four of the principal elevations, but they are accompanied by a very intelligent critical description, by Camillo Sitte. Nothing is more instructive to young architects, or to architects of any age, than the study of competitive designs. Even if they do not always agree with the jurors in their decision, they learn, at least, what sort of plans and elevations suit those jurors best, and they may turn their observations to profit on another occasion. It is hardly necessary to say that a work of this kind, so far as the critical portion of it is concerned, ought to be free from any suspicion of partiality, and perfect sincerity in this respect is, probably, more to be relied upon in Germany than anywhere else; but there is no reason why criticism of similar honesty and intelligence could not be secured by publishers anywhere else; and, with this aid, it seems as if pamphlet tracts of this sort upon the principal competitions might sell satisfactorily among the public, as well as in the profession, and they would do much to interest and enlighten the public in matters of art.

WIRE-GLASS WINDOWS.[1]

THE subject for which I shall have the honor of asking your consideration will be Wire-glass — the fire-retardant, a building-material which tends to reduce to the minimum the hazard of conflagration and conduces to the elimination of some risks attending the lives of us humble fire-fighters. The range of possibilities in fire-protection is too wide to speak of here, if I am to be favored with your attention, and only a small portion of it can be engaged in during this short session. I shall endeavor to advance that which I believe to be the most important factor in the protection of buildings against conflagration, and I shall be amply rewarded if I enkindle in your minds an inclination to seek more information upon the subject than I am enabled to communicate.

It is manifest to all thoughtful minds that the phenomenal development of the real-estate values in our cities has made the tall building a necessity and this necessity has brought with it the need of adopting in building-construction barriers to conflagration, and there are to-day buildings capable of enduring without structural injury the action of fierce, long-continued interior and exterior flames and the application of cold water upon their heated surfaces. Structurally a building of this class is admirable — the foundations are secure, the walls and roof fireproof, but openings in walls and roof are necessary to render it habitable. Obviously the vulnerable parts of a building are the openings in the walls and roof — its doors, windows and skylights. To these openings the spread of flame is almost wholly attributable. This has been the history of so many destructive conflagrations that experts have long agreed that no structure in a closely built city can be considered even approximately secure against fire so long as it is provided with only ordinary windows, skylights and doors. My experience and observation have been such as justify this opinion and I have most strenuously maintained that the quantity of wood contained in what I have termed "a structurally fireproof building," taking into consideration, also, the furniture and fittings, would, in the event of fire, endanger the property and the lives contained within it.

Shutters of iron, or of metal-covered wood, may protect windows if they are carefully closed, but in practice such shutters fall short of the purpose for which they were intended. When the crisis comes the shutter is frequently found open. Under the most favorable conditions an iron shutter at a fire is not the thing that the firemen want to come in contact with. Its rusty fastenings and blistering sides are objectionable, to say the least, and its reach, when it swings open, is liable to knock a man off the ladder. This is a risk to which the fire-fighter should not be subjected. There is no braver, manlier, or more faithful set of men in the pnblic service or out of it than the brave lads enrolled in our Fire Departments. I know of whom I speak and I am well acquainted with the chances they take. They are ready to fight with death every day. Every year sees them saving life heroically or dying in their duty. Their work is as trying, difficult and dangerous as there is in the world. Yet they are not safeguarded. I know what ready fellows they are and I feel that all known means of protection should be adopted to render their calling less hazardous.

Wire-glass is, in my opinion, the fire-stop for window and skylight openings — wire-glass set in metal frames. It supplies the requisite light and ventilation as well as protection against fire; its installation obviates the necessity of the cumbersome and unsightly hinged shutters and the projecting lugs and adjustors which support and secure them. It affords protection regardless of the janitor's neglect, because the thought of fire is not necessarily present in the mind of the tenant to induce him to close the window-sash and when closed it prevents the ingress, egress or communication of flame. It enables the fire-chief to size the situation and direct his men intelligently. The location and volume of the blaze are immediately disclosed and if the conditions warrant it the firemen can effect an opening for the stream with his fire-axe.

Hard conditions, great risks and the sacrifice of large property and many lives are preliminary to the establishment of standards, and by such means wire-glass has come to be recognized as standard and the degree of honor which is its legitimate due should be generally recognized.

Succinctly stated, wire-glass has yielded two fixed values as its contribution to fireproof building construction:

It retards fire without hiding it — permits the blaze to declare itself.

It can be cracked, but it cannot be scattered. If fractured it retains its place.

Now, we have to remember what we can't forget, and we are mindful, therefore, of experiences which enable us to fully appreciate the value first stated. Of the many embarrassments to which the fire-fighter is subject, that which prevents fire from disclosing its location in its incipient stage is the most serious. Within the congested districts of our great cities, our organizations are such as enable us to reach the scene of action and have our nozzles in hand within two or three minutes of the alarm, and if we could immediately get at the fire, we would, in most cases, have little difficulty in confining the blaze within the limits of the apartment in which it originated.

Modern science has equipped our departments with devices necessary to combat fire, the most contagious, virulent and disastrous of all perils to which buildings are subjected; and modern science has devised the means by which fire can be confined within the walls of buildings without rendering the same inaccessible to us, but the adoption of the means available is not general, and upon arriving at a fire we are frequently confronted with tin-covered and iron-clad shutters which obstruct our vision and our efforts to locate and conquer a blaze which becomes a conflagration because of the precious moments lost in concentrating our energies upon the seat of trouble.

This condition has long been a serious menace in all cities and it is now intolerable, because the installation of wire-glass presents no technical difficulties. It is of acknowledged efficiency and no less economical than effective. It has withstood the severest tests and its cost is well within the means of all building-owners. The insurance-companies give "preferred" rates when it is installed and thus practically invest in it. Their scheme is to reduce hazards, and in the belief that wire-glass effectually accomplishes this, they induce its adoption by substantial endorsement. Its ability to abate horrors and loss which attend conflagrations in cities is ample justification of the reasonable laws providing for its adoption, and an exigent public duty is presented to Building Inspectors to prevent these laws being nullified by official inertia.

There is a region paved with good intentions, and many easy-going owners of buildings contribute to this paving-fund by deferring the adoption of known means of protection and at the same time create occasion for regret from heavy financial loss and probable loss of life. I want to see the obligation placed upon owners of buildings to prevent such losses by the means which will effectually render fire non-communicative, and I think I have specified the means. The significance and overwhelming argument in favor of wire-glass as a fire-stop is the fact that when fractured it retains its place and continues to retard draught and its attending flames.

Doubtless, many of the Chiefs present have had occasion to recognize the efficiency of wire-glass as a fire-stop, and, of the many, Chief Musham's experience is especially worthy of reference. The fire which destroyed the Armour Lard Refinery, Union Stock Yards, Chicago, on the night of May 16, threatened for a time the entire district. Chief Musham was present, and he has stated that the wire-glass in the windows of the several walls prevented any communication through them and demonstrated the ability of wire-glass to prevent the spread of flame. The building destroyed was of recent construction, 100′ x 400′, five stories in height and subdivided into four sections by fire-walls, two of which were completely destroyed.

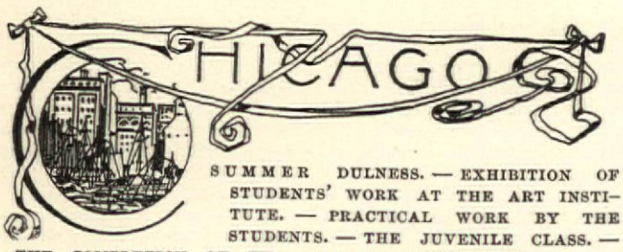
The quantity and nature of the material in combustion — refined lard — resulted in the hottest kind of a fire and its intensity and duration are hardly comprehensible. The Chief tells me that the flames reached to a height of 150 feet above the roof and the combustion was so perfect that scarcly any sparks were observed.

I am quoting Chief Musham because I think, perhaps, his observation of wire-glass in this instance was under a better condition than can be conceived for an actual service-test of wire-glass. The entire interior of the building was of inflammable construction, made more so by being saturated with lard, and its five great floors were loaded with tons of this highly combustible product. Tanks containing thousands of gallons of rendering were exploded and their contents dashed against the walls and windows, and the intensity of the heat was so great that the walls holding the frames and sash which accommodated the glass crumbled, but until they fell the wire-glass retained its place.

This fire establishes conclusive proof of the efficiency of wire-glass as a fire-retardant and its staying qualities, and for the purpose of illustrating my subject I have considered it preferable to my own experience.

[But wire-glass is not subjected to a fire-test every day, and except when fire is present it has undesirable, even dangerous, qualities. When the Engineering Experiment Station has time to study wire-glass, it will find in the many acres of this material at the South Terminal Station in Boston ample food for study and reflection. In the windows that face east, south and west and in the thousands of feet of pent-roof over the street-sidewalks there is hardly a sheet of the glass that is not cracked and shivered into a dozen or a hundred different pieces of glass, just now held in place by the embedded wire and the unequal planes of fracture of the glass itself. But where cracks are, there moisture and acid-gases can penetrate, and when corrosion has done its work on the wire there is likely to be many a repetition, less innocent, too, of the incident which attended President Roosevelt's reception in this city a few weeks ago when, as the newspapers reported, a sizable piece of this shattered wire-glass fell onto the platform not far from the President. Meanwhile, before the time comes when falls of heavy pieces may be looked for, much of this shattering of the glass is already accompanied by the flying of fine splinters of glass, and as the oculists of Boston are said to have recognized a class of injury that they call "elevated-railway eye," it is not impossible that they have been called on to treat for wire-glass eyes travellers who have to use the Boston Terminal Station. As fracture occurs least often on the north side and most frequently where the windows face the rising sun, it is evident that the manufacturers must give further study to the qualities of radiant heat before wire-glass can be held to be a perfectly safe material to use. — Eds.]

[1] A paper, by Edward F. Croker, Chief of Fire Department, City of New York, read at the Thirtieth Annual Convention of the International Association of Fire Engineers, held in Grand Central Palace, New York, September 16, 17, 18, 19, 1902.



SUMMER DULNESS. — EXHIBITION OF STUDENTS' WORK AT THE ART INSTITUTE. — PRACTICAL WORK BY THE STUDENTS. — THE JUVENILE CLASS. — THE COMPLETION OF THE ART INSTITUTE BUILDING. — A PATRIOTIC ELECTRIC FOUNTAIN. — THE BLACKSTONE BRANCH LIBRARY. — THE IROQUOIS THEATRE.

IN building-circles here in our city a summer calm seems to prevail. With the exception of a few large office-buildings which are now in the process of erection, but little actual construction seems to be going on, and also, with a few exceptions, the architects' offices are rather quiet, with but little that is interesting on the boards. Chicago, which is supposed to resemble the watcher of Israel in one respect, that she "slumbers not nor sleeps," really does seem to take on a more reposeful air during the summer months, and schemes are not matured during July and August.

The Art Institute falls into the same attitude and, in spite of a busy summer-school in its school-rooms, the lecture-hall remains undusted, the exhibitions cease to rotate, and the library no longer is full of the busy crowd of students "hustling for cult," as the typical Western girl is supposed to have phrased it. Notwithstanding that there have been no exhibitions for the last two months which have been considered worth heralding, still that of the students' work, which has filled all the galleries, large and small, in the south wing, has been one of unusual interest and also one which should make the true Chicagoan swell with pride. The work, from the children's Saturday-morning class up to that of the young men and women in the life-class, is fine. All the departments give really good exhibitions of the work done in them, and the general spirit of earnestness and enthusiasm which is evinced in all branches speaks volumes for the success of the school. And neither is the success all to be obtained in the future, for it is common report already that students from the Chicago Art Institute are welcomed in the Paris studios with greater cordiality than from any other American art-school, as being men and women better fitted for good work. The Art Institute is following in its teaching one method, which seems especially to give good results. This is the idea of letting the advanced students in all departments do actual practical work, not alone the everlasting drawing of studies. Thus, the embryo sculptors, though most who do so have passed the embryonic state, combine and produce some really impressive works of art. The work this year is exceptionally fine. One piece is a fountain representing our five Great Lakes, and both in conception and execution is good, much better by far than many a fountain seen in parks and at street-corners. Another one of these large compositions, conceived and executed by the students, is in the nature of a monument. It consists of a funeral cortége of ten life-sized figures, six bear a sarcophagus, two draped and bowed figures, their faces buried in their hands, walk in advance, while two hired mourners bring up the rear. The whole composition is fine, with not only artistic merit, but a certain poetic touch and feeling about it which is unusual.

No such applied work is seen in the architectural department and it seems a pity that the students should not be given a chance to combine with the sculptors. It is an often recognized fact, and one much to be regretted, that many a good piece of work for a fountain, statue, or monument, is marred or ruined in its general effect by its poor setting. Why should not the young architect furnish the designs for the bases or pedestals for the excellent work which the students in modelling do. If the architectural students could be properly trained in this direction a long felt want might be supplied and a lack in a certain part of the average architectural education made good. Mr. St. Gaudens knows enough to demand that some really well-educated architect should design a proper setting for his work.

Similar in nature, in the matter of the practical application of their art, is the composition of a frieze for school-house decoration by the life-students in oils. Whether any special place is going to be fortunate enough to obtain the work the catalogue does not state, but it certainly is a charming composition of children at play-time, done in rather flat opaque colors, and would be a delightful feature in any school-corridor, large assembly-hall or kindergarten room.

The work in applied design is delightful, in competitions for book-covers, lacework, book-marks, etc., but is weaker when it borders on architectural design. Some good things are shown in this line in tilework, glass, etc., but the architectural work generally makes the weakest showing. There does not seem to be the same enthusiasm evinced among the students of this department as elsewhere. The strictly architectural compositions have good points, but they have to be judged by a high grade, if we are to accept for a standard that set by the other departments, and, while not poor, we should be glad to see better work in this section next year. However, taken as a whole, the school shows a high standard of work which is very surprising and an enthusiasm which is quite inspiring. The number of students is 2,333, over three hundred of them being in the Saturday-morning juvenile class.

In connection with this juvenile class an experiment is being tried which may eventually do much to spread a knowledge of matters artistic. This is known as an Art Institute Extension, and is being tried in Winnetka, a suburb of Chicago's always in advance in municipal and educational reforms. The use of the corridors of one of the modern school-houses is given to the Art Institute, which sends out teachers, equipment, etc., the classes being just the same as those in the Chicago school, the children's studies going in to be marked and passed upon, and they themselves being taken in for lectures and visits to the galleries from time to time, while avoiding the weekly trip which to many of them would be impossible. Taken all together the Institute is the greatest achievement in an artistic way Chicago has ever accomplished, and very soon the building will fully equal in perfection the treasures which it holds.

Many people do not realize that the façade facing Michigan Avenue is but a small part of the actual building. It was planned to extend back to the Illinois Central tracks and was so arranged as to be possible to build different parts in different years. These portions have been added from time to time, as for instance, the increase in students' quarters, later the Fullerton Hall, then the Ryerson Library, till this year comes the fine gallery, extending through two stories, destined to house the splendid Trocadéro collection of casts, a gift to the Art Institute from the French Government after the World's Fair. With the erection of this gallery the entire plan of the building is nearly worked out, there only remaining the monumental stairway to complete the grand whole. It is to be hoped that before long it will be possible to materialize this last feature, as doubtless it will add much to the impressiveness of the building, though to the ordinary visitor the present entrance and stairway seem adequate.

During the past year there has been exhibited at the Institute the central figure of a fountain, which has this summer been unveiled on a West Side square known as Independence Square. An electric fountain in commemoration of Independence Day, it is somewhat of a shock to our preconceived ideas of what that or any other fountain, in fact, should be, with the traditions strong upon us of nude Goddesses of Liberty, swimming across the basin to crown with laurel wreaths equally nude Revolutionary generals, etc. This realistic treatment of a realistic subject is not without its charm however.

A real, genuine American "kid," the kind who gets up at three o'clock Fourth of July morning to make himself popular in the neighborhood, waves the Stars and Stripes above a sympathetic group, two girls and a boy holding aloft Roman candles. To further heighten the realistic effect and further shock artistic traditions, it has been arranged by some ingenious electrical device that red, white and blue lights shall appear at the ends of the Roman candles, and elsewhere over the group. Well, why shouldn't they? The Greeks painted the eyeballs of their goddesses. This is one of the first works passed upon and approved by the Municipal Art Committee, at this time consisting of Mr. Ralph Clarkson, artist, Mr. Leorado Taft, sculptor, Mr. Charles Hutchinson, President of the Art Institute, and Mr. W. L. B. Jenny, architect. The sculptor, C. J. Mulligan, is a Chicago man, and the casting was also done here. Good as the actual group is, it seems a great pity that the pedestal and setting should have been done by our State Architect and have borne his unmistakable hall-mark of commonplaceness. The figures stand on the well-known attenuated drum form, which seems in some minds to have a patriotic significance. It is dotted round with stars here and there and is entirely without strength or grace in design. It is altogether poor in design, and is a striking example of that combination before alluded to where the pedestal injures the effect of the work of the sculptor.

Several buildings of a public character are either in the first stages in the process of erection or are on the boards, ready at short notice to become realities. Noticeable among such work is the Thomas B. Blackstone Memorial Branch of the Chicago Public Library, 49th Street and Washington Avenue, and the Iroquois Theatre, to be erected on Randolph Street. The Library, which will hold about forty thousand volumes, will cost in the neighborhood of two hundred thousand dollars. It is to be of granite, Classic in style, and surmounted with a dome. In the interior this dome is to form the central point for a series of decorative paintings, from the brush of Mr. Oliver D. Grover, one of our Chicago artists. Mr. S. S. Beman is the architect of the building. Judging from the drawings, the building is dignified and good in proportion and outline.

Before the drawings of the Iroquois Theatre one pauses aghast. Perhaps it would be well to suspend judgment till the actual building can be seen. The façade suggests a titantic struggle for mastery between severe Classic and Rococo, both of the contending parties putting in as loud a claim as possible. This combat in glazed terra-cotta and iron, for these are the materials to be used, is described by an enthusiastic critic (?) as resembling in many points the Illinois Theatre, from the same architect's office, and, like it, being a "structure greatly admired for its classic repose." He further says, "In order to meet the spirit of the times half way, the architect has planned a façade in the modern French style, with some composite decoration to give it freedom and a quasi-original character. The base of polished granite is surmounted by columns and an elaborate front of glazed terra-cotta ornamented in the triangle of the roof with a huge escutcheon upon which is carved in heroic size the bust of an Iroquois Indian." It sounds a bit like a joke — Classic repose, modern French, and an American Indian on an escutcheon in the roof's triangle, alias pediment. That the theatre will be well equipped from a professional standpoint is, doubtless, true; that it

will afford ample comfort to its patrons is also equally true; but that it will be a work of art Chicago may well be proud of is as equally untrue, if one may judge from what is given to the public at present. The papers alluded to are already beginning to applaud it, and the public will, doubtless, follow suit, as they did in the case of the Illinois Theatre, by the same architect. It is discouraging to see, when it comes to critical architectural taste, how little discrimination the even fairly-educated man or woman has. The designs for the Iroquois Theatre are simply uncouth and of poor proportions, and yet we are told with enthusiasm that the architect "has been given *carte blanche* to provide the finest building for theatrical purposes that skill and money can secure."

One most interesting spot is where the problem of the mammoth foundations for the First National Bank Building is being worked out. Piles, concrete and steel no longer solve the question, but wells are being dug down to bed-rock, and these filled with concrete make the rock of ages on which will stand the First National. The work of excavating the wells is being done by miners, which would seem to be somewhat of a merciful dispensation in this time of coal-strikes. Work goes on through the entire twenty-four hours, three gangs of men interchanging with each other.

Just at present the inefficiency of the city Building-department is being shown up by a committee appointed by the Council for investigation. Building Commissioner Kiolbassa and his fifteen subordinates are being placed on the rack. Among other discoveries the committee found that there were eleven hospitals in Chicago for which permits had never been granted as hospitals. Apparently, no records worthy the name had been kept in the department, and on investigating the charge that the subordinates were too overworked to give proper attention to such things, it was found that on one day one of these overworked men visited two buildings close together and that on other days he did not visit any.

Just at present our aldermen seem to be in a very pugnacious state. The station-platforms of the elevated roads are much decorated with bill-boards. The corporation counsel has discovered that the city ordinances are being violated and a raid has been made on the posters by Alderman Frank Race, assisted by a gang of workmen. It is comforting to find that occasionally some one is stopped in his mad career of violating some municipal law in our poorly governed city.

PRUSSIAN BILL-POSTING REGULATIONS.

THE following account of a recent Prussian act concerning bill-posting in the country districts has been communicated to the London *Times* by Mr. Richardson Evans, Hon. Secretary, Society for Checking the Abuses of Public Advertising: —

"I desire, by your permission, to offer some account of a stimulating example lately set in Germany. An act to prevent the defacement of scenery was passed in the last session of the Prussian Landtag. It runs as follows: —

"'With the object of preventing the disfigurement of places remarkable for their natural beauty, the police authorities are empowered to prohibit outside of towns (*ausserhalb der geschlossenen Ortschaften*) such advertising boards or notices or pictorial devices as disfigure the landscape, by means of police-regulations issued in accordance with the law of July 30, 1883. Such regulations may apply to particular areas or spots.'

"Instructions, we are glad to learn, have now been issued by the central Government to the local authorities for the strict enforcement of the provisions of this salutary measure, and it may be expected that many painfully familiar eyesores on the frequented routes will speedily disappear.

"There is beauty worth saving in the street as well as on the river or among the mountains. But it appears from the proceedings in the Landtag that regulations already exist which are considered adequate for the protection of urban areas. As regards the open country, the Prussian Legislature has gone upon the lines which we are anxious to see adopted in English practice.

"1. The law is elastic; it places an effective remedy within reach where a grievance exists, but avoids any interference with general usage in the matter of business-notices.

"2. It sets up no arbitrary distinction between one class of conspicuous signs and another. The sole criterion is disfiguring effect. There is one and the same rule for the big letters on the wall of a building which announces that it is Messrs. So and So's manufactory and for the multitudinous puffs which the same firm sets up along all the highways of travel.

"3. The ground of public policy upon which we rely was asserted throughout the debate in strenuous terms. In the report of the committee which submitted the project occurs this paragraph: —

"'What is needed is the creation of a legal basis. We must do for the country what is already recognized as right for the town. The equitable interest of all who love beautiful nature is in question — that is to say, of most persons, whatever their nationality may be, who travel for pleasure. Nor can we overlook the pecuniary loss that will accrue if the progress of disfigurement diminishes the profits from the tourist traffic.'

"In the final debate in the Upper House, Herr Spiritus, the reporter of the committee, developed more fully the doctrine of the higher utility: —

"'We of the Rhine districts see many hundred of thousands coming every summer from far and near to seek on the sunny heights, wooded hills, and shady valleys rest and delight. All return strengthened and entranced. . . . It is the same elsewhere. I trust that the conviction will grow that it is the sacred duty of our generation, especially of our public men, to preserve for posterity these beautiful tracts of the Fatherland.'

"Let me add that the assent of the Diet was by no means perfunctory. All the stock objections, the claim for compensation, for exemption in favor of this or that order of advertising-sign, were urged and decisively rejected. The Hessian Legislature has included provisions of a similar character in a statute enacted recently for the protection of public monuments.

"Such is the way in which the wise and eminently practical people of whose progress so much is said among us order their affairs."

THE LAST RESTING-PLACE OF THE ANGEVIN KINGS.[1]

EVERY student of history who has wandered through the solemn choir of Westminster and the wonderful chapel beyond it has remarked how incomplete is the series of royal tombs which they contain. Of the missing sovereigns the greater number sleep in places sufficiently familiar to most of us — Winchester, Faversham, Reading, Worcester, Gloucester, Canterbury, Leicester, Windsor, Frogmore — but a few, including some of those whose names have thrilled the historic imagination the most strongly, have found their last resting-place in foreign ground. To visit every tomb abroad which is associated with English royalty would, indeed, be an extensive journey. It would take the reader, for instance, to Hanover, as well as to St. Germain, to Rouen, to Caen, and to the basin of the Loire. The present paper, however, is concerned only with the district last mentioned.

Save that it is in France, the position of Fontevrault upon the map is not perhaps very definitely known to most people. It will be found, then, on the southern border of Anjou, in the Department of Maine-et-Loire, and about nine miles south-east of the town of Saumur; and the present writer and a friend, finding themselves recently in that part of the Loire country, determined to make a pilgrimage to a spot which had always loomed in their minds, though in a somewhat shadowy manner, as a shrine of English history. The start was made from Saumur on a fine morning in September, and for the first few miles the route lay eastwards along the left bank of the Loire; but at Montsoreau, not far short of the point where the Loire receives the Vienne, a road branched off toward the south, ascending gently through orchards along the west side of a small valley. A very short ride from Montsoreau brought the object of the journey in sight. Straight ahead stood the little gray town of Fontevrault, and to the left, a few yards down the slope, rose the long slate roof of the Abbey church, with two turrets capped by spires at the west end, and over the crossing a tower having two pointed windows in each face and a slate-covered superstructure crowned by a pyramidal slate roof. In a land where central towers are not common such a sky-line had about it a strange and appropriate reminiscence of England. To the left of the Abbey the ground sloped more sharply down to the bottom of the dip, of which the farther side was clad with woods.

Fontevrault is dismissed by "*Baedeker*" in a dozen lines, yet it must have been a place of great interest, apart even from its principal building; for the Abbey was once surrounded by a number of dependent priories and other institutions which formed with it a considerable town. Of these buildings there are said to be still some remains;[2] but on the present occasion time forbade to do more than wander through an old church which had a wooden colonnade against it and contained two mediæval oil-paintings, and admire for a few moments the grace with which a party of soldiers at drill outside were wielding long ashen switches that did duty for swords.

How to get into the Abbey itself it took some time to discover, for in the high wall that surrounded it no open door gave a glimpse of the life within. But at last a peal of the bell at a great gate facing the main street had the desired effect. A key grated in the lock and the door swung ponderously open, disclosing, not the picturesque apparition of monk or nun, but the neat uniform of a prison warder! For the once splendid Abbey of Frontevrault, like many other religious houses, was suppressed at the Great Revolution, and in 1804 was actually degraded to a house of correction! Admission, consequently, is granted to the church and its immediate precincts only, and involves certain rather irritating formalities. The visitor is taken first into a porter's lodge, where he incribes his name, occupation, abode, and other particulars in a book, which is then sent over for the inspection of the *Directeur*. His admission being authorized by that officer, he is next conducted across the quadrangle and handed over to a second warder, who takes him into a rather narrower court and there introduces him to a third. So far there has been little to arouse his archæological interest. The white buildings around, from whose windows the inmates, clad in white canvas, peer curiously at him, are plainly modern, and the uniform of the Republic upon the warders, and upon the sentries in the second court, proclaims even

[1] Extracts from a paper in the *Nineteenth Century* for August, 1902, by Cecil Hallett.

[2] The surroundings of the Abbey include a curious mortuary chapel of St. Catherine, dating from the first half of the thirteenth century, and described by De Caumont as square, with a pyramidal roof crowned by a tall octagonal hollow shaft ending in an open lantern.

more frankly the abolition of the old order. In crossing the second court, however, he does catch a glimpse of a very singular building on the right, a sort of low tower with a steep conical stone-roof crowned by an open lantern. This remarkable structure, which is misnamed the "Tour d'Evraud" and recalls similar erections at Stanton Harcourt and Glastonbury in our own country, dates from the twelfth century and was undoubtedly the Abbey kitchen.

Meanwhile a third warder has unlocked a door at the farther side of the court, thereby revealing a winding flight of steps, on descending which the visitor finds himself in a great cloistered quadrangle, its court gravelled and planted with rows of small trees, with benches between. The cloisters, which have rooms over them, are externally Renaissance, but have Gothic vaulting, which, however, shows abundant signs of decadence. Round this court the buildings were arranged after the manner usual in the Benedictine Order. To the south they placed the refectory and offices; to the west the residence of the abbess; to the north the nave of the church; to the east the dormitory — a refined example of the early Renaissance — and below it the calefactory, the scriptorium, and the chapter-house.

The last-mentioned room — the only part of the domestic buildings to which visitors seem to be admitted — is entered through an elaborate Renaissance-Gothic doorway in the east cloister. Built perhaps in the twelfth century and remodelled in the sixteenth, it is a large oblong room with Renaissance windows and a soaring Gothic vault supported on two Renaissance pillars in the middle; and its walls are adorned with Renaissance frescos of the Passion.

From the north cloister a small door admits to the church. Here the visitor is at once met by a keen disappointment. The nave, whose exterior promises so much, has actually been walled off and converted to secular purposes; indeed it is described in 1851 as divided into three floors, with a mess-room in the lowest, cells in the second, and a dormitory in the third, with attics above! How interesting a specimen of early twelfth-century architecture is thus lost to the public (to say nothing of the dishonor done to the consecrated building) may be gathered from Verneilh's "*L'Architecture Byzantine en France*" (Paris, 1851). The choir and transepts have been retained as a chapel for the prisoners, whose rude wooden benches occupy most of the floor even in the eastern arm, and are so set that they all face the altar, which now stands under the central tower. The eastern half of the church is later than the nave, though both date from the twelfth century. The great apse in which the choir terminates is more lightly conceived than is usual in Romanesque architecture. Its numerous arches, narrow and "stilted," are supported on cylindrical pillars of a height and slenderness almost too marked, perhaps, for just proportion. But to English visitors the general architecture of the place, however worthy of attention, will be but a background or a setting to a certain small chapel opening out from the east side of the south transept, where the light falls through the windows of an apse upon four stately figures that sleep side by side behind an iron grille, with their feet towards the west. They are royally robed and crowned, and bear traces of a once gorgeous coloring, and at their feet, in modern characters and in the following order from north to south, are written their names: Eleanor of Guienne (to us better known as Eleanor of Aquitaine), Queen of England, wife of Henry II; Henry II, King of England; Richard, called Cœur de Lion, King of England; Isabella of Angoulême, Queen of England, wife of John "Sans Terre." . . .

The Angevin Kings, it will be remembered, were essentially continental potentates. Their dominions in western France extended from the Channel to the Pyrenees, and to them — even to Henry II — England was little more than a source of revenue — of revenue that could be spent upon their ambitions abroad. That they should have been buried in French soil, and especially in Anjou, of which province they were the hereditary Counts, is therefore not surprising. . . .

In 1793 the Abbey, like so many others at the same period, was suppressed. The process was gradual and the successive incidents need not be related here. Its climax was reached, perhaps, when the Revolutionaries, excited to frenzy by the peculiarly aristocratic character of this monastery, burst into the precincts with cudgels and axes and carried havoc into every corner — havoc which was announced to those without by cries of "The royal Abbey is fallen at last!" The church, of course, was the scene of wild violence, of which one of the principal objects was the great royal tomb. The kneeling statues of Raymond and Joan were broken up, and how the remaining four figures escaped it is indeed impossible to explain, unless they were saved by their more secluded position in the depth of the alcove. It is doubtful what became of the relics of the bodies — if indeed there were any. Some say they were scattered; some that they were scattered but afterwards collected and replaced. One story goes that afterwards, during certain operations in the church, a Mayor of Fontevrault found the remains of Richard and the heart of John; and further rumors have it that the latter was given to Monsignor (afterwards Cardinal?) Wiseman, who was then staying in the neighborhood, and that the former were sent to London. The antiquary M. Develle, however, on questioning a mason who had assisted in opening Richard's tomb in 1793, was told that not so much as a bone had been discovered. . . .

The late Charles Alfred Stothard, being then engaged upon his "*Monumental Effigies of Great Britain*," had come to Fontevrault for the express purpose of finding the Plantagenet tombs and including them if possible in the scope of his work. It was believed at the time that they had been destroyed, and great must have been his delight at finding them. He did not, however, find them intact, as various chips and fragments were lying about the cellar, having been knocked off doubtless by the prisoners. One result of his visit may be seen in the wonderful drawings contained in the "*Monumental Effigies*." Another was the suggestion which he made that the English Government should procure the removal of the effigies to Westminster Abbey. . . .

Stothard's proposal did, however, serve to draw attention to the fact that the effigies were in a disgraceful condition, and in 1819, it is said, they were moved into the Abbey church and placed, apparently, in the same part of it which they occupy at present. The English Government is reported to have renewed its request about this time, but with no better result than before. The position of the effigies, indeed, was still far from satisfactory. It is true that they were once more in the church, but they were thrust into an obscure corner of it and are said to have been treated with anything but respect by the tourists, who used them as benches; Montalembert expressly stating that they were in a bad condition when he visited them in 1831. Whether it was for reasons of this kind, or whether the explanation lies in the hold which Stothard's proposal had gained over the English mind, the removal of the Angevin sovereigns to Westminster was mooted again some time after the Revolution of 1830. But Louis-Philippe was no more able to comply than the Bourbons had been. . . .

It is said that in 1866 an English tourist, on returning from a visit to the Loire country, wrote to the *Pall Mall Gazette* and naïvely suggested, as if it were something new and original, that a presentation of the royal effigies to England by the Emperor Napoleon III would be a gracious act. His words, which are said to have found their way into *L'Univers Illustré*, were very possibly noticed in influential quarters. At any rate, their appearance was not mistimed, for it would seem that our Foreign Office had not allowed its oft-repeated demand to be forgotton, while at this moment Paris was full of her Exhibition at the Champ de Mars, the success of which would at least not be hindered by anything tending to strengthen friendly relations with England. Whether in consequence of these considerations or, as it is more pleasant to think, from a *sentiment de haute courtoisie*, the Emperor did actually offer the royal effigies to Queen Victoria. But the opposition to their removal showed itself more strongly than ever before. When the order came down from the French Secretary of State, the official whose duty it was to deliver them up refused to do so.

The Emperor had indeed exceeded his legitimate powers. The principle expressed in Article 525 of the *Code Napoléon*, that statues are fixtures if they occupy niches specially constructed to hold them, had been subsequently extended to statues on pedestals or otherwise, provided that there was evidence of an original intention that such statues should remain in position forever. Such evidence, of course, could not be wanting in the case of tombs; but even apart from this the *status* of fixtures which they had admittedly enjoyed before the Great Revolution had not been abrogated by any legal act, so that clearly they could not be alienated without the consent of the Legislature; while even if they had not been technically fixtures, no legislative act could have alienated works of art that had always been, in a sense, appanages of the French Crown, and that were also protected under the principles of *Droit Civil*. The opposition offered to their removal by the Society of Agriculture, Science, and Art of the Department of Maine-et-Loire, who petitioned the Ministry, was supported by the gentry throughout Anjou and by a feeling general in France, and the Emperor was compelled to write to the Queen and ask to be released from his promise. Needless to say, his request was granted, Her Majesty "not wishing that affront should be offered in her name to the pious and patriotic wishes of the kings, her illustrious predecessors of the house of Anjou." . . .

The royal effigies are better cared for to-day than at any time since the suppression of the Abbey. They may not even be photographed without previous application to the *Directeur* of the prison (a restriction prompted, however, less by love of Kings than by fear of cameras). They are protected in the more material sense from prisoners and tourists alike by an iron grille of uncompromising severity. Yet it is difficult to rest content even with their present condition, unless one belongs to that school of æsthetics which refuses to scrape whitewash off a fresco on the ground that, though the whitewash obliterates the fresco, to scrape it off would be to obliterate a phase in the history of bad taste. Their carved biers now rest upon the pavement; but imagination flies back to the time when they were elevated upon altar-tombs. . . .

Queen Victoria, in releasing Napoleon III from his promise, added her request that the church of the royal Abbey might be restored to Catholic worship and the effigies of the English sovereigns replaced in that position in the building which they occupied for more than five centuries. It is strange that a wish, coming from such a source and addressed to such a destination, should not have been gratified at the time.

MONUMENT ERECTED BY THE SALESIAN FATHERS OVERLOOKING THE BAY OF RIO DI JANEIRO, BRAZIL.

"AMONG the festivities in honor of the nineteenth centenary of the nativity of Jesus Christ, it is necessary to mention especially the festivity of the 8th of December in 1900, in which the Salesian Fathers of Nictheroy, Brazil, had a large monument erected on the top of a high hill, joining the Colegio Santa Rosa. The exceptional importance of this festivity was not only of a religious character, but also a patriotic one, as it commemorated also the fourth centenary of the discovery of Brazil.

"About 100 metres above the level of the sea, on the hill on which is located the Colegio Santa Rosa is erected a high column, terminated by a beautiful statue of gilded bronze, representing a Maria Auxiliadora. The total height of the monument is 38 metres, 32 metres being the height of the column, and 6 metres the height of the statue. On the rock on which the monument is erected is engraved the sentence: "*In petra exaltasti me.*"

"The base of the column occupies a space about 60 metres square, each side being about 8 metres long and 10 metres high, constituting the first part of the monument. An elegant chapel is inclosed and occupies the interior part looking towards the east, dominating the district of Santa Rosa and Icaraby, the most beautiful part of Rio Janeiro, and from the immense bay beyond the wharf can be seen a statue of the Virgin, shining like the sun, when the day-star sends its rays on the beautiful face of the Mother of God.

"On the posterior side is a comfortable stairway of cast-iron, which leads to the upper part of the monument. The rest of the base of the monument is occupied by several tombs, within which the Salesian Fathers of Brazil will put the venerable remains of our lamented Mons. Lasagna and some of the other victims of the terrible disaster of Juiz de Fora.

"On this base, an immense mass of about 600 cubic metres, is raised the elegant column, 17 metres in height, which, from the second part of the monument, has on each side a small window with a small corresponding balcony, and on the part overlooking the sea is a symbolic star which is illuminated with electric-lights with the words: "*Ave Maris Stella.*" This column, which has from the foot of the base 25 square metres of surface, diminishes towards the top, which measures 3 metres on each side. Here ends the beautiful winding stair, which curves in the monument, and whence visitors see an enchanting spectacle. At the same time the more audacious come up by another exterior stair of 6 metres, to the foot of the statue.

"The plan of the monument has been traced by an able engineer, Sr. D. Domingo Delpiano, a Salesian, whose celebrated reputation as architect is founded on his work in Brazil and Uruguay. The eclectic style combines in agreeable harmony the Byzantine, Moorish and Pointed Arch. There has been employed for the construction more than 300,000 bricks and about ten months of arduous labor. The statue, of copper, was cast in the foundry of Luis Del-Bo, of Milan. The neighborhood of Santa Rosa furnished the entire electric system. At the foot of the statue are three electric-lights supported by three large candelabra weighing about 600 kilos each. They illuminate the body of the statue. Besides these, there are 12 electric-lamps affixed in 12 stars, composing the diadem surrounding the head of the Virgin."—*Boletin Salesiano.*

METAL-COVERED WOODEN FINISH.

BOSTON, MASS., September 23, 1902.

TO THE EDITORS OF THE AMERICAN ARCHITECT: —

Dear Sirs, — In re Fireproof Wood: In our report upon this subject what we had to do was to prove whether or not wood treated with chemicals had any right to the title of "fireproof." I recommended that wherever such wood should be used it should be encased in metal, giving preference to untreated wood because it is not liable to mould as much as so-called fireproof wood is.

In the same report we referred to the future test of substitutes for wood which can be moulded, framed and decorated in many ways and of which there are many kinds. That test waits the construction of a building or laboratory of sufficient size to put up the interior finish — doors, window-frames, dadoes and the like — in the same way in which they would be put up in any building.

It is singular to observe how strong the effect of habit is: some of the makers of doors and mouldings of metal and other substances seem to feel obliged to imitate a panelled wooden door of the ordinary type, as if a finer and much more artistic door might not be made of the materials which they use. In this imitation of wood in metal, they are governed partly by the instructions which owners give to architects rather than from the want of knowledge by architects of the decorative effects which may be given in metal without imitating wood.

Yours very truly, EDW. ATKINSON.

NOTES & CLIPPINGS

ACCIDENTAL ELECTRIC SHOCK. — The *Electrical World and Engineer* is the authority for the statement that accidental electric shocks seldom result in death unless the victim is left unaided too long, or efforts at resuscitation are stopped too early, as in the majority of instances the shock is sufficient only to suspend animation temporarily, owing to the momentary and imperfect contact of the conductors, and also on account of the resistance of the body submitted to the action of the current. The rules given to be observed and promptly executed with care and deliberation are as follows: —

"*Rule* 1. — Remove the body at once from the circuit by breaking contact with the conductors. This may be accomplished by using a dry stick of wood, which is a non-conductor, to roll the body over to one side, or to brush aside a wire, if that is conveying the current. When a stick is not at hand, any dry piece of clothing may be utilized to protect the hand in seizing the body of the victim, unless rubber gloves are convenient. If the body is in contact with the earth, the coat-tails of the victim, or any loose or detached piece of clothing, may be seized with impunity to draw it away from the conductor. When this has been accomplished, observe Rule 2. The object to be attained is to make the subject breathe, and if this can be accomplished and continued, he can be saved.

"*Rule* 2. — Turn the body upon the back, loosen the collar and clothing about the neck, roll up a coat and place it under the shoulders, so as to throw the head back, and then make efforts to establish respiration (in other words, make him breathe), just as would be done in case of drowning. To accomplish this, kneel at the subject's head, facing him, and seizing both arms draw them forcibly to their full lengh over the head, so as to bring them almost together above it, and hold them there for two or three seconds only. (This is to expand the chest and favor the entrance of air into the lungs.) Then carry the arms down to the sides and front of the chest, firmly compressing the chest walls, and expel the air from the lungs. Repeat this manœuvre at least sixteen times per minute. These efforts should be continued unremittingly for at least an hour, or until natural respiration is established.

"*Rule* 3. — At the same time that this is being done, some one should grasp the tongue of the subject with a handkerchief or piece of cloth to prevent it slipping, and draw it forcibly out when the arms are extended above the head, and allow it to recede when the chest is compressed. This manœuvre should likewise be repeated at least sixteen times per minute. This serves the double purpose of freeing the throat so as to permit air to enter the lungs, and also, by exciting a reflex irritation from forcible contact of the under part of the tongue against the lower teeth, frequently stimulates an involuntary effort at respiration. To secure the tongue if the teeth are clenched, force the jaws apart with a stick, a piece of wood, or the handle of a pocket-knife.

"*Rule* 4. — The dashing of cold water into the face will sometimes produce a gasp and start breathing, which should then be continued as directed above. If this is not successful the spine may be rubbed vigorously with a piece of ice. Alternate applications of heat or cold over the region of the heart will accomplish the same object in some instances. It is both useless and unwise to attempt to administer stimulants to the victim in the usual manner by pouring it down his throat."

"THE TRIUMPH OF NAPOLEON" IN THE LUXEMBOURG. — The Palace of the Luxembourg is one of the buildings which was associated with the triumphs of the first Napoleon. In 1797 the Directory gave him a reception in it when he returned to France with the treaty of Campo Formio. It was at the Luxembourg that he planned his *coup d'état* of the 18th Brumaire. In 1801 the building was used as the Palace of the Senate, and in 1806 fifty-four flags captured from the enemy were deposited there. Afterwards there was a fête and banquet, at which representatives of the Grande Armée were present. It was fitting that a commission should be given for an immense painting to be placed in the building, and which was to commemorate the "Triumph of Napoleon." The antique style was then in vogue, and Jean Baptiste Regnault, to whom the commission was accorded, showed the sovereign as a Roman emperor seated on a triumphal car, and surrounded by figures of "Victory," "Concord," "Peace" and "Wisdom." But in 1814 the power of Napoleon waned. The Controller of the Luxembourg was Semonville, and he lost no time in becoming a Royalist and in transforming the hall of the Senate in order that it might be worthy to receive Louis XVIII. All the symbols of Napoleonism were whitewashed or removed. From a large bust of the Emperor the head was taken off, and a label was placed on the part remaining to announce that it was a bust of Nero which was in the process of restoration. The immense picture of the "Triumph" could not be treated in the same way. Semonville was therefore compelled to give an order to a painter to substitute the face of the King for that of Napoleon. The Emperor, however, unexpectedly returned from Elba. Semonville fled, and the architect in charge of the palace had the visage of Napoleon restored. After the Hundred Days the King came back and Semonville was once more in power, but he had been taught to realize how insecure was sovereignty in France, and Regnault received £400 to paint out the figure of Napoleon and to substitute one of a woman typifying France. — *The Architect.*

PAPER BUILDINGS. — The *Paper-makers' Monthly Journal* reports that a Russian nobleman has upon his estate at Savinowka, in Podolia, a paper house of sixteen rooms, built in New York, at a cost of 80,000 roubles, and its architect declares that it will last longer than a stone building. Bergen, in Norway, has a church built of paper capable of seating a thousand people.

PHOTOGRAPHER VS. PAINTER. — "The New Photography" is the subject of two articles in the October *Century*, illustrated by examples of pictorial work with the camera. Alfred Stieglitz, founder of the Society of the Photo-Secessionists, gives account of the progress of the new movement here and abroad, and Alexander Black contributes a debate between a photographer and a painter, with a professor as umpire, on the burning question whether photography is an art. The following passage-at-arms presents one of the points of difference: "Look here," the painter exclaimed; "you don't suppose that I am insisting that only self-consciousness is intention. The thing I hold is this: that there is a vast, a final difference between the accidental personal expressions of a man and the accidental impersonal expressions of a machine. It seems to me, — with no disparagement of you, Mr. Photographer, — that if you stuck up a camera anywhere, and had it worked by clockwork long enough, you would occasionally, by some accidental combination of light, time, season, or incident, get as good a thing as a man could get by his added discernment. The beauty of these things being based on a natural reflection of nature, it is a question whether mere chance might not do more than personal interference." "My answer to that," retorted the photographer, "without expressing opinion as to the length of time you might have to wink the machine, is that if you were mechanically to spatter different colors of paint on a series of canvases, you would undoubtedly, in time, get an effect quite as expressive as some of the things you are willing to call art. It seems to me that whether or not both of these things are true, the fact remains that effects can be wrought, that things can be *said*, intentionally in photography. The fact that nature does some wonderful plastic feats hasn't hurt sculpture. In fact no art is or can be hurt by the circum stance that nature is more than a successful rival in the creation of forms. I don't see that the photographic accidents hurt the photographic intentions, and I think that when you have studied the expressions of recent photography you will not fail to find signs that photography, a science *per se*, is a medium of artistic expression, and that when it is so used, and in the degree in which it is so used, it is an art. In other words, I can't see for the life of me why the fact that photography has been a science shall forever stand in the way of its admission as an art."

MALLEABLE GLASS. — A description of tests upon the malleable glass now being manufactured in Matthews, Ind., is given as follows by the *Scientific American*: "A chimney was placed in a pail of ice-water, and after having remained a sufficient length of time to become as cold as the water, was taken out and immediately placed on a lamp with a blaze turned as high as possible. The blaze on the wick was turned so as to flow directly on the chimney, and the smoke which collected on the chimney ran down with the water without injuring the chimney. Next, a chimney was placed over a small gas-stove containing clay-bricks used in heating such stoves. The fire was turned on full, the chimney remaining on the bricks. The fire finally brought the temperature to such a stage that one side of the chimney was drawn in and dropped down, and no crack was shown in the glass; but for a slight roughness on the outside, the glass was as clear as when placed in the fire. Another test which was made was to place cold water in the chimney and hold the same over a fire until the water boiled. A large bulb was blown from the glass and filled with about one pint of water. It was then placed over the fire and allowed to remain there until it had boiled dry without apparent effect on the glass. Four chimneys were taken from the packing-room and dropped one by one into a pail of boiling water. The chimneys were then hastily shifted into a pail of cold water, that had just been drawn from a well, and the glass was not broken. A further test was made by nailing up a box containing glassware, every nail being driven in by hitting it with a chimney. The most remarkable feat of all was the making of a perfect lamp-chimney by using a chimney as a mould and blowing hot glass into the same. Both the new chimney and the mould came through the test perfectly whole, uncracked, and unscarred. In appearance this malleable glass is much like the common product; it is, if anything, a little clearer than the glass now in use, and in its molten state is much more elastic. It can be made of the thickness of a sheet of paper, or as heavy as any in use, but in every instance it is tough — a dainty table-glass could be handled as roughly as a skylight, and no harm result. The advantages conferred by this toughness in the wide variety of glass utensils for domestic use are very numerous."

RUSKIN'S ENGLISH. — A civil-service-academy journal recently gave a model exercise. The subject for essay was "Mountains and their Beauty," and a wily but suspicious reader copied out an essay in competition. He wrote it in the beautiful, stiff civil-service hand with all the letters joined in the middle; he punctuated it carefully, and made it, in every sense, a creditable production. He was awarded 41 per cent for English. He was told that his English was rather stiff, and that his descriptions were not lifelike, and were too "journalistic," whatever that may mean. Also, his sentences were too long and his ideas lacking in originality. It was a very sad reflection to think that it was an extract from Ruskin's "*Modern Painters*" on "Mountains and Mountain Beauty"! One candidate got 97 per cent, being twice as good as Ruskin apparently. — *Liverpool Post.*

OLDEST THRONE IN EUROPE. — According to the *Fronde* there is an older throne in Europe than the one on which the King was crowned, and that throne is in France. The throne belonged to King Dagobert, who reigned in the seventh century, and it is in the Cabinet des Médailles at the French National Library. Dagobert's throne, which is of brasswork, was forged and chiselled by Saint Eloi for King Dagobert, and 100 years ago was used for the last time in a public ceremonial — that of the distribution of the eagles by the first Napoleon.

NOTES AND CLIPPINGS. 7

"IT is, indeed, a valuable work, for the historian, scholar and reader of American literature as much as for the student of architecture."—When, in spite of the multitudes of complete new books which lay claim to its notice, the *Nation* finds it worth while to give serious consideration to each fragment of the "*Georgian Period*" as it appears and to express, in terms more or less similar to those which we quote above from its review of the Tenth Part, its appreciation of the manner in which we are accomplishing our undertaking, we feel more and more satisfied that those who have joined with us in the production of the work have just cause for gratulation that their names will be associated with the production of an acceptable fragment of architectural literature. For our own part, we hope that, in the fulness of time, our account-books may show that we had a commercial justification in expending the many thousands of dollars the work has cost us. But, though the general reader finds the work interesting, it was intended primarily for the architect, for those the bulk of whose work consists in the building of five or ten thousand dollar houses quite as much as for those to whom a hundred thousand dollar job is no rarity. It is emphatically a *useful* publication to architects and builders of every grade. This reference to the "*Georgian Period*" is in the nature of a "last call,' for the reason that on the publication of the Twelfth Part, which is now nearly ready for the press, the discount now prevailing will be discontinued. It would, therefore, seem to be only good business policy on the part of those whose sets are incomplete and those who intend eventually to procure the work to take advantage of the fleeting chance and send in their orders now.

THE great coal strike, or, rather, the great assault made upon the public in furtherance of a conspiracy between politicians and would-be union tyrants, is rapidly approaching the alarming stage. Although a small military force is in the anthracite region, it seems to be without efficiency or authority, for the strikers assault and kill men every day, and blow up houses with dynamite, apparently with impunity, the military appearing, in the newspapers, only as having been "stoned by the mob." The commanding officer seems to be disposed to act, but it is not easy to do much under instructions which oblige soldiers to submit in silence to "stoning," and which expose any one who uses his rifle or bayonet in self-defence to immediate arrest and incarceration on a charge of murder. Meanwhile, the supply of coal in the Eastern cities is being rapidly exhausted, and a few days of cold weather, which may be expected at any time now, would cause great suffering. Some large city schools have already been closed, on account of the impossibility of warming them; and the hospitals must follow, unless relief is soon given; while the poor people are already suffering. One poor laundress, within our knowledge, has already been obliged to send her customers word that she cannot take any more work, not having any means of heating water; and there will soon be many similar cases, followed, as winter approaches, by thousands of deaths from cold and privation.

IT is curious to see Mr. Mitchell, who could set the miners at work with one word, making the tour of the country, to ask the people whose distresses are due to him to contribute of their scanty means to support his plans for putting himself in control of the anthracite industry, especially after the exhibition which he is making of his devotion to the cause of the "toilers," by sending off, under his direction, as he claims, thousands of anthracite miners to the bituminous coal regions, to take the bread out of the mouths of the bituminous coal miners, who have been the most generous contributors to the anthracite strike fund. In the meantime, the clamor of the Republican newspapers for some grand stroke on the part of President Roosevelt, or his administration, in seizing the mines, "compelling arbitration," or some other unconstitutional abuse of power, is taken, whether rightly or wrongly, by a large part of the community as an indication of collusion between the strike leaders and, perhaps, the coal operators, and influential Republican politicians. Naturally, the Democratic election committees are preparing to take advantage of this feeling at the November election, and it is doubtful whether the country would not, in the end, be benefited by a severe rebuke at the polls to a party incapable of defending citizens in the peaceful exercise of their employment, and responsible for such an act of oppression as the Pennsylvania miners' license law.

SO far as New England and New York are concerned, it is strange that relief should not be sought from the anthracite mines which underlie a great extent of territory in Massachusetts and Rhode Island. For nearly a hundred years, anthracite, of a very hard quality, but quite available for purposes to which the Lehigh coal is adapted, has been mined in a small way near Tiverton, Rhode Island, and used in the neighborhood. So long as the Pennsylvania anthracite could be obtained at a reasonable price, it was preferred; but, that supply being cut off, it seems as if the Tiverton beds, which contain an enormous body of coal, might be utilized. In case of need, it would be quite within the powers of the States of Massachusetts and Rhode Island to seize the mines and operate them, just as Governor Hoffman, in New York, thirty years ago, seized the Hudson River Railroad, on the occasion of a strike of trainmen, and operated it under martial law; and such a precedent would be far less dangerous than the interference of the Federal Government in such affairs, or than Constitutional amendments in favor of "compulsory arbitration."

FEW things have been more satisfactory to watch than the developments that have attended the reorganization of the office of the Supervising Architect of the Treasury Department, begun by Mr. Aiken and carried by Mr. Taylor to a higher level than any one thought could be possible. When the Tarsney Act was to be accorded a trial, it was, in the ranks of the profession, rather taken for granted that the designs prepared in the offices of private practitioners, selected with care and discrimination, would by their superior merit greatly overshadow the designs prepared under the eye of the Government's official architect. But, without in any way detracting from the merit of the designs prepared under the Tarsney Act, we feel that architects generally will agree that the average architectural worth of the designs for which Mr. Taylor is officially responsible has at least equalled the average worth of those prepared by private architects, under the workings of the Tarsney Act. That as little as this can be safely said shows in itself how great a change has been accomplished and how grateful the profession, and the public at large, should be to the man who has had the good sense, the patience and enough self-abnegation to bring about the long-desired improvement. Mr. Taylor recognized that, no matter how much the routine methods might be changed and bettered, good results could not follow unless the work of all kinds could be handled by

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.

Entered at the Post-Office at Boston as second-class matter

designers and draughtsmen as competent, well-trained and reliable as those who held permanent places in the best private offices, and one of his first cares was to replace incompetent political material with trained architectural ability. In this he gradually succeeded, and the throwing the protection of the Civil Service law over the members of the working force has helped him to secure a grade of assistants that would hardly have been possible without it. The consequence is that the personnel of the office is of an unusually good type and the place has acquired the real atmosphere of an architectural studio, to have access to which a young man may now honorably be eager. Ten years ago it would never have occurred to us to recommend an able young man to secure a position in the Supervising Architect's office; it would have been simply to advise his voluntarily seeking to degrade his own talent and set a bar across the path of his professional progress. Happily, things are changed, and we can now not only advise but urge young men of ability, who have not the connection and backing that entitle them to believe they can become successful private practitioners, to seek a position in the Government office.

WE speak of the matter because, just now, the office is in need of a score or so of competent young men, and as the Civil Service Commission is to hold an examination for the establishment of an eligible list towards the end of October, we believe it is well worth the while of draughtsmen of real ability to take the time to pass these examinations and secure a place on the list, as a kind of "anchor to windward," even if they have no immediate desire to become public servants. The places to be filled yield salaries of from eight hundred and forty dollars to twelve hundred dollars per year, with chance for promotion and increase of pay up to twenty-two hundred dollars per annum. The hours are short, from nine to four o'clock daily, the year through, but with generally a chance for leave of absence for thirty days, on full pay, at some convenient time. The hours and the pay are attractive — they always were that, at least — but what now makes it worth while to pass the examination is the chance of securing the *entrée* to a thoroughly well organized office, where a vast amount of interesting work is done, and to the agreeable companionship of a group of highly-trained and capable associates. A very large number of public buildings was authorized at the last session of Congress and further bills will be introduced at the next session, so that there is little likelihood that the office force will be curtailed by compulsory discharges for several years to come, and as we have every reason to believe that Mr. Taylor has so firmly established the fact that he is the right man for the place that there is little likelihood that he will not be reappointed at the end of his official term, there seems to be good grounds for believing that the tone of the office will long remain as agreeable as it is now and the work produced there as instructively interesting.

THE Wholesale Grocery Employés' Union of Chicago has set the example of voluntary application for a charter of incorporation, under the laws of Illinois. This step is taken as a preliminary to the making of contracts between the union, as a body, and the employers, which the members of the union believe can be made to better advantage if the union treats as a responsible corporation, liable in damages for any breach of its agreements. While we believe that the separation of employers and employed into different, and, to some extent hostile, organizations is a misfortune for both, depriving the employer of the intelligent and sympathetic coöperation of his assistants which is so advantageous for both, at the same time that it degrades and discourages the persons employed, by separating them from those who can appreciate and reward faithfulness and intelligence, and tying them to those whose interest it is to repress industry and ambition, it is, at least, a step in advance to give the unions a character of responsibility and integrity, instead of making them nurseries of dishonesty and shiftlessness. A workingman who finds that his union maintains its agreements to the letter has received a lesson of incalculable value, not only to himself, but to the community of which he forms a part; and the spread of honesty and fidelity in the community, if it can be secured by such means, may have momentous results.

AUSTRALIA has been so long famous as the trades-union paradise that it is only fair to draw attention to the occasional notes of discord which mar the general harmony of its affairs, and to point out the possibilities of future trouble which these indicate. As every one knows, the eight-hour day, that highest good of every one who does not care to distinguish himself in this world, and does not wish any one else to do so, has for several years been established by law throughout the country. In addition to this, the unions hold complete political control, and their differences with any employers who have the temerity to resist their dictation are settled, under compulsion, by courts of arbitration, which have, until lately, practically given their decisions invariably in favor of the union men. In addition to these delights, the unions, in order to keep their members constantly employed, at high wages, have utilized their political ascendency to run the colonies, or, more properly, the taxpayers of the colonies, into debt at a frightful rate, using the money raised by the sale of bonds for public works of all kinds. When the indebtedness of the colonies reached something like a thousand dollars for each family, or about ten times the proportion of debt to population which prevails in the United States, the credulity, even of British investors, took alarm, and public works came to an end, for want of anybody simple enough to lend money for them. Then the unions, finding employment slacken, made a characteristic move. Reasoning that, if there was not work enough to keep them all employed at satisfactory wages, the remedy for the trouble was to prevent any one else from coming to take away such jobs as might be left, they passed laws, in most of the colonies, forbidding immigration. This measure, which simply strangled the natural growth of the country, did not bring much relief to their troubles, and even the courts of arbitration became so unruly as to decide occasionally against the demands of union workmen upon their employers. As the conviction dawned upon the more sensible people in the community that public bankruptcy was staring them in the face, some feeble attempt was made to postpone the crash by reducing the public expenses, so as to save money to pay the interest on the bonds. A large proportion of the voters have comfortable positions on the various public railroads, and it was thought that these could bear a slight reduction of their salaries for the common good, particularly as the operation of the railways, which were purposely built of different gauges, so as to prevent interchange of cars, and possible economies in administration and management, is extravagantly expensive. The railway hands, however, who found their berths extremely satisfactory, and knew their political power, struck against the reduction. The other union men made common cause with them, and, in one of the Australian States, the economical Ministry has already been ignominiously driven from power. What will be the conclusion of the comedy remains to be seen. It is evident that, with Australia shut off from immigration, and loaded with an overwhelming debt, there can hardly be any alternative between economy and repudiation, and the ruling class seems determined to reject the former.

PROFESSOR ARTEMIEFF, of the Technical High School in Kieff, Russia, has invented a protection against high-tension electricity which deserves to be widely known, although it was originally devised only for the benefit of Professor Artemieff's assistants in the electrical laboratory of the School. The protective armor consists simply of a dress of very fine brass wire-gauze, covering the whole body, including the hands, feet and head. The whole affair weighs only a little over three pounds, but it seems to afford complete protection, a current of any tension, and any ordinary volume, being carried off by the metal before it can reach the body. Even in the case of very heavy currents, which might be expected to heat the wire to an uncomfortable degree, the surface of metal exposed to the air is so large that the temperature is only slightly raised. In experimenting with the armor before a scientific Commission, of which he was a member, Professor Artemieff, clothed in the wire cloth, and standing on the ground, drew sparks from a wire charged with current at seventy-five thousand volts, ending by grasping the wire. The pressure of the current was then raised to one hundred and fifty thousand volts; and, as before, the experimenter drew sparks from both poles, and held both wires in his hands. In these experiments the current was derived from a transformer, supplied by a direct-current machine of one hundred and seventy kilowatts capacity. Professor Artemieff then put his hands on the electrodes of the machine, short-circuiting through his arms a current of two hundred ampères, at one thousand volts pressure. In all these trials he was perfectly protected by the wire-gauze, feeling, as he said, no effect whatever from the current.

ITALIAN TOWN-HALLS OF THE MIDDLE AGES.

COMMUNAL life has been particularly fruitful in Italy. The liberties of the communes brought to the Peninsula abundant riches, hence the period of the Middle Ages formed an epoch of active industries with us, and although time has destroyed a large quantity of the monuments everywhere, there still exist witnesses to this communal life which has been one of the popular and democratic glories of the Italian character.

The public palaces, or town-halls, are the most notable examples, and in point-of-view of monumental importance need not yield the palm to the great cathedrals. We must take a glance at this group of monuments, selecting the most important. Tuscany is exceptionally rich in them, and we will begin with this territory, which was the birthplace of Dante, Machiavelli and Michael Angelo.

In Florence, the Bargello, at present the National Museum, first draws our attention. It was the Palace of the Podestà, that is, of the highest municipal authority, who happened also to be the highest political authority. Imposing, crowned with crenellations, it was begun about 1250, and its aspect, so far as strength and dignity go, is entirely suitable for the residence of the chief man of the city. The original design has been attributed to an architect named Lapo, a fellow-pupil with Arnolfo di Cambio, the first architect of the Cathedral of Florence; but it is certain that the palace was modified in the course of the work and that popular outbreaks, conflagrations and inundations operated in such a way that the palace as we see it to-day is very far from being the one designed by Lapo, if Lapo really was its first architect, his place being taken in later times by Benci di Cione and Neri di Fioravante.

On one of the façades, near the door, about 1288, they used to paint the effigies of traitors who had contumaciously objected

Courtyard of the Bargello, Florence.

to come in and be actually hung *in corpore vili*. Amongst those who underwent this platonic punishment were the Duke of Athens and his most faithful adherents. The architectural irregularities of the façades find their correspondences in the courtyard, which is one of the most picturesque bits of architecture to be found, whether because of the majestic value of its lines or because of its coloration. The stairway, guarded by "Il Marzocco," and its rich armorial decorations are known to everybody.

The celebrity of the Bargello has not eclipsed that of the Palazzo Vecchio, which, during the time of the Florentine Republic, was at once the fortress and the official home of the Government, and was called the Palazzo del Popolo, Palazzo della Signoria and Palazzo dei Priori, because the Priori delle Arti, with their Gonfaloniere della Giustizia, constituted the executive power in the democratic organization of the Commune.

This imposing palace was begun in 1299 after the designs of Arnolfo di Cambio, who, as they say, took for his model the then recently built castle of the Counts Poppi, in Casentino, Tuscany. It was finished in all essentials in about 1314; at that time it was a lofty and crenellated quadrilateral tower-surmounted building of which nowadays we see only the two sides at the angle of the piazza and the third on the Via della Ninna, with eight windows on the north, six on the west and four on the south, with two doors on the west and north. It was only in 1308 that was begun the tower which is picturesquely placed a little to one side of the centre, for, as the story goes, they wished to make use of the old tower of the Palazzo Foraboschi, surnamed "de la Vacca." This tower is the most elegant portion of the Palazzo Vecchio, the most celebrated of the communal palaces of Italy, after the Ducal Palace at Venice.

There is no use in halting to examine the exterior, but the court and the halls should be seen, although the visit cannot be made in a moment; but I must restrain myself, and simply draw attention to the celebrated hall called the Sala dei Cinquecento, which is one of the most imposing and successful architectural and decorative compositions to be found in all Italy. Built for the Grand Council of the people in consequence of the demands of Girolamo Savonarola, the reformer frequently preached in it. Moreover, this hall of the Cinquecento was to be decorated by Leonardo and Michael Angelo, those two immortal masters who, in fact, did some work on it in 1504. Leonardo was to paint the Battle of Anghiari, and Michael Angelo the Battle of Cascina, but neither the cartoons nor the works themselves nor the beginnings of the frescos have remained for us. There is only the description given by Vasari, a writer and artist of the sixteenth century, who, entrusted with the general renovation of the Palazzo Vecchio, with the aid of several artists, left it a very treasury of the imagination.

More elegant than the Palazzo Vecchio, although less characteristic, is the Palazzo Or San Michele, also in Florence, at once a church and a palace, which externally is rather a palace than a church or oratory. A loggia forms the beginning of this edifice, and this loggia was built, about 1337, on the foundations of a still older one, erected for the grain-trade in 1280. It is not certainly known who was the architect of the new building, and it is likely that it was Taddeo Gaddi, but I believe that the famous Francesco Talenti, who, being the architect of the Cathedral of Florence and of the campanile now known as Giotto's Campanile, enjoying at that time a great name, had some part in rebuilding this structure, with its fine mouldings and its cornice supported on consoles — a magnificent crowning and one wholly proper to a Florentine monument. However this may be, Or San Michele bears witness to a feeling for monumental effect which the Florentines of those times possessed. It is not in fact, however, a communal palace, but it has all the air of being one, and because of this I mention it here.

A building still more clearly stamped as a communal palace is that at Pistoja, near Florence, and I know nowhere in Italy a palace more grave, more massive, more serious than this one. Begun in 1294, by the Podestà Giano della Bella, it was finished about 1353 in a pointed style which has none of the elegance proper to that style. The exceptional gravity of this palace may have been corrected by a polychromatic decoration, of which the late G. Gailhabaud, after documents which were furnished him by a French architect, the late M. Laval, presented the model in his monumental publication, "*L'Architecture du V au XVIII Siècle.*" The Palazzo del Comune at Pistoja, according to this restoration, originally had its windows decorated with painted leafage and its walls worked *en bossage* separated by red lines, and if this decoration really existed it is certainly an important example of polychromy applied to architecture. But all this is a dream. M. Laval made one of the most deplorable mistakes that an architect travelling in search of documents to publish has ever made. I can assure him, for I have made researches in this connection, having studied long ago the restoration of the Palace at Pistoja, that my researches justify me in saying that the illustration inserted in the work of the above-mentioned French author is nothing but a solemn farce.

Since one often takes pleasure in contrasts, I beg you to consider, side by side with the Palazzo del Comune at Pistoja, that at Siena, "the red city," as M. Bourget calls it. This city, entirely filled with Gothic buildings of the fourteenth century, so full that no city in the north or centre of Italy — Florence or Venice, or even, in foreign lands, Bruges or Nuremburg — is richer in this respect, this city possesses the most elegant communal palace in the entire Peninsula, and its slender tower, which makes one think of the most sky-piercing minarets of the Orient, this tower of brick and stone, could not be more light and poetical; surely, it is one of the finest of its class in all Italy. But the building itself, which rises on the Piazza del Campo at Siena, has an *ensemble* of a marked and picturesque character; a character due in part to the details, the doors and windows, the greater part of the latter separated by colonnettes. One must notice in the Sienese pointed arch that its function is merely decorative; there is often below it a discharging-arch, usually segmental, which gives to the Gothic system of Siena, and only of Siena, a *cachet* which is altogether individual.

Just as I have said in the case of the Palazzo Vecchio at Florence, I will say here, that the courtyard (in process of restoration at present) and the halls, likewise, have an interest of the highest order for artists and visitors careful to inform themselves as to the whereabouts of the beautiful things in Italy. The halls of the Palazzo Pubblico at Siena constitute a veritable museum where frescos by the most eminent painters of the Sienese school are intermingled with works in wrought-iron and carved furniture. The frescos in particular cannot catch the eye of the visitor without his acquiring a very distinct impression.

The Palazzo Pubblico of which we are speaking is the most important and majestic of a group of Sienese palaces, private monuments in stone and brick; as, for instance, the Palazzi Salimbeni, Buonsignori, Tolomei, Saracini, and so on, which have rather the air of fortresses than of private habitations, and maintain a rivalry with the public buildings of the time.

The architecture of these palaces is of the purest simplicity and modesty, exteriorly, while within, on the contrary, everything was luxurious. I say "was," for the interiors of these seigneurial habitations have been everywhere defaced. Italy deplores these defacements, but proper restorations cannot be made every day, and Siena has good reason for bewailing several "restorations" that have been made.

From Tuscany passing into Æmilia we find in our way Bologna and Piacenza. At Bologna is a remarkable Palazzo Comunale, which makes us remember that this city — the *alma mater studiorum*, somewhat like Oxford, in England, and Boston, in the United States —

during the first half of the fourteenth century gave birth to a dynasty of eminent architects, the Fioravanti, who practised architecture at home and abroad; and to Fioravante Fioravanti is due the honor of having prepared the designs for the Palazzo Comunale and the court, whose imposing tower exercises a certain influence on the imagination. Far more important in its entirety and its details is the Palazzo Comunale at Piacenza, one of the finest models of Gothic architecture in brick in Italy. To tell the truth, this building, called "Il Gotico di Piacenza," is of mixed material. Its most interesting parts, the windows, are of brick, and these are the parts which give character and importance to the edifice. These windows have all the richness possible to brickwork, and the building is of all the town-halls in Italy the most highly decorated. Begun in 1281, it had several architects — Pietro Burgeto, Pietro Cagnano, Gherardo Campanario and Negro dei Negri; interrupted during the overthrow of the communal liberties, the façade which faces the grand piazza is only one of the four divisions of a building which was intended to enclose the courtyard, but of which nowadays we see only this part, although traces exist of the foundations.

"Il Gotico di Piacenza" below-stairs consists of an open vestibule on stone piers which leads to the courtyard, particularly important because of its details, and far from being equal on every side with the exterior. The palace has a façade, or a side, the left, where there is to be noticed a treatment of the windows surmounted by a rose window and a gable, with interlacing arches, constituting a perfectly harmonious treatment.

If I were to speak of communal palaces which were also fortresses, I should be apt to speak of the celebrated Castello dei Rocche at Finale in Æmilia amongst others, but they would form a subject which might better be treated elsewhere, as I should like to do.

Surely there exists nowhere in Italy a communal hall which can equal the glory of the Ducal Palace at Venice; the Palace of the Doges is the most beautiful of its kind in all Italy. Although the palace is very well known, my task is no less important, for the history of the Ducal Palace has almost always been based on imperfect data and on tradition rather than on serious documents.

The Ducal Palace at Venice, which rests against the right flank of the Golden Basilica, just as the Vatican rests against the right flank of the Basilica of St. Peter, has a very remote beginning. The first palace was erected in 814 by Agnello Partecipazio at a time when the ducal seat was transferred from Malamocco to Venice. A conflagration having reduced it to deplorable conditions in the time of the conspiracy against Candiano IV, the palace was restored by Pietro Orseolo in 976, then, ruined again by fire in 1105, it was rebuilt by the doge Ordelafo Faliero, and when the power was in the hands of Sebastiano Ziani it was enlarged, in 1173, and the works were carried on to 1340, when the rebuilding on the side of the Molo was begun, after designs, as obscure tradition has it, of Filippo Calendario; these works were carried on to 1355, resumed again in 1362, and finished in 1365. In the following century, or, to be more exact, in 1424, the façade upon the Piazzetta was begun, and finished in 1463 by such artists as Andrea da Milano, Giovanni and Bartolomeo Bon, the authors of the celebrated Porta della Carta, the Venetian master Pantaleone Bon and other sculptors and Tuscan ornamentists; then, in 1483, because of another fire, and later, in 1577, again because of a fire, the palace needed important repairs, which were carried out. All this shows that the Ducal Palace, far from being a Gothic construction of the Gothico-Oriental character common in Venice, is a mixture of styles, Gothic without, Renaissance within. So far as the details are concerned, there should be noticed the beauty of the capitals, carved by several artists, capitals of the porticos ornamented with leafage and figures which I myself have endeavored to study and explain in my "*Ornamenti dell' Architettura*," Vol. II, Page 85 and following, describing the capital of Justice, at the angle of the palace near the Porta della Carta, a *chef d'œuvre* of sculpture, the most beautiful capital that Italy can produce, signed by two Florentine artists. The chief artists who, at the time of the Renaissance, labored on the Ducal Palace were Antonio Rizzo, to whom we owe the celebrated Giants' Staircase, Pietro Lombardo, or Solari, and Antonio Abbondi, called "Il Scarpagnino." I need not speak of the romantic Bridge of Sighs which connects the Ducal Palace with the prisons, the work of Antonio Daponte (end of the sixteenth or beginning of the seventeenth century), nor of the façade on the Court of the Orologio, erected after the design of Bartolomeo Monopola, for the sake of enlarging the field of my present researches. Rather, I will point out the great beauty of the halls. Tiziano, Tintoretto, Paolo Veronese, Palma il Giovane are the painters of our palace, and their paintings and frescos are interwoven with carved marble doorways and chimneypieces, with bronzes and hangings, especially in that famous hall called the Sala del Maggior Consiglio, the most imposing room in the Ducal Palace, with Tintoretto's "Paradiso" and the "Glory of Venice" by Veronese, which taken together form an architectural and ornamental whole which produces a powerful impression.

Let us hope that the fear aroused in 1898 over the compromised stability of the Ducal Palace may be forever removed, as just now it seems as if it might be, and let us hope that the recent disaster to the Campanile of St. Mark may not have a sequence in the palace, which for several years back has been undergoing reinforcements and the lightening of the loads imposed on its foundations.

The Ducal Palace has been the object of recent restorations, the most memorable being the ones carried on with regularity from 1876 to 1889. There was at that time a kind of general reorganization, the decorative side concerning itself particularly with the exterior capitals, several of which were cut over amidst much opposition, particularly from Ruskin, who demanded that the old capitals should be replaced with plain uncarved blocks of marble. The restoration of 1873–89 is also memorable because of an ingenious wooden scaffolding invented by the architect Forcellini and used in the restorations.

Following now along the northern road while moving away from the Adriatic, I shall not halt at the ancient Broletto, or Arengario, at Monza (twelfth century), or at that of Brescia (begun in 1187), the one at Milan (thirteenth century) or that at Como (twelfth century), it being more agreeable to halt at Cremona, whose Communal Palace is a very imposing bit of brick architecture. Its origin is unknown, but it is certain that in the first years of the eleventh century a communal palace existed at Cremona, but the documents which relate to it do not necessarily refer to the present building, which does not date earlier than 1200; in fact, the front portion, on the piazza, was erected in 1206, and the façade of the court in 1245. Restorations have modified and disfigured it, and yet its Gothic character is very marked.

Cremona possesses another very remarkable Gothic building, the Palazzo di Gonfalonieri, which reminds one of "Il Gotico di Piacenza." This building was erected in 1292 by the captains of the army of citizens, and later was the seat of the jurisconsults, or advocates, from whence is derived the modern name of "wolf's staircase."

A Gothic palace which should not here be overlooked is the one which in the first years of the fourteenth century Guido Buonacolsi built at Mantua, carried on later from 1328 by the Gonzagas. Exteriorly, it preserves fairly enough its ancient lines, but within it has been wholly modified during the time of the Renaissance. The palace that I speak of is the celebrated Ducal Palace of Mantua, which recalls to us an heroic page in the history of our national painting, for it was here that the best artists of the fifteenth and sixteenth centuries executed their never-to-be-forgotten frescos and paintings from the time of Mantegna to Giulio Romano, and other exquisite performers in stucco decoration, marble and ebony-work here carried out work which even to-day excites admiration.

The interior of the Ducal Palace is, however, in great part in a most deplorable condition, but amateurs still find here reason enough for leaving the spot with their minds filled with sweet memories.

The North still calls us on to Genoa, where the Palazzo de S. Giorgio is one of the most precious monuments of this grand maritime city. This palace, which was built quite near the harbor on the *quai* bordering the sea, where the movement is intense, agitating, is always provoking long and interminable discussions on the necessity of surrendering a portion of itself to the demands of the merchants; but it has been resolved, in opposition to the demands of these gentlemen, that the Palazzo di S. Giorgio should remain as it was built by the Genoese powers of the thirteenth century, in the time of Guglielmo Boccanegra, by one of the most estimable men of his epoch, Father Oliviero dei Cistercensi (of the Carthusian brotherhood).

I have not yet spoken (now I am proceeding downward to the centre of the peninsula) of the Communal Palace of Perugia and the Palace of the Popes, or Soliano, at Orvieto, an elegant work due to the initiative of Pope Boniface VIII (1294–1302); nevertheless, properly speaking, the Gothic palace at Orvieto, while having all the air of a communal palace, does not come within the purview of my researches. So, limiting myself to the palace at Perugia, I will only mention its solemn air. Uncertainty veils its origin: it appears likely that its first architect was Father Benvignate da Perugia, (died 1310), who must have begun it in 1281; and this same palace has been the subject of a lively discussion because of a semicircular staircase which they wanted to plant against its façade. But my readers will be less interested with this discussion than with knowing that in the interior of the palace there exists a large hall, very richly decorated with frescos, an ornamentation which, unfortunately, has been over-restored in our days. Yet, this decoration is of a remarkable type for a hall of the Middle Ages. Without going far from Perugia, I will mention the Communal Palaces at Todi and Gubbio, sufficiently well known in Italy, particularly the latter. The palace at Gubbio, called "Dei Consoli," is generally attributed to Giovannello, surnamed "Il Gattapone," but this is a mistake, for the palace was built by Angelo d' Orvieto, who lived in the first half of the fourteenth century: the name of Gattapone has been brought forward without rhyme or reason, while the name of Angelo d' Orvieto is actually found engraved over the entrance to the palace.

If, leaving the communal palaces, I might enter on a consideration of the profane buildings of the Middle Ages, I should speak of Apulia. Abruzzi and Sicily, and I might mention the castle of Ortona de Marsi, the Castel del Monte, the Palazzo Tabassi at Sulmona, the elegant appearance of the Badia Vecchia at Taormina, a Gothic structure of the finest; and the Osterio, grand and small, at Cefalù, falsely attributed to the times of Roger II; but, since I must hold to my subject, I must bid farewell to my reader, content if my notes have interested him.

ALFREDO MELANI.

PARIS ARTS AND CRAFTS SCHOOL. — The erection of a school of arts and crafts has been decided upon by the Paris municipality, says the London *Times's* correspondent in the French capital. A spacious site has been chosen on the Boulevard de l'Hôpital. The school will cost 5,000,000f., the State contributing one-fourth of this amount.

SOUND-PROOF PARTITIONS.

THE subject of "fire-resistant partitions" and of "heat-resistant coverings for wooden surfaces" has long since been investigated on behalf of the Factory Mutual Fire Insurance Companies. There are many places in factories where it is desirable to put up partitions sufficiently light to be supported on the timbers without the necessity of building from the foundation. There are also many stairways, elevator-wells and belt-chambers in mills, where it is desirable to put up a fire-resistant partition without going to the heavy expense of encasing them in brick.

The materials and method of constructing such partitions vary with the conditions in each case. Thin metal, plastering on wire laths, expanded metal and other methods have been applied in different cases.

Among the heat-resistants, the Sackett's Plaster Board proved to be one of the most effective for covering wooden surfaces or partitions made of plank. This material is made ¾ inch in thickness and may be made thicker. It consists of four layers of felt and three layers of magnesium plaster. It is made in large sheets and may be fastened up in various ways at a moderate cost. It is then covered with "brown plastering" so-called, and finished with a skim coat of hard plaster. The partition occupies very small space; some which were put up in the office occupied by the undersigned, about two years since, without interfering with the daily work in any considerable measure, have proved to be free of cracks or any discoloration, taking up very little space. In this instance, the plaster board was nailed to seasoned wood-studding.

So far as we could judge, this material also retarded the passage of sound.

When the subject was submitted to Professor Norton by the architect in charge of the construction of a dormitory or dwelling-place for students in the New England Conservatory of Music, arrangements were made for including this material with others. The report of Professor Norton is herewith submitted.

Cabot's Quilt, recommended in connection with this material, is made of dry seaweed, padded between two thicknesses of paper, which, in buildings of fireproof construction, should be asbestos paper.

The architect in charge of the construction of the building of the New England Conservatory of Music, in which instruction is to be given, has adopted a partition of the Keystone Fireproofing Co.'s blocks with the Cabot's Quilt between the two sections.

These buildings are both approaching completion, so that ere long a practical test will be possible by which the relative sound-proof quality of each partition may be determined.

Respectfully submitted, EDWARD ATKINSON, *Director.*

BOSTON, MASS., August 8, 1902.

REPORT OF CHARLES L. NORTON: SOUND-PROOF PARTITIONS.

The subject of partitions for fireproof buildings is one which has led to much investigation, especially by the New York City Building Department.

When it is desired to make a partition which shall be reasonably sound-proof, it is apparently necessary to diminish somewhat the absolute incombustibility of the partition, though to a less extent than was supposed.

The following account of tests made for Mr. Edward T. Barker, architect of the dormitories of the New England Conservatory of Music, will show the relative values of some of the typical partitions of sound-proof separations between rooms: —

There were built upon the concrete floor of the B. & A. warehouse, East Boston, five rooms, 7 feet square, whose side walls were made of the several partitions. The rooms were built upon a floor of the same kind as that which is to be used in the buildings for the students of the Conservatory, for which the results of these tests were especially desired.

The rooms were built near one another on the fifth floor of the warehouse in a large loft or room about 50′ x 70′ long and 9 feet high. The ceiling of each room was the under surface of the concrete ceiling of the large room. Each room had a floor of two thicknesses of ⅞-inch floor-boards with *two* thicknesses of Cabot's Sheathing Quilt between the floor-boards and the concrete slab of the main floor. On one side of each room was a door with a glass panel, the door-jambs being faced with soft felt, and the bottom of the door was fitted with a stop, or "weather-strip," operated when the door closed, making a tight joint at the bottom.

The side with the door will be referred to as the front in the following description: —

Room A: This room was submitted by the National Fireproofing Co., and its four sides were made of terra-cotta blocks. The front and back walls were made of blocks 4 inches thick; the sides of 2-inch and 3-inch blocks. After the blocks were in position the room was given two coats of plaster inside and out.

Room B was submitted by the Keystone Block Co., and its four walls were made of the blocks of the Keystone material of the nature of plaster-of-Paris with a fibrous bond. The front wall was of blocks 4 inches thick, and the left side was of blocks 2 inches thick, the back of blocks 3 inches thick, and the right side of two 2-inch blocks with a 2-inch air-space between them. The entire room was given two coats of plaster inside and out, except the front, which had no plaster on the outside of the blocks.

Room C was submitted by the Sackett Wall Board Co. and was built of Sackett Plaster Board ¼ inch thick, wired upon both sides of 3-inch steel channels. The channel truss or studs of the back and right side were wrapped with felt about ⅛-inch in thickness before applying the plaster-board. The Sackett Plaster Board is a composite board of alternate layers of paper and plaster, the whole being about ¼ inch thick. This room, like the other, was plastered inside and out, but to a slightly less thickness.

Room D was submitted by J. Russell & Co. and was of a more complex construction. The left side was a solid partition of metallic lath and plaster. The ⅞-inch steel ties were spaced 16 inches on centres, metal lath was applied to one side only of the ties, and then plastered to a thickness of 2 inches. The rear wall was built upon two rows of ⅞-inch studs staggered. Between them were placed one thickness of waterproof paper about $\frac{1}{32}$ inch thick and metal lath was wired to both sides of the row of studs and given two coats of plaster. The right side was of the same construction with a layer of ⅛-inch felt between the two thicknesses of waterproof paper. The front wall was of metal lath on two rows of staggered studs, with Cabot's Seaweed Quilt between the rows of studs.

Room E was submitted by Mr. Samuel Cabot, and was wholly of metal lath and plaster double partitions, with the space between the lath filled with Cabot's Sheathing Quilt. The front and left sides contained three thicknesses of quilt, and the right side and rear two thicknesses. The quilt was placed between the studs and the metal lath, and where three thicknesses were used, one was between the row of studs as well.

The rooms had been vigorously dried for several days, none longer than a week, but the whole building was so damp and the time so short that no considerable part of the plaster and none of the interior portions of the partition were dry. The Sackett Board room was the driest and Cabot's was the least dry.

The preliminary trials showed so great a range of efficiency of the several constructions that the microphonic apparatus, which was designed to make rapid comparisons of sound intensity possible, could not be used. Reliance had to be placed wholly on listening with and without a felt-mouthed stethescope at the outside of the partition to sounds of various quality and intensity from within. The notes of the piano, violin, cornet and the human voice were carefully tried throughout wide ranges of pitch and intensity. The performers and the instruments were interchanged, every possible chance of unfairness, due to the variations of intensity in the sounds used, was eliminated. Of course, no interchange of the positions of the room was possible. No electrically-driven tuning-fork could be used for producing sounds of constant loudness. The insulating property of some of the partitions was so good that even the blare of a cornet or the overpowering tones of an Italian tenor, drawn from the ranks of the laborers on the building, could be heard through the partition, except by careful listening within a few inches of the wall.

After much consideration, the writer has given the following ratings to the different partitions. The order of their standing upon the list indicates their efficiency as compared with those above and below them.

No.	Room.	Side.	Scale.	Composition.
1	E	Left	100	Cabot's Quilt, 3 thick + metal lath.
2	E	Right	95	Cabot's Quilt, 2 thick + metal lath.
3	E	Rear	95	Cabot's Quilt, 2 thick + metal lath.
4	C	Rear	85	Sackett Board, 2 felt on ⊏ s.
5	C	Left	85	Sackett Board, 2 felt on ⊏.
6	C	Right	80	Sackett Board, 2 felt.
7	D	Rear	75	Metal lath + paper.
8	D	Right	75	Metal lath + paper + felt.
9	B	Right	60	Two 2″ Keystone Block with 2″ air-space.
10	A	Rear	50	4″ National Terra-cotta Blocks.
11	B	Rear	50	3″ Keystone Blocks.
12	A	Right	45	3″ National Terra-cotta Blocks.
13	B	Left	40	2″ Keystone Blocks.
14	A	Left	40	2″ National Terra-cotta Blocks.
15	D	Left	30	2″ Metal lath, solid plaster.

Nothing more is to be inferred from the numerical efficiencies than that the first partition is about three times as good as the last, and that the numerical interval between any two partitions on the list merely indicates the order of magnitude of the difference between the partitions.

The partitions making up the rooms submitted by Samuel Cabot and the Sackett Wall Board Company were the most efficient; but it is distinctly to be borne in mind that no other room had so easy a test as did these, in that each of the others had one thin and ineffective side which transmitted sound to the sides adjacent to it. The thin side of the Keystone room was noticeably resonant and plainly rendered it impossible to make a fully satisfactory test of the air-space partition. The solid metal-lath plaster partition of the room submitted by J. Russell & Co. acted in the same way in that room.

I do not believe, however, that this defect in the structures has caused any changes in the position on the efficiency list of the Cabot and Sackett rooms.

The efficiency of the Cabot Quilt as a material for rendering the partition "sound-proof" is so clearly demonstrated in these tests that I recommend it for use in the partitions for which these tests were made. The nature of the material in which the Quilt is encased should be carefully considered. I do not think it within the province

of this report to discuss the partition from other than acoustic considerations, and as an encasing medium the most effective material is Sackett Board and Adamant Plaster.

I would, therefore, give as my opinion that the best acoustic results would be attained by using a partition of Sackett Board and plaster with two thicknesses of Cabot's Quilt between the plaster-board.

I should recommend a wooden stud rather than steel channels, if the fire-risk is not materially increased thereby.

As later tests showed, some sort of a suspended ceiling will be needed, as the concrete slab transmits the sound across the top of the partition readily. No trouble will be given by the sound passing through the concrete to the rooms above or below; but, unless a layer of Cabot's Quilt, with under-lath and plaster, or of Sackett Board and plaster be put on the under side of the concrete ceiling, the efficiency of the partitions will be diminished somewhat.

The front walls could not be tested because of the leaks around the door and through the door-frames, even where covered with a large shutter padded with Cabot's Quilt. It is evident that a double glass door will be needed. The floor construction is acoustically good. Respectfully submitted, C. L. NORTON.

IS THE ARCHITECT A BLACKMAILER?

THE following remarks, published in last week's issue of the *Record and Guide*, so entirely coincide with opinions which we have more than once expressed on the subject of exhibition catalogues, that we gladly take the opportunity to reprint them with permission, for the sake of showing that we are not singular in entertaining them: —

It has long been recognized that one of the greatest obstacles to reform is the timidity of the suffering and the virtuous. Those people who suffer most from an abuse, as well as those who are most familiar with its operation, refuse to lift up their voices in public either for the benefit of themselves or their fellows. They vociferate secretly and denounce privately, but when called upon to give effective testimony, in order to secure the punishment of rascality, or the correction of an evil, they shirk the ordeal with a cowardice that makes the spectator respect even the crime or the oppression of which the victims themselves complain.

Every newspaper-office is thoroughly familiar with this reformer "without a name" — this man who, in regard to public abuses, would write letters, which he will not sign, this civic weakling, willing to give important evidence only on condition that his incognito is sacredly preserved.

For some years past the *Record and Guide* has been hotly importuned by a number of building-material firms and others in this city in regard to what they are pleased to call the "blackmail" practised by the architectural profession in general. This "blackmail," it is alleged, is exerted in many ways, through the medium of exhibitions, catalogues, commissions, but depends, in all cases, essentially upon the fact that the architect, as purchasing-agent for his client, considers himself entitled to "propitiation" from the building-material houses with which he deals, thus making it at least dangerous to refuse tribute to the enterprises, schemes or interests which receive his endorsement, or with which he happens to be connected.

A building, let us say, is erected. As soon as it is finished a prospectus or catalogue is produced, describing the building, illustrating the street-front and giving floor-plans. The architect supplies the drawings. His name figures prominently in the pages. Every contractor or building-material firm who has done a dollar's worth of work or supplied a dollar's worth of material is solicited for a contribution under the guise of "advertising." Some firms contribute perhaps $50 or $100. The outlay stands on the books of the building-material firm as an expenditure for advertising, but it is regarded by the house strictly as "backsheesh."

"Scarcely a day goes by now," complains the manager of a large concern, "without our being called upon to 'stand and deliver,' in the name of some architectural exhibition, some annual catalogue, some club or society publication or architects' pamphlet. In many cases we are given plainly enough to understand what is expected of us. In other cases, the 'blackmailed' hand is gloved, and all we see is the names of a number of leading architects placed on a letter-head, soliciting, mark you, soliciting our advertisement! I have one such letter now before me.

"Sometimes these schemes are boldly entrusted to advertising-agencies. Frequently, indeed, they are actually farmed out to these people. I could tell you, and so could others tell you, of how the names of apparently honorable men in the profession have been used by these agencies in a way that would make the owners blush for shame."

Another firm whose book-keeping methods possess the virtue of candor have actually opened an account headed "Blackmail." We had the privilege of looking at it recently and found among the items the names of several highly respected architectural and building organizations in different parts of this country where the firm had a considerable market. In speaking to one of the officers of the company, we were told: "We are merely waiting until the evil reaches the breaking point. It is fast getting there. It is something like the Tammany police system; it doesn't pay any one individual to fight it alone. It is cheaper to grin and sign a check for the petty larceny. Last year we were called upon to pay out something like $2,000 for 'exhibitions,' professional catalogues, organization publications, and the like.

"I cannot believe that the honorable members of the architectural profession and the building-trades realize what is being done with their apparent sanction. It is time they did. If, in the judgment of these people, it is desirable to hold annual exhibitions, issue club publications and print catalogues, should it not be done at the cost of the beneficiaries? Take for instance, these architectural exhibitions that are held in the chief cities of the country. Is not every one of them carried on mainly at the expense of building-material firms? The architect will tell you he doesn't advertise. Oh, no! Such a commercial method of seeking fame is unprofessional! Nevertheless, he permits his agents to approach building-material firms in his name, extract money from them, and then, with that extorted cash, he exhibits his own drawings to an admiring public, thus obtaining in an indirect way and at the expense of others, the publicity which he is not candid enough to say he appreciates, or independent enough to pay for from his own purse."

These are serious indictments. We believe that no one will more quickly or more honestly repudiate them than our architects and builders themselves. But that is only the personal side of the matter. The fact is, the evils complained of have developed through a certain moral carelessness or a certain financial optimism, which makes people when associated for a common purpose other than a directly pecuniary one somewhat incurious as to the exact source of the dollars that come to them. Moreover, there is a certain specious side to the situation that may well blind an insensitive person. No one, it may be said, is bound to advertise in these catalogues or contribute to these exhibitions. There is no compulsion. If firms sign a contract for advertising-space, presumably it is because they deem the publicity they get of a value equivalent to their cash. This argument is fallacious. It doesn't touch the realities of the case. Similar statements might be made regarding the tyranny of the tipping-system and of all other forms of general blackmail. In all these extortions people "put up" as though their payments were really voluntary, but essentially, there is coercion, and every man feels it. The men who canvass for these schemes might indeed repudiate the word "blackmail," yet they all know very well how much power there is in "suggestion," and do not delude themselves for a moment that they are engaged in presenting a thoroughly business proposition to those who give them an audience. They know there is an uncommercial element in the proposition, and they know that it is just that very uncommercial element that is most potent in obtaining the signatures to the contracts from which these architectural, building and other societies derive the benefit.

The truth of the situation could very easily be discovered by a small committee, intent upon getting the truth, were they to visit fifty of the chief victims in this city alone, and have with them a private, candid and quite unperfunctory conversation. They would learn enough to enable them to make a report that would cause every honorable man to withdraw his name from these exhibitions, publications and catalogues, in which the real beneficiaries are not the persons who pay the bills.

The architect is prone to talk much of his professionality. The most professional step that is open to the architect of this country today is to rigorously pay his own bills for the exhibition of his own drawings and to cease farming out his professional dignity and his professional name for a price. This is about equally true of builders throughout this country, though, of course, for reasons not concerned with professional ethics. It is also true of labor organizations. They are all offenders. Yet the offense from every point-of-view is a mistake. No good cause is really served by contributory petty enterprises based on extortion. It is time a stop were put to the evil. It has attained great proportions. It is much talked of and inwardly opposed. But "publication" is another matter, and complaints and appeals are forwarded to the *Record and Guide* only on condition of secrecy. We hope yet to remove that, or, rather, conditions are now so near to the point of intoleration that it will be cheaper to speak out than to pay up.

BOOKS AND PAPERS

IT it not easy to write anything very original upon the subject of steam-heating and ventilation, for while it is quite possible that such writers as Baldwin, Mills and Carpenter have not uttered the last word upon such subjects, it is nevertheless almost inevitable that any new work should follow the same lines that these authors have beaten out so well and should of necessity constantly refer to them as standard authorities. This recent addition to the technical library on the subject [1] was originally written as a series of articles for the *Engineering Record* and has been somewhat revised for its present form. The subject-matter is treated simply and in a perfectly comprehensible manner and the principles of the science and application thereof are set forth in such a manner as to be readily available, and while in no sense exhaustive or strikingly original, it is a trustworthy guide to the practice of those who have this sort of work to do. Heating and ventilation is essentially a practical science in which it is safe to say that more depends upon knowledge of good practice

[1] "*Steam Heating and Ventilation.*" By William S. Monroe, M. E. Price $2.00. New York; *The Engineering Record*, 1902.

than of the theory, especially as all the theories relating to the proportioning of heating-surfaces are almost purely empirical. The author admits the lack of usual information in regard to this branch of the subject, but it is to be regretted that he could not have managed to collect in available form some of the experience which has certainly proved satisfactory in the past. In the earlier days of steam-heating radiating-surfaces were generally figured by rule-of-thumb methods based upon the cubic contents of the space to be heated. The writer gives considerable study to the endeavors to devise a more scientific method of analysis which would take account of the loss of heat through different mediums and through different kinds of construction, but at the best such methods of analysis have little tangible value unless they can be substantiated by actual observation, and in ordinary practice it is found on the whole quite as safe, and far easier, to lay out the radiating-surfaces in proportion to the cubic contents of a room, varying the proportion to meet the varying requirements. It is safe to say that no one, however well posted theoretically, could be trusted to design the heating-apparatus for a large building unless he has had practical experience.

It is to be regretted that the writer seems to advise the concealment of risers in fireproof buildings. This is a thoroughly bad practice and is not to be defended even upon the score of looks, while from every practical standpoint the risers should never be concealed except in vertical ducts which are readily accessible.

On the whole, the work is a concise, practical manual embodying and illustrating the best of the common practice.

Mr. Cain's work on the Theory of Steel-Concrete Arches [1] is the best and most available treatise upon the subject which has come under our notice. The analyses of the strains in an arch are necessarily worked out in a more or less empirical manner and assumptions have to be made as to lines of action of forces which are doubtless not in exact accordance with the real conditions, so that the solution of the strains in an arch is indeterminate, but the reasoning is very logical and gives results which are trustworthy, while the methods are, on the whole, the best which we have seen presented. The book is to be commended to all who are interested in this kind of work.

ILLUSTRATIONS

[*Contributors of drawings are requested to send also plans and a full and adequate description of the buildings, including a statement of cost.*]

THE DUCAL PALACE, VENICE, ITALY; — PALAZZO PUBBLICO, PERUGIA, ITALY.

THE LOUISIANA PURCHASE EXPOSITION, ST. LOUIS, MO.: A CORNER OF THE TEXTILES BUILDING. MESSRS. EAMES & YOUNG, ARCHITECTS, ST. LOUIS, MO.; — THE FINE-ARTS BUILDING. MR. CASS GILBERT, ARCHITECT, NEW YORK, N. Y.

The Textiles Building is situated to the left of the main lagoon, and this and the Electricity and Machinery Building are the only two buildings facing the Grand Basins with the cascades and approaches to the terrace crowning the hill on which the Art Building stands. While not the largest in area, the building fronts 525 feet on the main thoroughfare of the Exposition. Its position makes it one of the most conspicuous buildings, in what has been called the "Main Picture" of the Exposition. The four elevations are similar in character, varying only as required by the irregular shape of the ground plan. The interior court will follow the general outline of the buildings in form and style, and will be laid out in the form of a plaisance or garden of a formal type. It is estimated that the cost of this building will be about $600,000. It will be wholly temporary in character, and will be constructed of staff, or other similar material.

The Art Palaces consist of a group of three buildings, having a total frontage in the northwest façade of 836 feet. The middle building is 166′ x 348′ and is of the most substantial and enduring fireproof construction. This building will contain a hall for statuary 94′ x 157′, with an arched ceiling 51 feet high. Picture-galleries will have places on either side of the sculpture-hall. The two pavilions at either side are of temporary construction, each being 200′ x 422′ in size. Each will stand 44 feet from the central building. A court 262′ x 530′ south of the central building, enclosed on three sides, will receive a rich decoration in landscape effect and will be one of the many delightful resting-places to be found in the Exposition. The lighting of the buildings will be principally from clerestory windows, so that the entire interior side-wall space may be available for pictures.

COMMUNICATIONS

[*The editors cannot pay attention to demands of correspondents who forget to give their names and addresses as guaranty of good faith; nor do they hold themselves responsible for opinions expressed by their correspondents.*]

A VOICE FROM THE COAL REGION.

Wilkesbarre, Pa., September 30, 1902.

To the Editors of the American Architect: —

Dear Sirs, — I wish to thank you for the sane articles on the strike question which are in the September 27th number of the *Architect*. If the newspapers in general and the parsons and philanthropists so-called could profit by them it would be a blessing indeed. So few people outside the coal region understand the fight for American liberty which the operators are maintaining, or have any sympathy with the men who want to work and are not allowed to do so, that it is refreshing to find some one who understands the whole situation.

Gratefully yours, An American Woman.

NOTES AND CLIPPINGS

Light and Air in Cities. — In New York the importance of the light-and-air question is now pretty well understood, though it has been egregiously overlooked in several instances; and the result is that large office-buildings are attempted only on especially favorable sites, the majority of which have already been preëmpted. The influence of the Trinity churchyard, in affecting realty valuations, is an interesting case in point. Here is an open green square in the heart of the financial centre, which sentiment and tradition have made consecrated ground; which the wealthy proprietary corporation refuses to sell at any price; and which, as far as can now be seen, will always remain in its present state. Consequently, the office-buildings erected on abutting property are assured of a splendid supply of light and air for an indefinite period. It is for this reason that the Empire Building, on the south side of Rector Street, is one of the most successful enterprises in the Metropolis; and it is for this reason that the old Trinity Building, at 111 Broadway, is regarded as probably the most available building site in the lower business district. — *B. J. Hendrick in the October Atlantic.*

Difficult Engineering in the New York Subway. — Mr. Frank W. Skinner of the *Engineering Record* has a paper in the October *Century* on the above topic, in which he describes the running of the subway under the Columbus Monument, and the moving of a tunnel. He also gives this account of the relocating of a long, thin, high wall: "An ordinary derrick will handle compact loads of 3, 5, or even 10 tons; a 100-ton load is about the limit of the capacity of the heaviest steel ordnance cars drawn by powerful locomotives, or of the largest hydraulic jacks, which will lift it a few inches so slowly that the motion is scarcely perceptible. A building weighing 500 tons may be carefully braced and lifted up or moved laterally with rollers on smooth level

---

[1] "*Theory of Steel-Concrete Arches, and of Vaulted Structures.*" By William Cain, Member Am. Soc. C. E., Professor of Mathematics, University of North Carolina. Second edition, thoroughly revised. Price 50 cents. New York: D. Van Nostrand Company, Nos. 23 Murray and 27 Warren Sts. 1902.

tracks by the help of scores of powerful jacks. It would require immense power to push along even a 50-ton boulder resting on the ground, and be yet more difficult to move a long, thin, high wall several feet transversely without cracking, tipping or twisting it. Generally, when such a wall is to be relocated, it is taken down and rebuilt; but such was not the case on the subway above 135th Street, where, at the entrance to a tunnel-section, walls nearly 200 feet long retain the bank on each side of the cut. After the structure was completed it was decided to widen it 11 feet to receive a third track, and although it was at first intended to tear down the masonry and build new, it was finally decided to move it bodily, and this was successfully accomplished at a saving of several thousand dollars. The walls are of concrete and brick, 13 feet high at one end, 3 feet thick on top, and weigh about 400,000 pounds each. The earth was dug away behind them for a width of 6 feet, and to a depth a little below their foundations. In the bottom of each trench a concrete floor was laid just below the level of the foot of the wall. Small holes were tunnelled under the wall a few feet apart, and in them were laid transverse timbers reaching to the floor of the trench and having both ends supported on cross-sills. Narrow, thin, greased steel track-plates were inserted under the walls, on top of the timbers, and extended across the trench floors. Small steel bearing-plates were set on the track-plates under the front and rear edges of the walls, and pairs of oak wedges, driven between the cross-timbers and their sills, lifted the whole wall on the steel-plates. Horizontal 5-ton jack-screws were set close together against the face of the wall at the base for its whole length, and being simultaneously operated, the wall in a few hours was moved back 5½ feet on the floor in the trench. The projecting ends of the track-plates were cut off, and the spaces between the plates under the wall were filled with liquid cement. The work on each wall was done by twenty men in ten days, and the walls were not distorted the sixteenth of an inch."

Statues of Bruand and Hardouin-Mansart. — Among the projects under the consideration of the Paris Municipal Council is one for the erection of two statues in the Square de Breteuil, the subjects being Liberal Bruand and Jules Hardouin-Mansart. Bruand's name is seldom mentioned, although he prepared the original design for the Invalides. Mansart's name is, on the contrary, familiar to Frenchmen, and it is surprising that an artist who is so identified with the national architecture should still be without a statue in Paris. One reason may arise from the difficulty of distinguishing between the various members of the family. Nicholas from an early age was entrusted with great buildings in Paris. One of them was the mansion now used for the Bank of France. He began the great church of Val de Grâce, but the upper part, including the dome, is the work of Le Mercier. Hardouin-Mansart, who was the pupil of Bruand, was for about thirty years engaged on the works at Versailles. He completed the Invalides with the exception of the dome, which he designed and partly carried out. There was another member of the family, who was engaged on the church of St. Eustache. We presume there can be no objection to statues of the two artists. It is true they were both Royalists, but it would be unfair to make them responsible for the shortcomings of the age in which they lived. — *The Architect.*

Gift to the Irish National Gallery. — The Countess of Milltown has made a most generous gift to the nation, which will be highly appreciated by the Irish people among whom she has lived so long. She has made over by deed to the National Gallery in Dublin all the splendid pictures, plate, furniture, and other objects of value in her residence, Russborough, Blessington (County Wicklow), and directs them to be kept in separate rooms, and marked as the Milltown Museum. Thus, the Irish National Gallery will have the unique advantage of showing the whole furniture of a stately country house, built and adorned in the best period — towards the end of the eighteenth century. The donor of this interesting and remarkable gift is a daughter of the fifth Earl of Harrington, and married in 1871 the sixth Earl of Milltown, who died in 1890. He left no children, and the peerage went to his brother, who only held it for a year, when he also expired without heirs, and the title became extinct. There are, however, two claimants to it, descendants of sons of the third Earl, but neither of them has, as yet, established his right, and the title no longer appears on the Ulster roll. — *London Telegraph.*

Acoustic Changes at the Prince Regent's Theatre, Munich. — Few opera-houses in any country are acoustically satisfactory. In the past there was a belief that it was all a matter of luck, and that, if the architect did not accidentally stumble onto the right thing, the public would have to submit to its fate, with Oriental resignation. We know better now. The changes made in the new Prince Regent's Theatre in Munich last year show how much can be done to mend matters. Otto Lessmann describes these changes in the *Allgemeine Musik Zeitung* for August 29, and attests that "the orchestral sound has gained much in softness and refinement, without any loss of brilliancy. The individual parts of the body instrumental can now be distinguished, even in the most complex polyphony, with surprising clearness. The brasses, which last year were hard and blaring, now have a soft metallic clang, while the mighty body of strings gives forth sounds which are ideally beautiful in *forte* as well as in *piano*. In a word, the improvement of the acoustics is astounding, and I believe that from the tonal point-of-view the Munich festival theatre now equals that of Bayreuth." — *N. Y. Evening Post.*

An Exhibition of Paris Shop-signs. — For some months past the idea of an exhibition of shop-signs has been fructifying in the mind of M. Detaille, the well-known painter of battle-scenes. Now the project has taken definite shape, and has for godfather the Prefect of the Seine, M. Selves. Notices have been issued giving particulars of the exhibition, which is to take place in October next. The wish of M. Detaille and his brother-artists associated with him on the committee is to revive the old signs that were such a picturesque feature of Paris of fifty years ago. Here and there one meets portions of the old streets incorporated in the new boulevards, quaint old houses with their old signs still attaching to the little narrow shop-fronts. There are, indeed, some interesting trade-symbols in various parts of the city, some but newly installed. In the Rue Bonaparte, for instance, a tradesman has recently raised a sign above his premises, which bears the figure of Napoleon mounted upon his white horse. Oddly enough, the name of the tradesman is Lempereur. The sweep and the barber have very largely conserved their ancient distinctions, and, indeed, there is a very common tendency in the ornamentation of the building to call attention to the wares of the tenant. The florists, however, who show such exquisite taste in the arrangement of their windows, have, as a trade, adopted a sign which is as lugubrious and unpleasant as can well be imagined — a composition funeral wreath. It is needless to say that the committee will not encourage designs of that sort; rather we may expect to see a revival of the arts of the cunning smith who with his own strong hands forges a graceful bracket for a swinging board. It has been pointed out that the painted sign is a remnant of the age when the public as a mass, unable to read, possessed this sole means of identification of a particular establishment. In that sense, the sign has ceased to be necessary. Nevertheless, the artistic sign will add to the amenities of the pleasant streets of Paris, even if there is no direct furtherance of trade. — *Pall-Mall Gazette.*

Japanese Investigation of Buddhist Remains. — A remarkable illustration of Japanese enterprise and advancement is an archæological expedition which has just left for Central Asia under the management of Count Otani Kozui and M. Watanabe Tetsushin, both Members of the Japan Society. Count Otani is also a Member of the Royal Geographical Society of London. The purpose of the expedition is to search for the Buddhistic remains in Central Asia, India, and China, and to trace as far as is possible the course of Buddhism from its source northwards and eastwards to Japan. The members of the party, seven in number, are all Japanese. Count Otani's father, Otani Kozon, now living in Kioto, is Lord Abbott of Nishi Hon-gwan-ji, the monastery of the "Original Vow," and a direct descendant of Shinran, the richest founder of the Shin Shin sect, who lived in the eleventh century. Count Otani Kozui has been an extensive traveller, and was elected a Member of the Royal Geographical Society because of his explorations in China. His father sent him to Jerusalem to study Christianity and Mohammedanism, and on his own initiative he visited Iceland and spent the best part of a year in the Arctic Circle. He is an enthusiastic student of Sanskrit and ancient Chinese, and has done much original work in the Oriental room of the British Museum. All the members of the expedition have been preparing for this work for several years. M. Watanabe Tetsushin has been studying church history with a priest of the Church of England, and has paid particular attention to the Nestorians, who wandered from Constantinople off into Asia in the fifth century. He lived in St. Petersburg one year and speaks Russian fluently. M. Hori Masuo, who will look after the surveys and the map-making, has been studying topography in Oxford. M. Inongo Koen, a veteran of the Chino-Japanese war, will have charge of the transport; M. Fujii Sensho, Ph. D., is well versed in Chinese and Japanese Buddhistic literature. He has been studying Sanskrit in Berlin and Paris, and has already been several times in India. — *N. Y. Evening Post.*

Coal Briquettes in Germany. — The manufacture and use of briquettes in Germany, an article of fuel composed of brown coal, peat and the dust and waste from coal-mines, has developed to such important proportions in recent years as to attract wide attention, especially at this time. The following tabulated statement shows the amount and the prices for a period of eleven years: —

	Production (Tons).	Sales of Syndicate (Tons).	Price Per Ton.
1891	482,495	202,780	$3.02
1892	533,075	516,508	2.49
1893	694,025	645,144	2.16
1894	745,414	719,258	2.10
1895	796,363	780,185	2.16
1896	830,985	818,300	2.22
1897	943,732	934,221	2.38
1898	1,078,113	1,245,269	2.43
1899	1,530,816	1,485,130	2.34
1890	1,563,928	1,519,811	2.92
1901	1,566,385	1,560,230	3.17

This kind of briquette forms the principal domestic fuel in Berlin and other cities in Germany, and is used also in locomotives and manufacturing industries. It is clean and convenient to handle, lights quickly and burns with a clear, intense flame, and the combustion is practically smokeless. Hence, Berlin, though a busy manufacturing city, is one of the cleanest cities in Europe, so far as smoke is concerned. Like most other important German industries, this is controlled by a syndicate which includes thirty-one firms and companies, or more than nine-tenths of all the producers in the country, and which regulates the output and prices. Yet the prices remain comparatively low and are commensurate with the means of the poorer classes. Of the 1,566,385 tons sold by the syndicate last year, 749,208 tons were taken by the German railways, 124,380 tons were sold to retailers, 497,136 tons were sold to factories and works of various kinds, and 149,089 tons, or 9.8 per cent, were used by German merchant-steamers and the navy or exported to the German colonies or neighboring European countries. — *Boston Transcript.*

Shakespeare Statue at Elsinore. — A committee has been formed to erect a statue of William Shakespeare in the open space opposite the so-called "Hamlet Terrace" of Kronborg Castle, at Elsinore, Denmark. — *Exchange.*

NOTES AND CLIPPINGS. 16

IT must be confessed that the results of the interview between the President, Mr. Mitchell and the coal operators do not cast much credit upon the intelligence of the operators. It was presumed by the public, and, probably, by Mr. Roosevelt, that the operators, after hearing what Mr. Mitchell had to say, would present a reply to his proposals. Instead of this, there is, practically, no evidence that they even listened to what he said, much less gave it any rational consideration. If, instead of composing rambling denunciations of anarchy in general, and extolling their own virtue in standing up for the principle of freedom of labor, they had attended to Mr. Mitchell's words, they would have seen that he was making them and the country a straightforward and unequivocal offer of everything that they represent themselves as contending for, in his proposition to leave all the points at issue to the President, or to commissioners appointed by him, the award to be binding on all parties. The operators say that they are fighting for the right of non-union men to work in the mines without molestation. It is inconceivable that the President, or any commissioners appointed by him, would deny that right, so that an acceptance of Mr. Mitchell's offer would at once have accomplished the object for which, as the operators say, they are sacrificing themselves and other people. The only other points, apparently, which would come before the commissioners would be those relating to wages and "improved environment," and it is safe to say that neither President Roosevelt nor any commissioners of his choosing would be unreasonable in regard to them. The lying, in regard to these matters, is at present something frightful, the miners declaring that they are compelled to live in abject misery, on incomes of forty or fifty dollars a month, while the operators affirm that the average miner earns about three dollars and a half in five hours of every day, and invests his surplus income in real-estate and savings-bank deposits; but any commission with common-sense would soon ascertain the facts, and if it found that undeserved misery really existed, and could be cured by a reasonable increase of wages, the whole American people would approve an award providing for such increase.

THE trouble about coming to an agreement seems to have been that the operators present at the meeting were so blinded by their private prejudices that they could not even see their own interest, much less that of their men and the public. The idea of combining all the anthracite miners into one organization, which appears to the public quite as legitimate as a combination of the operators, seemed to work on their feelings as the shaking of a red rag does on those of a bull; while their grief and despair on account of the violent acts committed by the striking miners, which Mr. Mitchell probably deprecates as much as they do, prevented them, apparently, from listening to a proposition which would immediately put a stop to such violent acts, without endangering any of the objects which they profess to cherish. If we imagine Grant, at Appomattox, driving off the messengers who brought him Lee's flag of truce on the ground that his "principles" would not allow him to have anything to do with a representative of secession, or to enter into any negotiations so long as "violence" continued in the South; and that, rather than accept the sword of such an odious person, he would continue fighting until the last man on both sides had fallen, we shall have a good illustration of the attitude which the operators seem to have thought fit to assume before the President and the public. It is not difficult to imagine what military fate would await a general who carried on negotiations in this spirit; and it is possible that the stockholders of the coal roads, which are now not earning their operating expenses, may solve the great problem by putting in charge of their property men who can comprehend an opportunity when it is offered them.

IT is one of the weaknesses of trusts, a weakness which has already proved fatal to some, and is likely to bring about the ruin, or, at least, the dissolution, of many others, that they almost completely eliminate the personal initiative, and the quick decision in taking advantage of favorable circumstances, on which business success depends. A single operator, trained to foresee the consequences of every movement affecting his business, responsible only to himself, and enjoying full authority to decide all questions as he may see fit, without explaining his reasons to anybody, would, if of ordinary intelligence, have closed with Mr. Mitchell's proposition on the spot; but with a number of officials, of equal authority, and bound by agreement to act together, the sense of responsibility in each is so slight, and the difficulty of getting them all to comprehend any proposed action is so great, that anything like a rapid act of intelligence is not to be expected from them; and, unless they act simply as unquestioning instruments in the hand of some one person of preëminent ability, which very rarely happens, they soon fall into the habit of dull obstructiveness which is so marked a characteristic of trust administration, and which was so strikingly displayed at the Roosevelt interview. Ultimately, this sort of management generally comes to grief, in business matters, before the competition of individual alertness and decision; but neither the public nor the stockholders in the coal roads can wait until circumstances have taught their officials to reply to an advantageous business proposition by something else than discourses on their services in the Civil War, and the sooner the people who own the property which is being sacrificed take the control of it, the better it will be for everybody.

THE engineering world, which, in Germany, includes the architectural world, laments the death of James Hobrecht, one of the most famous of modern engineers, and the author of the Berlin sewerage system, in many respects the best ever devised for a great city. More than forty years ago, the municipal government of Berlin sent an engineer Commissioner to England and France, to study the most improved drainage systems of inland cities, with a view to their application to the needs of Berlin, and with this Commissioner was sent James Hobrecht, then a young architect, as assistant. Hobrecht was a skilful draughtsman, and his sketches served, after the return of the party, to illustrate the report of the Commissioner on the "Drainage of Berlin." The Commissioner, Wiebe, was, as a result of his investigations, charged with the preparation of a plan for the sewerage of the city; and, according to the practice then in vogue, he drew up a scheme by which the little river Spree was made to receive all the drainage of what, even then, was a city of five hundred and fifty thousand inhabitants. Hobrecht, more far-seeing, appreciated the difficulties which would result from loading a little fresh-water stream, far from the sea, with the sewage of a great and growing city, and made up his mind that the only successful method of disposal must be sought in some form of irrigation, for which the flat, sandy plain surrounding the city afforded certain advantages.

Entered at the Post-Office at Boston as second-class matter

Although Milan and Edinburgh had practised sewage irrigation on a small scale for some years, no great city had yet attempted it; and all Hobrecht's enthusiasm and force of character were required to persuade the Berlin authorities of its practicability. The plan of Wiebe, for pouring a flood of sewage into the Spree, was, however, set aside in the meanwhile, and it was finally decided to adopt, in general, the project that Hobrecht advocated. Fortunately, this project was a comprehensive one, and, although Berlin has now nearly two million inhabitants, and certain details of the system have been modified in extending it, the irrigation-fields still dispose of the drainage satisfactorily. At this time, when nearly every great city in Europe has adopted the irrigation system, it is hard to realize the difficulties under which the young German architect labored in bringing the municipal authorities, as well as the people of the city, to the comprehension and appreciation of his views. Fortunately, he was endowed by nature with great courage and perseverance, and he enjoyed, in addition, that confidence and support of his fellow engineers and architects which is so precious to the professional man, and which the German architects and engineers bestow upon each other so generously and intelligently. The architects, in particular, who always considered him as one of themselves, although his work was rather engineering than architectural, made him a Director of the Berlin Architectural Society, and, for many years, enjoyed his counsel and sympathy as much, no doubt, as he did theirs. After his great work at Berlin was complete, he was immediately called to carry out similar undertakings elsewhere, and Moscow, Tokio, Cairo and Alexandria, besides Stettin and Darmstadt, owe to him their drainage systems.

ARCHITECTS will be interested to learn the limit of size to which it is practicable to turn and polish granite columns in this country. In the new Episcopal Cathedral in New York, provision is made for eight columns, the shafts of which, of polished granite, are fifty-four feet long, and six feet in diameter. There seems to be no difficulty in getting these shafts as monoliths out of the quarry; but, in order to polish them, they must be put in a lathe, and, after several years' trial, the contractor, Mr. John Pierce, has come to the conclusion that it is impracticable, with any machinery now in use, to support the columns in such a way that they will not break, from their own weight, while being turned. The turning itself presents no great difficulty, as lathes capable of turning a cannon sixty feet long have been for many years in use; but a cannon needs little or no support in the middle while being turned, whereas a granite cylinder, nine diameters long, supported only at the ends, cannot be depended upon to sustain its own weight. If it were possible to rest the middle portion on a support of some kind, the strain would be greatly diminished, but, in the nature of things, it is impracticable to give a stone, which is comparatively rough when put into the lathe, a firm support of this sort. The Trustees of the Cathedral, on being informed of the circumstances, have authorized the making of these shafts in two pieces, one thirty-six feet long, and the other eighteen. Only three of the columns are as yet ordered, the intention being to erect them by subscription, as memorials of distinguished persons. They cost about sixteen thousand dollars each, so that they do not form a very expensive monument, and it would be difficult to devise a more effective one for the money.

THE National Arts Club, of New York, repeats its invitation to all persons interested to join in its contribution toward the rebuilding of the Venetian Campanile. About six hundred dollars was subscribed among members of the Club immediately after the catastrophe, and, as the Syndic of Venice, Count Grimani, has assured the Club that its contribution will be received with "the heartfelt thanks" of the city of Venice for its interest and sympathy, the Committee of the Club feels justified in again inviting all Americans who would like to be associated with the gift to send contributions, of any size, to its Treasurer, Mr. Spencer Trask, 27 Pine Street, New York.

THE timber lands of the Northwest, which, a few years ago, were supposed to be practically inexhaustible, have fallen mostly into the hands of syndicates of speculators, who, as they now control the supply of lumber, have raised prices very materially; and the people of the Pacific Coast will have to pay the advance. Undoubtedly, in California and Oregon, as in Minnesota, Iowa and other Western States, the result of the increase in prices will be to excite a popular demand for the repeal of the duties on lumber; but, even with Canadian lumber admitted free, the cost of timber building is likely to rise, with occasional fluctuations, until construction with more substantial materials becomes the rule here, even in country districts, as it is everywhere in Europe except in the forest districts. That the art of architecture will gain by the change there can hardly be any question. Our wooden houses are well planned, convenient, neat, and occasionally picturesque, but they rarely have anything of real fine-art about them, and age and decay, instead of making them more beautiful, as is often the case with stone buildings, and sometimes with those of brick and terra-cotta, give them a peculiarly repulsive meanness. It is curious that, with all our boasted science, our facilities for transportation, and our unrivalled cements, it seems to be impossible for us to approach the perfection of construction of, let us say, the fourteenth or fifteenth century. Most architects are familiar with the Hôtel Cluny, in Paris, whose perfection of material and workmanship, after exposure to the elements for four hundred years, puts to shame the cracked and dislocated masonry, the leaning and crooked walls, and the open joints, of almost all our most costly buildings. The experienced eye of the architect shows him, as he passes through our city streets, that very few of the structures that he sees there will reach their one-hundredth birthday, without practical rebuilding, much less their four-hundredth.

IT is common to excuse these imperfections of modern construction by saying that modern requirements demand a haste in building which is incompatible with solidity, and that, as American cities are, practically, rebuilt at least once in fifty years, it is not necessary to spend time and money in assuring the indefinite duration of a structure which, in half a century, at most, will be removed as an obsolete and valueless incumbrance to the ground. There is, of course, much truth in this, but the artist, if not the economist, finds difficulty in reconciling himself to the idea that his work will, perhaps within his own lifetime, be torn down, and consigned to the dump-heap, to make room for that of some more "up-to-date" person; and it is not impossible that we may find, as artistic feeling grows more general in this country, the best work devoted to comparatively unpretending structures.

THE Paris, Lyons and Mediterranean Railway has put in effect this summer a system of reduced-rate tickets which deserves imitation here. As this road connects Paris not only with the Mediterranean, but with Geneva and the mountain regions of Switzerland, it offers great attractions for people who wish to take their families to some pleasant seaside or mountain resort for the summer; and the railway company has undertaken to encourage the Parisians to give their families this pleasure by offering family tickets, available from the fifteenth of July to the first of November, between Paris and any station on the Paris, Lyons and Mediterranean system, at a reduced rate. The rate, for a family of three, going and returning, is equivalent to the price of five single tickets; that is, two of the family pay full fare both ways, while the third pays half fare. For a family of four or more, the price is again reduced, each person beyond the third paying one-half of the regular fare one way, or one-quarter of the full rate; so that a family of nine persons, for example, pays only four full fares. The well-to-do French are so fond of family trips that an arrangement of this kind is likely to be very popular; and the railway company adds to its attractions by providing that any one or more of the persons included in a "collective ticket" of this kind, on presenting a certificate which is furnished, on request, with the ticket, shall be entitled to travel between Paris and the destination named in the collective ticket, at any time while it remains in force, for one-half the regular fare; the object of this being, of course, to permit fathers of families, uncles or elder brothers, to attend to their affairs in Paris, or to make business visits, without too great expense. To make sure that these family tickets are used for the intended purpose, they are issued only between Paris and stations at a distance of two hundred miles or more; but, in order that prudent fathers of families may economize in their own travelling, without obliging their wives and children to journey uncomfortably, a person who takes a first-class "collective ticket" for his family may, after he has installed them comfortably in their seashore or mountain hotel, travel back and forth alone at half second-class fare.

RELATIVE PERMANENCE OF STEEL AND MASONRY CONSTRUCTION.[1] — I.

FORMAL papers, prepared with deliberation for delivery before an audience, or for publication in a periodical, are very excellent and desirable means for imparting information, but it is questionable whether, for the giving of information in an impressive and memorable form, they equal the more accidental method of *viva voce* discussion.

It is this belief that leads us to quote at length the discussion that our fellow-professionals the members of the American Society of Civil Engineers recently held on the ever-interesting topic of the lasting qualities of modern methods of construction.

CHARLES G. DARRACH, M. Am. Soc. C. E. — The speaker approaches this subject with some trepidation, as it is worthy of higher talent than he possesses.

To deal with the subject properly, there should be not only discussion, but contention and consultation, so that it may not be recorded among the dead by the epitaph which heads our publications: "This Society is not responsible, as a body, for the facts and opinions advanced in any of its publications."

The speaker would suggest that the subject be amended so as to read, "Is Metallic Construction, or the Combination of Metal and Cement Concrete, susceptible of being made as Permanent a Building Material as Masonry?"

Many years ago, the late Julius W. Adams, then President of the Society, suggested to the speaker that it was preëminently the business of the engineer to adapt the *motif* of his construction to the genius of the locality in which his field of operations lay. This is, in fact, the chief business of the engineer, and is using the best and cheapest means for the end to be attained.

It must not be forgotten, however, in making comparisons, that the best materials may be manipulated so as to produce inferior results, and the proper use of materials in composite engineering construction is as absolutely necessary as in the domestic arts, which please our palates, for it is well known that the cook can either spoil the pie or make the pudding.

Before determining upon a method of construction, there should be considered, not only the first cost, but also the expense of maintenance. The ease of inspection during erection should also be considered, as well as the adaptability of the material to obtain the most economical results.

A knowledge of the relative strength of the various materials, and also of the causes for deterioration and decay, should be attained. With this knowledge the problems will reduce themselves to some degree of simplicity. This knowledge can then be supplemented by observation and experiment, so that there need be no reason to fear results. Knowing the disease, the remedy therefor can be obtained.

The idea that masonry is the *sine qua non* of all permanent construction seems to the speaker to be without foundation. Permanence of masonry construction depends, not only upon proper design, but also upon perfect workmanship. All who have had any experience in construction know well that the most trying and difficult task of the engineer is to have masonry properly erected. In masonry construction, dependence must be placed upon the physical value of the stone, sand and cement. The stone, being a natural product, may or may not have that degree of permanence expected by the engineer, and, to meet this contingency, a large factor of safety is generally introduced in the calculations for masonry construction. Also, in many cases, where masonry is used, it is impossible to design the structure so that the economical quantities of material to meet necessary requirements can be used.

As has been intimated, masonry, as well as metallic construction, may be subject to deterioration and decay.

In using metallic construction, it is possible to calculate the stress upon the structure with a far greater degree of accuracy than can be applied to a masonry structure; consequently, the factor of ignorance can be reduced and the quantity of material used be nearer to that which is theoretically required. Inspection during construction and erection, and after completion, is more convenient, and, knowing the causes for deterioration, the necessary remedies and protection may be readily applied.

The use of concrete, or artificial stone, appeals to the speaker with much force. By its use artificial stone of equal value throughout the entire content can be obtained, and that value can be determined in direct accordance with the material of which it is made; so that the composition of the artificial stone can be adapted directly to the use for which it is intended. The cost of construction for equal values in artificial stone is generally much less than if natural stone were used.

Artificial stone, or concrete, forms a protection against the usual deterioration of metallic construction by atmospheric influence.

The logical conclusion seems to be that the best method of construction would be composite, using artificial stone and metal. Artificial stone, or concrete, not only forms a protection for the metal, but adds its value in resisting stress, and, except in subterranean and subaqueous structures the deterioration of metal encased in cement-concrete of proper composition may be disregarded.

There are many examples of structural metallic work encased in concrete where no deterioration is shown, even from ancient times. The modern system of iron construction encased in concrete or brick masonry, used in high office-buildings, shows that, when properly constructed, there is no observable deterioration in the metallic work. The Drexel Building, Fifth and Chestnut Streets, Philadelphia, was constructed in the years 1886–87. The speaker has removed portions of the ironwork in that building, and could see no deterioration whatever.

In the year 1891, the speaker made a cement floor and walk over a pipe-tunnel, the upper surface of which was exposed to all atmospheric influences. This floor was of cement concrete, about 4 inches in thickness, and had a span of about 5 feet. It was reënforced by bands of ordinary chicken-wire fencing, 16 inches in width, laid across the tunnel and spaced 16 inches apart. A bed of mortar, composed of cement and sand, about 1 inch thick, was laid upon a horizontal plank centre, and brought up flush with the top of the side-walls of the tunnel. Over this mortar the chicken-wire was laid, extending over the side-walls. The cement-concrete floor, 3 inches in depth, was laid upon this chicken-wire, and finished, the walk being about 7 feet wide. Although this walk has been in use for eleven years, no deterioration is apparent, nor has there ever been any leakage, even during the most severe storms.

In relation to this, attention is called to what the speaker considers faulty construction. The concrete floors of most office-buildings are of cement and ashes or cinders. The resultant concrete is not impervious. The large quantity of water used in construction is retained within the exterior skins of these floors for a long period, and, no doubt, is a detriment to the metallic construction of the floors.

In the year 1884, the speaker constructed a water-works well at Redbank, N. J. This well was some 15 feet in interior diameter, and was sunk from the surface of the ground to a depth of about 60 feet. The lower half, or 30 feet, was below the ocean level, and the entire well, to within 5 feet of the surface of the ground, was under the ground-water level. The water arose in the well to within 8 feet of the surface of the ground, so that the well-casing, 20 inches in thickness, constructed of hard brick laid in Portland-cement mortar, was continually in contact with water on both sides, and at times, even during construction, was under a pressure from the outside of more than 40 feet.

For reënforcing the brick shell during sinking, ¾-inch iron rods were extended from the cutting-curb upward through the masonry; and, at intervals of about 6 feet, large wrought-iron washers were placed over the rods and extended around the entire circumference of the well-casing. This construction was adopted to reënforce the green masonry of the casing during the operation of sinking. It would be interesting to examine this ironwork for the purposes of discussing this subject.

In the speaker's opinion, the hue and cry raised in relation to a properly constructed iron skeleton, in modern high buildings, is without foundation.

In buildings where the ironwork is concealed within fireproofing or concrete, there is little reason to suppose that any deterioration takes place, and the speaker will venture to state that, if the temperature and the humidity of the atmosphere immediately adjacent to the metallic structural work were observed and recorded, there would be found but little, if any, difference throughout the year.

Greater care, and concrete richer in cement, should be used for subterranean and subaqueous composite construction, and, in some cases, it would be advisable to use an asphaltic concrete, so as to absolutely prevent the possibility of any moisture coming in contact with the metal.

The numerous cases of electrolysis in subterranean metallic pipes suggest a criticism which has not as yet been presented to the speaker. Is it not possible that, in subterranean and subaqueous work, metal, even when constructed in cement concrete, may be subject to electrolysis similar to that experienced in metallic water and gas pipes? The speaker is of the opinion that all such subaqueous and subterranean constructions should be laid, as heretofore indicated, in an asphaltic concrete, and efforts should be made to force our legislators to pass laws preventing the use of the ground for an omnibus commercial electrical conductor.

We can also substitute for cast and wrought iron pipes a cheaper and more permanent conduit, constructed under the composite system. The capacity of metallic water-pipes is materially diminished by the formation of nodules on their interior surfaces, and, with some waters, the life of iron pipes is merely a question of a very few years.

Composite pipes, constructed of concrete reënforced by metal, can be constructed so as to have the necessary strength without the loss of conductivity due to the metal nodules, and it is not necessary that the concrete of which they are composed should be of such richness as to absolutely prevent at first the transmission of moisture, except when the liquid conducted is free from suspended matter. Conduits carrying either turbid water or sewage soon fill up the pores in the concrete, and make it impervious.

In 1894, the speaker constructed a septic tank for the Insane Asylum at Wernersville, Pa. The diameter of the tank was 25 feet, and the depth of water was 14 feet. The well was constructed of hard brick, laid in Portland-cement mortar, and had a maximum thickness of 21 inches. There was an inside coating of plaster, ½-inch thick, made of equal parts of Portland-cement and sharp sand. Tests were made through a period of ten weeks, at the end of which time masonry was practically impervious.

[1] An Informal Discussion at the Annual Convention, May 21, 1902, of the American Society of Civil Engineers and printed in the Society's *Proceedings* for August, 1902.

There is a paucity of experimental knowledge as to the strength of composite construction; the field is wide, of great importance, and deserves the attention and study of the members of our profession.

Before closing, the speaker would suggest that further experiment be instituted as to the possibility of making a metallic weld, to avoid as much as possible the use of bolts and rivets. He is aware that the electric weld does not give a resultant value of 100 per cent, but he is of the opinion that the Society would be gratified with a knowledge of the best results so far obtained.

EUGENE W. STERN, M. Am. Soc. C. E. — Discussing this question from the standpoint of the protection of iron-and-steel construction in buildings, the experience of the speaker is that iron does rust in buildings. That is, it rusts unless properly protected. Therefore, it is a very important question to determine what kind of protection it needs to prevent this, under different conditions of exposure.

In the interior of buildings, where there is no chance of moisture or acids attacking the iron, and where it is usually surrounded by fireproofing materials, the danger from rust is very slight. The usual coat of paint appears to give all the protection necessary.

The speaker has seen ironwork taken from the interior of buildings, in one case after thirty years, in which the shop-marks of white paint and the brown coat of red-oxide paint were in as perfect condition as if done but recently.

In the exterior walls of a building, however, and in the roof and cellar construction, it is an entirely different matter. A driving rain will go through the outer coating of brickwork; roofs will somehow or other leak, and cellars rarely are absolutely dry. The speaker has invariably seen evidences of rust on the ironwork taken from the above-mentioned positions in comparatively recent buildings. The paint seemed to have disappeared entirely in many cases where exterior brickwork was laid up against the iron. Where the mortar was in immediate contact with the iron, there was no rust; where the brick was directly in contact, there was considerable rust.

In a building in New York City, built in 1869, and now being taken down, cast-iron girders supporting the brick arches of the sidewalk construction were rusted about $\frac{1}{2}$ inch where the brick was immediately in contact with the iron, but where the mortar was directly in contact the iron was perfectly clean and black, looking as if taken from the sand only yesterday. The evidence that paint protects ironwork thus exposed, for any length of time, is not forthcoming. The paint seems to disappear entirely in a few years. Nor, in the speaker's opinion, does it help matters to prepare the surface of the ironwork, prior to painting, in the most painstaking and thorough manner, even using the sand-blast to remove the mill scale. Some of the paint is rubbed off the ironwork during erection, notwithstanding that the very greatest care is used. It is an inseparable condition, from the nature of the work, that this happens. There is then a starting-point for rust, and this will follow more quickly on a sand-blasted surface than on one having its mill scale.

The speaker is strongly opposed to the use of the sand-blast on ironwork for buildings. It does not help to protect iron permanently, and the expense, therefore, is not justified. For this reason the following method of protection is recommended: All the columns and girders in the exterior walls, the roof, the cellar, and wherever exposed to moisture or acids, should be surrounded with Portland-cement mortar, and the bore of the columns in such locations should also be filled solid with this mortar.

Broken stone in the mixture is not recommended, because the voids may not always be filled; and cinders are strongly objected to because there is good evidence to show their very harmful effect.

A building having its frame thus protected should remain structurally sound, judging from evidence, for many years, perhaps longer than one made entirely of masonry, unless of the best quality.

GEORGE F. SWAIN, M. Am. Soc. C. E. — People in general have come to consider iron or steel as rather perishable materials when compared with stone. Many persons form this idea by considering the old stone structures of the Greeks and Romans, notwithstanding the fact, referred to by one speaker, that there are a great many stone structures which have proved very perishable. Many instances can be cited of bridge-abutments built of sandstone or limestone which have practically gone to pieces within thirty or forty years. In judging of the ancient stone structures of Greece or Rome, we must also remember the difference in climate between those countries and Northern New England. It may not be out of place to point out also some differences between the ways in which steel and stone structures act. A stone structure is a comparatively simple one; it acts by its own weight; it acts generally in simple compression; its durability is a question of stability rather than of strength, and the loads may generally be increased greatly without endangering it.

A steel structure is very different. It is a complex structure, involving complicated stresses and strains; its strength is a controlling factor in its durability, and any increase of load reduces correspondingly its margin of safety. Engineers who have had much to do with questions of renewing bridges will agree with the speaker that cases in which bridges have had to be renewed on account of the actual wearing out of the material are comparatively rare. Of course, there are cases where corrosion is active, especially in bridges over railroads, but, leaving out such cases, the greater number of renewals which have taken place are due to other causes. One of these is defective design. Engineers are learning more and more every day in regard to the details of steel structures, and they are experimenting and studying the various connections and details. The result is that we find that structures built twenty or thirty years ago, and supposed to have an ample factor of safety, really had a much smaller factor. Moreover, as every one knows, the loads to which steel structures are exposed have increased enormously. These are the two elements which have caused the principal renewals of bridge structures. These elements will continue to be present, and, as long as they are present, we cannot hope to have steel structures in general as durable as the best stone structures would be. In the case of a steel-frame building, the loads, presumably, are not to change very much, and with good design the actual durability of the material should govern the life of the structure. As to what that durability will be seems very uncertain. All the engineer can do is to take every precaution he can to ensure the permanency of his steel. The speaker agrees with Mr. Stern that the steel should be completely enclosed in concrete, but, even under these conditions, he does not think the steel will last as long as the best masonry.

CHARLES C. WENTWORTH, M. Am. Soc. C. E. — The answer so far given to this question is that steel, when embedded in concrete to a sufficient depth, is permanent. A structure in which the steel is thus hidden becomes at times essentially as one built of concrete as of steel, and may be even more so. The fact that, in most cases, it is impracticable to adopt a composite construction, rather than one all steel or all concrete, renders it still necessary to seek a more complete answer to the question; especially if it be considered, as it must be, that bridges are made of "building material."

The answer given, for instance, is inapplicable to the East River bridges, built or building in New York City, and to the greater part, by weight, of ordinary railway-bridges. It is surely inapplicable to more structural steelwork, by weight, than it is applicable to all kinds.

The protection afforded by concrete is afforded by paint, but in a less degree. The objection to paint as an answer to the question lies in the fact that much structural work is inaccessible after erection, and that, in all likelihood, paint will not be applied properly or with sufficient frequency even where the work can be reached by the painter.

A more complete answer to the question appears to lie in the electro-plating of structural steel with copper or aluminium. This has already been done, to a small extent; but the subject does not appear to have received the attention it deserves.

The speaker sees no reason why such plating need be of excessive cost. Aluminium is an exceedingly abundant element, and is becoming cheaper; copper may retain its value. Metallic aluminium may not be needed in the process, but such aluminium salt as will serve when in solution as the source of the metallic aluminium finally composing the plating.

Of course it would be impracticable to plate steel as it comes from the rolls, as rivet-heads and sheared edges would need subsequent plating; but each structural piece, ready for shipment and erection in the structure, could be plated, and the details of field-connections arranged with a view to their permanency on the same lines.

The speaker does not wish to appear as objecting to the use of concrete structures stiffened by steel, with the incidental protection afforded to the steel by the concrete. Such structures are entirely proper and appropriate in very many cases; but, in conclusion, he wishes to say that the plating of structural steel, as a more general answer to the question, is well worthy of the attention of the members of this Society.

OBERLIN SMITH, M. Am. Soc. C. E. — The speaker is not experienced in putting up big steel buildings, but it seems to him that a certain precaution should be taken, which, perhaps, usually is not, and which will be mentioned later. Some of these buildings have been up a good many years and seem to be very strong, but after this generation is gone — fifty or one hundred years hence — if there is no way to examine all that hidden metal inside the masonry, how are people going to feel about the stability of such buildings? When will the time arrive for them to come down of themselves? There should be, therefore, some systematic method of examination.

Of course, after many years, the owners may tear out some of the masonry and examine the steel, but it would be a small matter now to provide inspection holes, properly covered, and to differentiate and classify the various conditions of possible deterioration to which the metal may be subjected.

Certain parts of the building which are most likely to rust, and where such rusting is most likely to cause accidents and damage, would be in one class, while other parts which are not so likely to be affected would be in another, and so forth. In every building, in several proper locations, let there be certain places left where the metal can very easily be exposed, and again covered up — of course in a fireproof manner. This would be done instead of merely tearing away a building at random, with perhaps considerable damage and with consequent expensive repairs.

To find out how the steel is really getting along, there should be certain times for observation, with definite intervals between. These intervals might be five, or ten, or twenty-five, years — as experience should dictate. The most risky "classes" should be examined the oftenest. In general, there should be certain definite methods of inspection, and definite places for inspection, and definite times for inspection of this buried and perhaps much-suffering metal, not only that such may be done with less damage to the building, but that it

may be done thinkingly and systematically — instead of waiting for some Chicago post-office to become obsolete that we may see whether it continued safe until the end. If not done in such a manner all may be neglected, and intervals which are uncertain may become of infinite length.

WILLIAM R. WEBSTER, M. Am. Soc. C. E. — The examination of many old bridges and other structures has shown that the white-lead marking-letters of the mill are intact, and that the metal is better protected at these places than at others. That is, the plates and shapes are generally marked while hot, and before the material has had a chance to rust; but the full importance of applying the protective coating while the metal is hot has not been appreciated.

The ordinary oiling at the mills has not been satisfactory, as the material is generally made sticky and difficult to handle in the shops. In relation to this, attention is called to a railroad spike dipped in oil, while slightly heated (in accordance with the specifications for an export order). Under this treatment the oil quickly dried and formed a good hard protective coating. This process might be applied to ordinary structural shapes and plates with great advantage; the material being cleaned with brushes and an air blast, and the oil applied while the material is still hot, the coating in no case being heavy enough to interfere with a thorough inspection for surface defects. The shop painting, of course, should be applied in the usual manner.

JAMES OWEN, M. Am. Soc. C. E. — It might be interesting to know that, in endeavoring to find some records of the strength of concrete beams, the speaker found, in the library of the Society, the report of some experiments made by Mr. Kirkaldy in 1854. Mr. Kirkaldy at that time had made an elaborate investigation of the strength of the admixture of concrete with iron rods and iron wire. Results showed at that time that the strength of the combination of the two materials, iron and concrete, was increased by more than two and one-half times that of the simple concrete itself. This is quite in accord with the present experiments in that line, and it is interesting to note that while these investigations were made so many years ago, it is only of late that the profession has appreciated their importance.

The speaker had a peculiar experience in relation to the strength of an ordinary bridge built with iron beams and brick arches and covered with concrete. The span was 15 feet. The bridge had been built some eight or ten years when the local engineer decided to change the grade of the street, and raised it about 6 feet. This alteration imposed on the bridge itself an extra load of 900 pounds per square foot. That, with a previous allowance of 200 pounds, made a total of 11,000 pounds. The bridge was originally designed for a live and dead load of 300 pounds and a factor of safety of four. A critical examination of the bridge, after the extra load had been on about six months, showed no rupture of any kind and no apparent deflection. The bridge is still in use.

It may be presumed, therefore, that the combined use of steel and concrete is susceptible of a great deal of further development, and that its ultimate strength is apparently unknown.

E. T. D. MYERS, JR., M. Am. Soc. C. E. — During the summer of 1901, a rifle-barrel was pumped up through the 20 inch pipe connected with the centrifrugal pump which was used in dredging out the historic dock immediately in front of Libby Prison. It arrived at the usual joint, just in front of the pump, which was intended to stop obstructions too large to pass through the pump. The pump was stopped and the rifle-barrel taken out. It was found that the blue enamel on the barrel was intact on at least 90 per cent of its surface, and the sight could be raised and lowered without the slightest difficulty. The date on the barrel was 1856. It was probably thrown in the water in 1865.

The water there is fresh, and is entirely free from lime. It is what is known as a "kind" water for boilers. The speaker does not know whether metal would last that way in other waters, but he has pumped up and dug up shells and rifles which were not rusted.

The depth of water in the dock was originally 16 feet, and the depth of the silt was about 4 feet. The pump was working at a depth of 22 feet. It is impossible to state the depth at which the rifle lay, but it probably came from the 16-foot level. The bottom is composed of sand and gravel, and the silt lying upon it came from the James River, which runs through a red-clay country. The rifle-barrel, therefore, had about 16 feet of mud and fresh water above it.

The speaker does not feel competent to discuss this topic, but he is deeply interested in it, and hopes that the result of the discussion will be the addition of much valuable information.

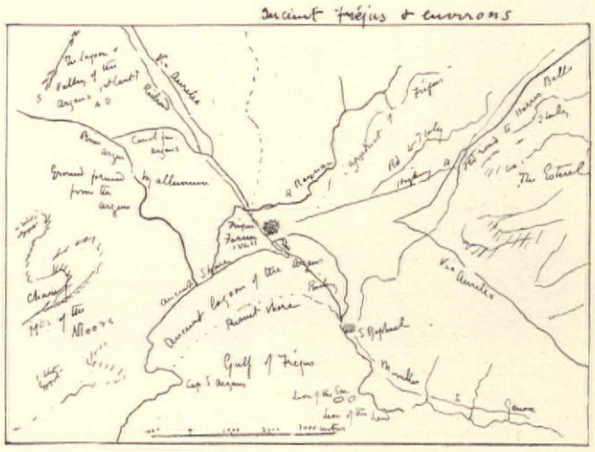
[To be continued.]

THE BALL-ROOM IN THE MELBOURNE GOVERNMENT HOUSE. — In the opinion of Mr. Shields, the new Australian Treasurer, Australians are nationally and individually an extravagant people. He proves it with an anecdote. When the present huge Government House in Melbourne was being planned, the architect consulted the Premier of the period as to the size of the ball-room. "Do you know anything about ball-rooms in other parts of the world?" queried the Premier. "I only know the one in Buckingham Palace," was the reply. "Then build our ball-room a third bigger than the one in Buckingham Palace." It was done as the lordly Premier commanded, and so Melbourne came to possess the biggest ball room in the world. — *N. Y. Tribune.*

ROMAN AND ROMANESQUE FRANCE.[1] — III.

FRÉJUS.

WHEN the Chancellor Michel de l'Hôpital (1505–73) was travelling in the South of France, he composed a letter to his friend Jacques du Four de Pibrac, in Latin verse, as was his wont, being a scholar devoted to elegant literature. "We come to Fréjus,"

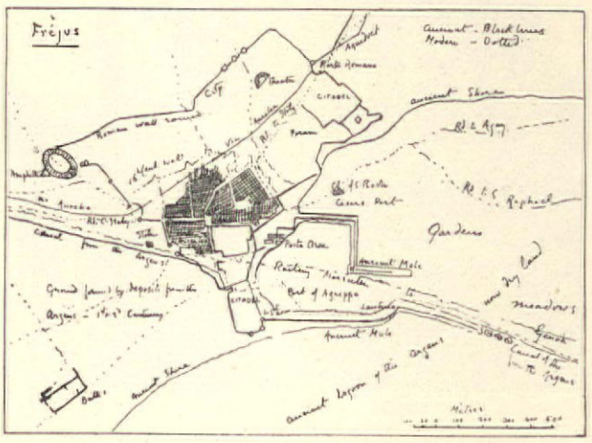


he says, "which is now only a poor small town. Here are the ruins of the old theatre, the broken arches, the baths, the aqueduct, and the scattered remains of the quay and basins; the port has disappeared beneath the sands, and in its place there are only the beach and the fields." Such as it was in the sixteenth century so it is now — dead of the mud and alluvium of the river to which it formerly owed its existence.

The earliest colonists were the Phœnicians and Phokean Greeks. Agricola, the father-in-law of Tacitus, calls it an illustrious and very old colony; Cæsar called it *Forum Julii Decumanorum*, and it became an important port on the Via Aurelia.

After the death of Cæsar, confusion reigned in the Empire. Antony was in the Alps, while Lepidus was governing Provence; hence, they were opposed to each other; and in a letter written by Marcus Lepidus to Cicero we get an idea of the state of affairs as Antony drew near to Fréjus: "I have learned," he wrote, "that Antony is advancing towards my province at the head of his army. . . . I have left the confluence of the Rhone, and have come by forced marches as far as Forum Vocanii [24 miles from Fréjus]; I have encamped my troops a little beyond it, near the river Argens." . . . Plaucus adds, saluting Cicero, "I have heard that Antony arrived at Fréjus with his vanguard about the ides of May." Later the two commanders met and formed a project for uniting their forces and sharing the spoil, the place of meeting being the bridge of Argens, the remains of which were standing only thirty years ago, when the three unequal arches were carried away by the sudden rise of the river, leaving only some portions of the abutments.

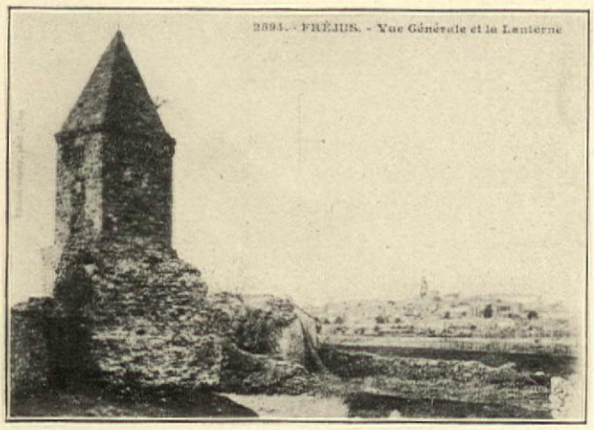
When the railway from Toulon to Nice was being constructed, excavations had to be made upon the alluvial land which was once the port of Fréjus; many inscribed stones were brought to light and *a few saved*, most of them being destroyed by the workmen. One, evidently a *cippus*, seems to have been a pedestal for a statue or vase. The beautiful letters of the inscription date it about the



second century B. C. The inscription is bilingual, the dedication being in Latin, the pathetic epitaph in Greek. "To Caius Vibius Ligur, his mother Maxima. This tomb was built for those who were older; but destiny has struck, under the influence of the climate of the country, a child seven years old. His relations, his father and

[1] Continued from No. 1394, page 86.

his mother, have buried him whom they had brought up. . . . Oh, the vain hopes of men here below." But the mass of ruins are of the period of Imperial Rome, subsequent to the conquest of Gaul, and it is sad to relate that the greatest destruction has taken place



General View of Frejus and the Lantern.

recently, as is proved by a description of them in the Abbé Girardin's "*Histoire de la ville et de l'église de Fréjus*," 1729. Even as late as the year 1829, the ruins were in a better condition than they are now (see "*Memoires sur la ville et le port de Fréjus*" by Ch. Texier, 1849); but the modern archæologist (and what architect is not an archæologist?) can still trace the extent of the Roman city and port.

The town had four gates: the Porta Gallica, Porta Romana, Porta Argentea and Porta Oræ, called incorrectly Aurea and Dorée in modern times. Built of regular courses of red sandstone, porphyry and brick, it is of later date than the rest of the town, and formed part of a large portico giving access to the quay, and openings onto the lagoon, which in old French was called (scarcely three centuries ago) *l'orée*, a word derived from *ora*, border, shore (Leuthéric). Joinville used it in his life of St. Louis, "avait fait tendre

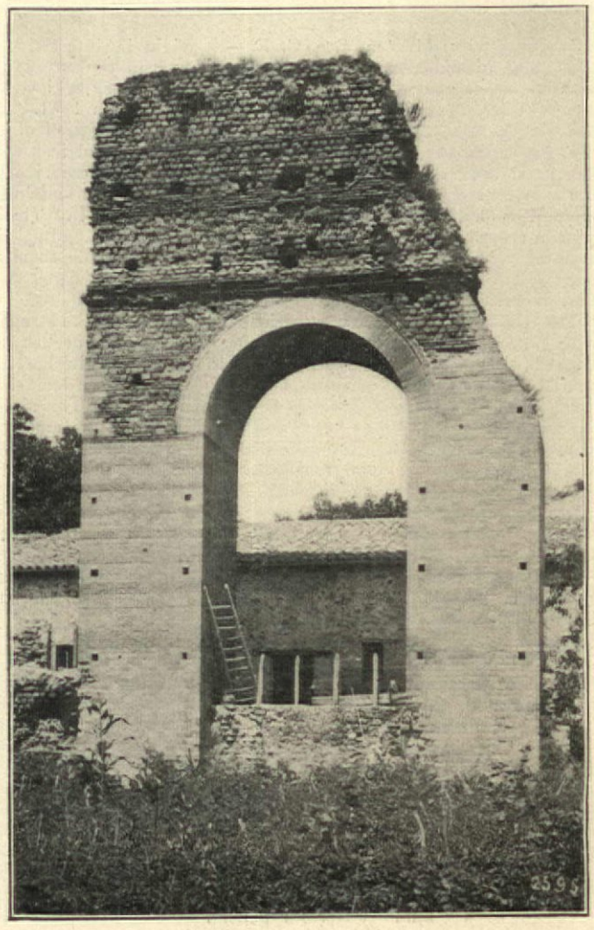
Portion of Aqueduct, Frejus.

ung pavillon sur l'orée du fleuve"; and Rabelais — "Les porte-guidons et porte-enseignes avaient unis leurs guidons et enseignent l'orée des murs." Thus, the theory that it was called Porta Dorée by reason of the richness of the merchandise which passed under it is pure fiction.

Shapeless ruins at each end of the town represent the citadels which frowned upon the harbor, now but a sandy plain interspersed with stagnant pools and efforts towards cultivation. Across one of these fields is the "light-house," so named upon D'Auville's map, but without a snap of evidence to prove that it was ever hollow in the interior. On the contrary, it is quite solid and is thought to have been a sea-mark, the summit of the pyramid being used for a vane or flagstaff. It has a circular base, surmounted by a six-sided prism, on the top of which there is a hexagonal pyramid; and it is possible that the faces of the prism were utilized, like those of the Tower of the Winds at Athens, as sundials; the vane at the summit, indicating the direction of the wind, and thus acting as a guide to vessels entering the port. It is in a perfect state of preservation and marks the end of the great Roman pier. "It is interesting," says M. Leuthéric, "to observe that one of the oldest Greek poets, Leschês, who lived some 630 B. C., describes in his '*Ilias Minor*' a tower of the same kind, which stood at the extremity of the promontory of Sigeium, on the Hellespont, at the time of the Siege of Troy."

The real pharos of Fréjus was opposite, and was constructed very much after the model of the one at Alexandria. It was, unfortunately, destroyed by an earthquake in 1303.

The great principle of the Roman governors as regards building was to give employment to their soldiers in time of peace. Hence, the style of architecture adopted from the Etruscans, the piling up



Roman Ruin, Frejus.

of huge masses of hewn stone without cement and the employment of the arch ceased with the Republic, and in the colonies buildings were constructed of rubble held together by cement. This style of building could be done by any able-bodied men, were they soldiers, prisoners of war, slaves, convicts or freemen.

Fréjus is an example of this style of building. It was done quickly — the whole town, walls, quays and gates were erected in the same manner and of the same material; and though blocks of stone could have been found in the neighboring mountains, this would have required time; so the whole place was built of brick and rubble faced with marble casings and decorations. If a rock came in the way, it was utilized and built in, as was the case in the Amphitheatre, half of it being a mass of volcanic rock. Everywhere there is evidence of speed, and the practical desire of turning everything to advantage.

The greatest wisdom was displayed by the Romans in their water-supply; wherever they passed, we find the remains of aqueducts. Pure water was as necessary to them as pure air is to us. The modern practice of depending upon rivers and wells, in the towns the former frequently sewers as well as drinking-fountains, was unknown to them. At Fréjus a little river some 37 miles off, the Siagne, was diverted across an aqueduct for the supply of the town

— the ruins may still be traced. Part of the way it was a subterranean conduit, the water coming in at the level of the ramparts, and passing under flagstones which encircled the town. The arches had a span of 5 metres, and were 10 or 12 metres high. In some parts a second channel had been made, showing that the first, being constructed too rapidly, had given way.

The remains of the Amphitheatre are sufficient to enable us to judge of its exact dimensions. It is elliptical, 113 metres at the greater, 95 metres at the lesser axis; the arena being 61.71 m. x 39.6 m. It may thus be surmised that the population of Fréjus was about 20,000 to 25,000 persons.

After the Roman occupation had ceased, the town fell into decay, barbarians and Saracens joining in its destruction. The arena became a fortress, and the bishops of the tenth century, in building up a new wall, used up all the old material they required. The port silted up like those of Ravenna, Ostia, Aigues-Mortes, and one of England's Cinque-ports, Sandgate; and now one walks over market-gardens and fields where the 300 galleys cast anchor which were captured by Octavius Cæsar at Actium. S. Beale.

Books and Papers

Mr. Hodgson is very well known as a writer of practical manuals for mechanics, which have had an extensive and well-deserved circulation. The present little work,[1] although less pretentious than its name might perhaps imply, is really modern, and should prove useful to a large number of readers. The first division, which treats of "Carpenters' Geometry," would be improved by more scientific precision, as where an "equilateral triangle" is defined as "a polygon having three sides," omitting the word "regular," or in the description of the ellipse; but the problems given in illustration are well chosen, and ambitious young men will have no difficulty in taking up, later, more scientific and comprehensive treatises on descriptive and applied geometry.

It is, perhaps, inevitable that practical treatises of this sort should seem to the instructed reader rambling and disconnected, jumping suddenly from the geometry of triangles to that of conic sections; from this, again, to problems in descriptive geometry of a tolerably complicated character, and winding up with observations on balloon-framing; but Mr. Hodgson understands thoroughly the experiences of the young mechanic, and is sensible enough to sacrifice smoothness of form for the sake of collecting the solutions of as many every-day difficulties as possible in a single small treatise; and, although not very much can be said about roof-trussing and stair-building, and making compound beams, and balloon-framing, and joinery, and centring, in one small book, which has to contain, in addition, a hundred pages of geometry, what is said is, in most cases, exactly what the young builder needs first to know, and the author refers his readers, where he thinks it necessary, to books from which further information can be obtained. We doubt whether the profession will quite agree with Mr. Hodgson, that "Architects say that the exact measurement for a tread and riser should be 16 inches, or thereabouts." Seventeen to 18 inches would be nearer the mark, and most architects, instead of adding the tread and riser together, multiply them, and take a product between 70 and 75 as limits. This is, however, a detail, in regard to which local customs may vary, and a mechanic working from an architect's plans is, of course, guided by them.

Notwithstanding these trifling criticisms, Mr. Hodgson's little book is one which every young architect, as well as every young mechanic, will find very useful. There is a common notion among draughtsmen that they need not trouble themselves about details of construction, but this is not the opinion of the most distinguished architects, who are generally noted for their ingenuity in mechanical as well as artistic points. Mr. R. Norman Shaw, as thorough an artist as the profession in England has ever possessed, patented, we believe, an improvement in soil-pipes, and Wren was famous as a mechanic. Without attempting to rival these masters, the young architect will find it valuable to him to be able to show the men who work under him, in case of need, how to "saw in" a base-board to fit neatly around a curve, or how to mitre a raking moulding, or a hundred other things which, without his intelligent direction, would be discreditably botched; and in regard to such matters Mr. Hodgson's book gives a great many suggestions, which can soon be learned, and are likely to come frequently into use in the daily work of the young architect, assistant or superintendent.

Memorial Window in Westminster. — When Westminster Abbey was reopened for public worship on Sunday, October 5, the magnificent new rose window which has been placed in the south transept as a memorial to the late Duke of Westminster was seen in all its beauty. Its cost has been covered by a public subscription, which amounted to nearly £2,400. The general subject is "The Preparation of the World for the Great Day," and there are twelve lower lights representing the early Christian preachers and martyrs. The design is by Mr. G. F. Bodley, A. R. A., and the colors chosen are much brighter than those of the old window, in order to improve the light in the rather gloomy Poets' Corner. — *London Telegraph.*

AN OLD BUILDING-CONTRACT.

New York, N. Y., October 4, 1902.

To the Editors of the American Architect: —

Dear Sirs, — I came across an old building-contract in my grandfather's account-book and enclose herewith a copy, thinking it might be of interest to your readers. Very truly yours,

C. R. McNeil.

Know all men by these presents that I, Salmon Hummiston, of Harwinton, in the County of Litchfield and State of Connecticut, am holden and firmly bound unto Isaac McNeile of Litchfield Town and County aforesaid in the sum of £100 lawful money for which payment well and truly to be made to the said Isaac McNeile, his heirs, executors, administrators or assigns.

I the said Salmon Hummiston bind myself, my heirs, executors and administrators firmly by these presents sealed with my seal dated the first day of November A. D. 1794.

Whereas the above bound Salmon Hummiston hath this day agreed to do the inside joiner work to said Isaac McNeile's new house standing in said Litchfield, Northeast farms and to compleat the lower part of the old house which joins the new one and to finish the chamber flower and stairs of said old house.

Said new house is to be done in the following manner, to wit, in a good, genteel, fashionable manner. The lower South front room to be done in the following manner, to wit, with a good, decent breastwork around the chimney, with cupboards and closets as many as is necessary, with a mop board, chair rail and a cornish spring around the room and wainscot doors and to be lathed fit for plastering.

All the other rooms above and below to be done in the same manner except between the bedroom and kitchen which is to be ceiled on the kitchen side and lathed on the other.

The chamber to be done in the same manner.

The doors of the North room and North chamber to be made with six panels and all the other doors with four panels and good stairs from the bottom of the seller to the top of the garret and all the garret floors to be laid.

Said Isaac is to find the stuff necessary for the completion of the house, and to board said Salmon while doing said house, and said Salmon is to come any time with a fortnights warning. Said work to be compleated by the first of December A. D. 1795. The windows to be well cased all below the garret.

The said Isaac is to give said Salmon Thirty Pounds and Six Shillings. Six pounds of said sum to be paid in cash when the work is done, the remainder to be paid in neat cattle or grain, bulls and stags except one half of said sum to be paid when the work is done, the other half the following fall.

The condition of the above obligation is such that if the above bound Salmon does in all things well and truly keep and perform in manner and form as above written according to the true intent and meaning of the above parties the above obligation to be void, otherwise to remain in full force and life.

Signed and sealed in presence of
WILLIAM BARTLOW, }
ISAAC MCNEILE, JR., } SALMON HUMMISTON.

THE NEW YORK ART COMMISSION AND THE STREET-SIGNS.

NEW YORK, N. Y., October 6, 1902.

TO THE EDITORS OF THE AMERICAN ARCHITECT: —

Dear Sirs, — My attention has just been called to your editorial on page 66 in the issue of August 30 of the *American Architect*, and I am led thereby to call your attention to the fact that the Municipal Art Society is a body entirely diverse from the Art Commission of the City of New York. The Charter of the City of New York gives no powers to the Municipal Art Society, but does give definite powers to the Art Commission, of which I have the honor to be a member appointed by Mayor Low. Under the Charter it was not necessary for the street-signs to be referred to the Art Commission, but the Mayor or the President of the Board of Aldermen had the right so to do, and they took such action, for which reason the matter of the street-signs has been before, and has been acted upon by, the Art Commission. Yours truly,

HENRY RUTGERS MARSHALL.

NOTES AND CLIPPINGS

THE CUNEIFORM TABLETS FROM NIPPUR. — Professor Herman V. Hilprecht of the University of Pennsylvania, who has been abroad a year and a half engaged in excavating, at the cost of the University, the buried city of Nippur, in Babylonia, has returned to Philadelphia. Professor Hilprecht believes the University expedition has accomplished the most important work so far done at Nippur. "We have unearthed 23,000 tablets," he said, "and I shall make the deciphering of them my life-work. The contents of these tablets will change the ideas of the world as to the state of civilization and knowledge of the early Babylonians. It will be seen that they knew in 2,300 B. C. that the earth was a globe, and that their astronomers took the same view of celestial phenomena as we now take. The inscriptions are in cuneiform characters. Their deciphering is a matter of much difficulty, for we have no Babylonian alphabet; we must not only translate, we must discover the alphabet, which is the key to the translation. Nippur is, in fact, sixteen cities, one built above the other. We have by no means reached the lower of these buried cities. Much of the temple library has been brought here, and is now in the museum of the University. Within the last four months our most important discoveries were made." — *Boston Transcript.*

THE TEXAS MISSION BUILDINGS. — A movement is on foot among the public-spirited women of Texas to preserve to posterity the old Missions of that State, which are fast falling into ruin. Daughters of the Republic of Texas they call themselves, and the various cities have chapters which devote themselves to local work, after the fashion of local chapters of Daughters of the Revolution and Daughters of the American Revolution in the North. The De Zavala Chapter, of San Antonio, is one of the most active of these, partly through the personal initiative of the president, Mrs. Adina de Zavala, who is most enthusiastic over the noble historic and artistic works of the self-sacrificing Franciscans, and partly because San Antonio is peculiarly rich in these interesting remains. Of the five Missions in the vicinity of San Antonio, one — the San José Mission — dates from 1690 and is considered the most beautiful on the continent. The carvings are by the artist Huicar, who was imported from Spain for the purpose of decorating the church. The façade is rich to repletion with virgins and saints, cherubs, sacred hearts, pedestals, canopies and cornices, while one of the windows in the baptistery is said to be the finest gem of architectural ornamentation in America to-day. Among the prominent persons interested in the preservation of these old ecclesiastical buildings is Miss Helen Gould. Miss Gould has expressed her interest by a handsome gift of money to the De Zavala Chapter. — *N. Y. Tribune.*

RESTORING THE FRESCOS ON THE PINAKOTHEK, MUNICH. — One of the uses for which the money recently refused by the Bavarian Parliament to Prince Luitpold is urgently needed is the restoration in some manner of the famous frescos by Kaulbach, Cornelius, Piloty, and other noted artists that adorn the Pinakothek and the Maximilianeum of the Bavarian capital. As all visitors to Munich have observed, these frescos, exposed as they are to one of the worst climates in Europe, are rapidly disappearing. After consultation with the best experts, the Bavarian Government has decided to reproduce these cartoons in mosaic so far as this is possible, and a beginning is to be made with those by Piloty. The cost will be something like $250,000. The offer of Kaiser Wilhelm to pay part of the expense out of his own pocket has so aroused Bavarian resentment that there seems to be no doubt about the money being forthcoming from private subscription should the Parliament persist in its refusal to contribute. All artists are agreed as to the necessity of prompt action. — *N. Y. Evening Post.*

THE "GRACES" ON THE NEW PALACE, POTSDAM. — The New Palace, says the London *Chronicle*, where the German Emperor entertained his distinguished manœuvre guests, is only "new" in the sense that New College, Oxford, is so; that is to say, it was new when it was built, about the close of the Seven Years' War. Frederick, whose Potsdam residence had hitherto been Sans Souci, determined to construct it to show his enemies that his finances had not been exhausted. The chief of these enemies were three women — Maria Theresa, the Empress Elisabeth and La Pompadour — and when his new palace was finished, Frederick, with bitter mockery, surmounted it with a crown supported by the nude figures of these three illustrious ladies, each with her back turned toward her own country. They are there to this day. Emperor Frederick, who was born and died in the palace, renamed it "Friedrichskron," though one of the first things done by his son, on succeeding him, was to decree the restoration of its old title.

DISCOVERY IN THE ROMAN FORUM. — Two tombs of great antiquity have been discovered in the Necropolis in the Forum early in the month of October. — *Exchange.*

HOUSES CARRIED SEVENTY MILES ON FLATBOAT. — While doing a bit of surveying in East Camden, N. J., Assistant City Engineer Sayrs was surprised to find on a lot which was vacant on his last trip to that section two frame houses, 15′ x 24′, and three stories high. They were situated in Buren St., between Twenty-seventh and Twenty-eighth Sts., about 300 feet from the river. Having received no report from the city-clerk's office of a permit for the erection of the houses, and knowing that it was an impossibility to have built them in the time after his last visit, Mr. Sayrs knocked on the front door of one of the houses. A German responded, and in answer to questions said that he and a fellow German, who owned the other house, had removed them to this city from Reading, Penn. A flatboat, he said, was used in transporting the houses down the Schuylkill, into and up the Delaware, a total distance of about seventy miles. — *N. Y. Tribune.*

THE CATHEDRAL OF GOTHENBURG. — The Cathedral of Gothenburg, "the Swedish Venice," which threatens to share the fate of the Campanile, is only a hundred years old. It burned down in 1721 and again in 1802. — *Exchange.*

SPONTANEOUS COMBUSTION OF SOOT. — A recent incident which occurred in Macon, Ga., shows the great danger from spontaneous combustion and how it will sometimes develop under the most unexpected circumstances. The soot and other refuse which had accumulated from cleaning a tubular boiler was thrown into a pile outside the boiler-house. A few hours later it was found to be on fire, and had it not been discovered in time would have set fire to the building. Upon investigation it was found that there could not have been any fire near the soot, but that there had been a slight rain followed by several hours of bright sunshine. The heat of the sun's rays aided by some chemical action in the soot itself must have caused spontaneous combustion. — *Fire and Water.*

VENETIAN WORKS OF ART. — In the province of Venice there are 1,111 art-works under the guardianship of a special committee, which however, has at its disposal only 13,500 lire, or about $2 a year for the preservation of each monument! — *N. Y. Evening Post.*

VENTILATION IN TUNNELLING. — For every cubic foot of air that was sent into the St. Gothard Tunnel a quarter of a century ago, 50 cubic feet are being introduced into the Simplon Tunnel. The mortality, in consequence, is much lower. — *Exchange.*

NOTES AND CLIPPINGS. 23

THE Boston *Herald* makes some judicious observations on the report of a committee of British manufacturers, who recently visited this country, to ascertain, if possible, the causes of American success in taking away the iron trade from them. The committee found that the chief cause of the superiority of the Americans lay in the excellence of their machinery, which, by enabling a man to accomplish an immense amount of work, reduced the labor-cost on the product. Thus, they found that, in rolling steel bars, so much is now done by machinery that the labor-cost, per ton, is only a small fraction of what it was ten years ago; and, in making rails, beams and other shapes a similar reduction in cost has been effected. All this is, undoubtedly, as true as it is interesting, but the *Herald* asks, very pertinently, who it is that gains by the introduction of all this labor-saving machinery. It is certainly not the consumer, who, in this country, pays more for his rails, or bars, or beams, than he did ten years ago, when, as we are told, the cost of making them was far greater; and the *Herald* concludes that the saving is all diverted into the pockets of the manufacturers, who are enabled, by means of it, to pay interest on vast issues of speculative securities, the sale of which has served to enrich a good many people, and, we hope, will not serve to impoverish a good many more. Undoubtedly, it is fair enough that the people who introduce economies in their processes and machinery should profit by them, but the natural course of events is that the competitors of the people who first introduce them invent new economies, to enable them to compete for customers with their rivals; and, in the end, the public gets a reasonable share in the advantages secured by such improvements. In many branches of American industry this has been the result, and it is probable that a falling-off in the demand would reduce in the same way the cost of iron. Meanwhile, it is due to the management of the United States Steel Company, which, as the largest and most conspicuous manufacturing corporation in the country, receives a good deal of abuse which is quite misdirected, to say that its policy has always been, not to take advantage of the necessities of its customers to extort high prices, but to keep prices down to a moderately remunerative point; and this policy, pursued with discretion, ought to save it from the violent shocks which are as disastrous, in the end, to consumers as to producers.

ALTHOUGH the great coal-strike seems in the way of settlement, through the intervention of Mr. J. Pierpont Morgan, it is likely that a measure for the repeal of the duty on coal, which the Administration is known to favor, and which is supported by a strong popular sentiment, will be carried through Congress in December. Whether the repeal will result in any large importation of anthracite depends on the price of the Pennsylvania product; but there is a great deal of anthracite in the world, in France, Germany, Wales, Scotland and Canada, and high prices, with the duty removed, would undoubtedly attract it here. Even if the "round coal" could be brought to our seaport towns more cheaply from Pennsylvania, it is not impossible that a traffic might be built up in the "boulets d'anthracite," which are made in France and Germany of the dust from the anthracite mines, and are sold very cheap. The people of New England, in particular, seem to have become convinced of the fact that they are not fairly treated in the matter of fuel, and are likely to be more open in future to propositions for a better and cheaper supply than they have been hitherto.

SO many people have made inquiries of us in regard to the Massachusetts and Rhode Island anthracite that it may be of interest to give some further information. In all, twelve mines have been opened into this anthracite bed, which covers an estimated area of five hundred square miles, including the whole State of Rhode Island, and extending into Massachusetts as far as Worcester. The coal varies in quality from that found in Mansfield, which contains only four per cent of ash, to the deposits at Worcester and Providence, where it is in great part converted into graphite, so that the product of a mine now worked in Providence is said to be ground up and sold for stove-blacking and lubricating paste. All the mines in Massachusetts, consisting of three in Mansfield, one in Wrentham and one in Raynham, have been abandoned, but one of the mines at Portsmouth, R. I., has been worked intermittently for many years. From this mine seven hundred and fifty thousand tons of coal have been produced and sold; and the quality of the coal was for a long time regarded as so good that it brought a higher price, at the mine, than any other anthracite in the United States. Early in the history of the mine, the Portsmouth coal was sold, at the mine, for five dollars a ton for "round" coal, and half that for the "slack," but this was soon reduced to three dollars for the round coal, or coal in lumps, such as is used for domestic purposes, and fifty cents to a dollar for the slack, and at these prices the operation of the mine was found for many years profitable. It appears that the discouragements attending anthracite mining, both in Rhode Island and Massachusetts, have not come from any inferiority in the quality of the coal, but from the irregularity of the veins, which, though thick, reaching twenty-three feet in Mansfield, and thirteen in Portsmouth, vary greatly within short distances. Whether these irregularities would make it impossible for the New England mines ever to be permanently worked with profit on a large scale, in competition with those of Pennsylvania, is uncertain, but the fact that one of them, at least, has successfully met that competition for half a century, and that the quality of the coal improves with the depth of the vein, suggests, at least, that at the present time, when the price of Pennsylvania anthracite in New England and New York is about three times the average for the last twenty-five years, and is likely to remain far above that average for many months, an effort might be profitably made to extend the workings, and introduce the economies incident to operation on a large scale, so as to render New England permanently independent of Pennsylvania anthracite.

THE old Hall of Records in New York is to be taken down immediately, by order of Justice Leventritt, of the Supreme Court, on the application of the Corporation Counsel. The building is close to the excavation of the new rapid transit subway, and the sand on which its foundations rest is in danger at any moment of escaping into the subway trench, so that its removal is a matter of necessity. Although it has some historical interest, the structure is of no value otherwise, and would soon be superseded by the new Hall of Records, now building. Meanwhile, it is a disfigurement and encumbrance to the City Hall Park, and would be better out of the way.

PROFESSOR KEUSSMANN, of the Wilhelm-Gymnasium, at Hamburg, delivered an interesting lecture recently before the Society of Architects and Engineers of Hamburg, on the Roman Campagna. Every one knows that this district, now the reproach of Italy for its deadly malaria, was, in antiquity, a beautiful and healthy region, filled with farms and

Entered at the Post-Office at Boston as second-class matter

villas. The change to its present condition has been ascribed to all sorts of mysterious moral, as well as physical, causes; but Dr. Keussmann says that the simple solution of the mystery is that, in the times of the Roman Republic, the land was carefully drained by means of a network of underdrains which still remain. In some places, where the ground was naturally unfavorable, four sets of pipes have been found, one above another, the lowest being more than fifty feet below the surface. Under the Empire, the system of farming in Italy, as all students of history know, was gradually changed. The small estates, kept in good condition by thrifty freeholders, were gradually bought up, and consolidated into vast "latifundia," or ranches, owned by great city capitalists, and cultivated by slaves, under the charge of an overseer. It is impossible to carry on with slaves the diversified and careful tillage which small proprietors find profitable, and the "latifundia" sank into the condition of our Southern plantations under slavery, all the more enlightened details of the system of farming formerly pursued being neglected. The drains, which the slaves knew nothing about, and their overseers cared nothing about, were allowed to choke with mud, and the ground soon became as saturated and foul as ever. As crops could not be grown in water-soaked soil, the more marshy portions were devoted to pasturage, and the few remaining people of intelligence fled from the increasing malaria. It is curious that, even now, although fifteen hundred years of misery have made the name of the Campagna a synonym for wretchedness and crime, its condition is worse, perhaps, than ever, and from the same causes. The present proprietors of the land are still, for the most part, the members of the noble Roman families, who display about the same business energy and interest in their property that the Senators and courtiers who preceded them did. In order to save themselves trouble, they have, very generally, let their Campagna estates, on long leases, to speculators, who, instead of cultivating them, or spending any money in reclaiming them, find it most profitable to leave them barren, and even to clear away what remains of habitation they may find, to make room for vast flocks of sheep, which roam over the hills and marshes, under the charge of a few half-savage herdsmen, brought from the miserable mountain villages of Umbria. The number of herdsmen required is so small that the actual density of population in the district under the very shadow of St. Peter's is substantially the same as that in the Pampas of Argentina. These wild men, the "sandalled ones," as the Romans call them, have no houses, living in huts made of cornstalks, or in holes dug in the ground. They have a superstitious dread of malaria, whose effects they know only too well, and, to ward off the "evil air," they kindle fires of rubbish near their huts, which, of course, serve only to attract swarms of mosquitoes, bearing infection with them. In the whole Campagna there are only eighteen official physicians, so that the public health receives practically no attention whatever; and the Italian Government, although it understands the condition of the district, has not felt itself strong enough to take any effective means for remedying it.

THE scheme, which is said to be due to the lamented King Humbert, of Italy, for supplying water to the dry regions of Apulia is to be carried out, the necessary legislation having been completed. The water is to be taken from springs high up in the Apennines, and is to be conducted through a main aqueduct, nearly two hundred miles long, eight miles of which is carried by a tunnel through the ridge of the Apennines to the edge of the Apulian plain. Here the aqueduct divides into many branches, which serve one hundred and ninety-four villages, containing seventeen hundred thousand inhabitants, situated in the provinces of Foggia, Bari and Lecce. The total length of the branches is forty-three hundred miles, and the cost of the undertaking is estimated at twenty-seven million dollars. The people of the territory to be supplied are among the poorest and most wretched in Italy, so that no attempt will be made to earn interest on the investment, by means of water-rates, fountains being simply established in each village for public use.

A FIRM in Germany, taking a hint, perhaps, from the people in the suburbs of Lyons, who whitewash even their tile roofs, has prepared a cheap white paint, apparently containing Portland cement, which is put with a brush directly over the tarred felt roofs so popular there. A roof of tarred felt, without the covering of gravel commonly used in this country, becomes intensely heated in summer, through the absorption of the rays of the sun, and heats the rooms under it; and the manufacturers of the new paint claim, probably with reason, that the rooms under a roof covered with it are much cooler in hot weather, while the paint, by protecting the tar in the felt beneath it from the sun, prevents the evaporation of the volatile constituents of the tar, and this prolongs the life of the roof. In New England, where the sun's rays have less power than they have farther south, and where the white gravel generally used over a tarred roof reflects much of the heat, roofs of this kind are popular and satisfactory; but in New York and Philadelphia they are considered to deteriorate rapidly, and it seems as if a good coat of cement whitewash might do much to protect them, and to extend the use of what is, under favorable circumstances, one of the best and cheapest of roofing-materials.

THE first stage of the competition for the Liverpool Cathedral has been completed by the selection of five, out of the one hundred and three competitors in the preliminary trial, for invitation to compete again. These five are Messrs. Austin & Paley, of Lancaster, and Messrs. C. A. Nicholson, George Gilbert Scott, Malcolm Stark and W. J. Tapper, of London. Of these, Messrs. Austin & Paley, George Gilbert Scott and Malcom Stark are well known to fame, even on this side of the Atlantic. Mr. Tapper is somewhat prominent in the profession in England; and Mr. Nicholson appears to be comparatively a new man. He must, however, be a man of great ability, for, besides the award of selection for the second competition which he wins by one of his designs, a second design, also submitted by him, receives honorable mention.

THE *Builder* gives an interesting account of the great dam across the Nile, at Assouan, now just completed. It will be remembered that, when the project of storing the flood-waters of the Nile was first discussed, a site was selected for a dam just above the First Cataract, and a little below the Island of Philæ, where the river passes between high, rocky banks. A dam could be built here, sixty feet high, giving ample storage of water for many years; but the ruins of the Philæ temples, which stood just above the dam, would be completely submerged; and, in deference to the universal outcry against destroying these monuments of antiquity, the plans were changed, so as to make the dam much lower. It is this last plan which has been carried out; and, although the Temple of Hathor and the Nilometer will be entirely under water during the three months of flood, the Temple of Isis will be covered only to the floor. Considering that the new dam will give much less than one-third the storage capacity of the one originally projected, so that the water must be used with great economy, it may be questioned whether the Egyptian peasants have much reason to applaud the scruples of the archæologists, especially as the soaking of the mud and silt on which the ruins of Philæ stand is likely to destroy them before many years; but it is too late to make any change now.

SOME of the circumstances attending the execution of this great work have a curious air. We are told that, for the sake of economy, no trial borings were made to test the ground on which a dam a mile and a half long was to rest, it being comfortably assumed that "sound rock would be found everywhere at a convenient level." Unfortunately, this assumption was not confirmed, and, after the contract was signed, an immense amount of extra foundation work had to be done, to carry the footings down to solid ledge through the "rotten granite," and masses of "micaceous schist, of a very friable nature," which existed in various places. Notwithstanding these troubles, the work seems to have been carried through with characteristic British persistency and thoroughness, and the engineers and contractors have good reason to be proud of what they have accomplished. A novelty in water-storage, which it was necessary to provide for, arose from the necessity of allowing the first waters of the Nile flood to escape through the dam. It is these waters which bring down the fine silt on which the fertility of the Nile valley depends; and to cut it off would be to ruin Egyptian agriculture. For this reason, an immense number of sluices are provided, near the base of the dam, which are opened when the first flood-waters appear, and kept open until the "red water" has been succeeded by that clearer product of the melting snow on the Mountains of the Moon. Then they are closed, and the clear water allowed to accumulate, to serve, later, for simple irrigation.

RELATIVE PERMANENCE OF STEEL AND MASONRY CONSTRUCTION.[1] — II.

W. HILDENBRAND, M. Am. Soc. C. E. — With reference to the old Roman viaducts and aqueducts mentioned in this discussion, which are frequently quoted as evidence of the longevity of stonework and its superiority over iron structures, the speaker wishes to draw attention to the fact that in other Roman structures may be found equal evidence of the durability of iron. Remnants of bridges over the Rhine, built by Julius Cæsar, have been dug up during the past fifty years, while the work of regulating the bed and current of the Rhine has been going on. In Cæsar's "*Commentarii de Bello Gallico*" one of these bridges is minutely described, corresponding in construction to what would now be called a timber trestle, consisting of heavy oak logs connected with iron bolts, clamps and spikes. Quite a number of these logs were found under the bed of the river, nearly 2,000 years after they had served for carrying the Roman legions over the Rhine in their attempt to subjugate a free nation, and the timbers, as well as all iron bolts and spikes, were in a perfect state of preservation.

This fact corroborates Mr. O'Rourke's assertion that iron submerged in pure water will probably never corrode.

Of course, every object in this world perishes, or, rather, disintegrates and changes into some other form; but, if building materials can be preserved for several thousand years, it may be said that, for all practical purposes, they last forever.

The question whether metal will in the future be considered as permanent and durable a building material as stone cannot be solved at the present time, and it is not likely that any who are here will live to see it solved. The answer to the question cannot be found by theorizing, but depends entirely on experience, which should extend over centuries.

At present we have, so to say, no experience at all about the durability of iron or steel structures. It is barely sixty years ago that the first iron bridges were built, and it is doubtful whether a single one of that age is in existence to-day. Nearly all the early iron bridges have been removed and replaced by modern structures, not on account of having been decayed or weakened, but because they had outlived their usefulness, and stronger ones were required to accommodate the increased and heavier travel of modern times. Our experience as to the durability of iron and steel structures, therefore, is very limited, and only of recent date.

If a stone building and a steel building were erected side by side, and both structures were left to themselves, without any attempt to protect them against the effects of the atmosphere, there is no doubt that the stone building would stand very much longer than the steel building. In New York City there is an example in the New York and Brooklyn Bridge. The massive stone towers, which are now more than twenty-five years old, have no protection against the weather and have never been repaired. They are to-day as they were left by the hand of the mason twenty-five years ago, and according to a recent thorough inspection, they are just as good and perfect as they were on the day they were finished. On the other hand, the steel and wire work requires constant attention; there is hardly a time when no men are seen suspended in the meshes of the wirework repairing something or putting on a coat of protective paint.

The speaker has had the opportunity of examining suspension-bridges erected more than forty years ago, and while he found the cables, as a whole, in perfect condition, he also discovered one or two places where, through the accumulation of water or through imperfections in the protective paint, the wires were considerably corroded and needed repairs. All of this shows that metal structures require attentive watching and constant renewal of paint or other protective coverings, and that any oversight or inattention is followed by grave consequences.

With our present knowledge, therefore, we may sum up by saying that unprotected masonry, as well as unprotected ironwork, is perishable, but that the former will last much longer than the latter. However, if iron or steel be well protected, it is known that it will not decay in thousands of years, and will be as durable, if not more durable, than any stonework. Will the means for an efficient and permanent protection of steel ever be discovered, or will a new metal be found which has the same strength as steel and which naturally is not subject to oxidation?

H. S. HAYNES, M. Am. Soc. C. E. — Mr. Hildenbrand has referred to iron bolts in bridges built by Cæsar across the Rhine. In the Colosseum, built about A. D. 80, the courses of heavy travertine masonry, laid with knife-edge joints, without mortar, were connected by iron cramps fairly well protected from the weather. Many of these were cut out in the Middle Ages, but those which remain appear to be in good condition. The vault of the Pantheon, 140 feet in diameter, is of concrete supposed to be strengthened with iron rods. This vault, built about A. D. 125, is, to all appearances, in excellent condition. From these instances, it would seem that iron, used structurally in connection with stone or concrete masonry, may remain efficient for nearly 2,000 years.

Iron is not readily oxidizable in pure water, for the oxygen therein chemically combined is only separable at an excessively high temperature. It is the atmospheric oxygen ordinarily present in water that is the oxidizing agent. Water absorbs carbonic-acid gas to an extent equal to its volume, and the water thus acidulated acts powerfully upon iron or steel. It follows that in large cities where the atmosphere is heavily charged with the products of combustion, the falling rain would be correspondingly charged with carbonic-acid gas, and, therefore, that the effect of oxidization upon steel construction should be proportionately greater from exposure under such conditions.

A. L. JOHNSON, M. Am. Soc. C. E. — In reference to a statement concerning the corrosion of the steelwork in the large buildings in Chicago, C. T. Purdy, M. Am. Soc. C. E., was one of the members of a Commission to examine and report on the condition of those buildings. The speaker having talked with Mr. Purdy recently concerning this matter, it may be appropriate to give some of the results as described by Mr. Purdy. His report has undoubtedly been printed ere this, and probably, therefore, there will be no objection to the promulgation of the information at this time. The Commission examined quite a number of the buildings in Chicago and found numerous cases of corrosion in the columns; but it was not developed that the corrosion was confined to the outside columns, or even that it was greater in them than in the interior columns. The beams in the foundations, Mr. Purdy said, were found to be in uniformly good condition. The Commission's recommendation would be that in future all the steelwork for these buildings should be entirely surrounded by a Portland-cement or lime mortar, this covering being filled-in solid behind the fireproofing.

In St. Louis a very well constructed building, erected about twenty years ago, is now being dismantled. The construction consisted of solid external walls, cast-iron columns throughout the interior, and steel beams painted with red oxide-of-lead paint. The building was eight stories high, and of fireproof construction, the floor-arches being mainly of brick, though there were also some concrete arches. The steel throughout is in a thoroughly well-preserved condition, it having been in all cases entirely embedded in Portland-cement mortar or concrete covering. The paint also has been thoroughly preserved, and in the speaker's estimation an embedment in Portland-cement mortar is the only means of preserving that preservative.

Professor Spencer Newberry, Manager of the Sandusky Portland-cement Company, recently gave a lecture[2] in Chicago, which the speaker regards as one of the most valuable articles, with regard to steel-concrete construction, that has appeared in print for some time, covering, as it does, all sides of the question, and some sides in an entirely new manner, such, for example, as the theoretical considerations involved in the preservation of iron by Portland-cement covering. In this article he shows that the cement, theoretically, is not simply a neutral or non-injurious agent, but is actively engaged in preventing the formation of rust.

The speaker's company has samples of steel embedded in cinder-concrete, in the form of broken pieces of a test span, made in the fall of 1898, and tested in February, 1899, these pieces having lain on the ground uncovered, subject to the action of the elements, for more than three years. On numerous occasions these pieces have been broken open for the purpose of observing the condition of the metal, the most recent case having been before the Engineers' Club of St. Louis, last January, in connection with a talk given by the speaker; and in all cases, without any exception, the metal has been found to be as bright and clean as the day it came from the rolling-mill. The quality of the cinders in this sample was considered very poor, containing a good deal of dirt, and the fine material was screened out. This the speaker regards as desirable, though not absolutely necessary, where cinder-concrete is used, inasmuch as, if it is not done, a slight film of rust will be formed on the metal. This film, however, never increases in thickness, but, as it costs little to avoid it, the best practice would call for the screening of the cinders. In the speaker's opinion, the reason for this difference in action is due to the fact that the fine stuff contains finely divided particles of sulphur, which are readily dissolved by water, slightly acidulating the same, and, until the concrete dries out thoroughly, a slight corrosive action is taking place. This is soon neutralized by the influence of the Portland-cement, but not before a film of rust, not in itself materially injurious, is formed.

Mr. Darrach has expressed himself as of the opinion that at the present time we are not able to calculate the strength of steel-concrete beams with any degree of accuracy. The speaker, of course, will have to take exception to that statement, he having on numerous occasions endeavored to show how this could be done, and, being of the opinion that the data with regard to the materials used being known, he could arrive at the maximum carrying capacity within about 15 per cent, which is certainly close enough for all practical purposes, in view of the factor of safety used. Of course, the strength and the modulus of elasticity of the concrete and steel must be known, and, as to the former material, these functions are seldom accurately known, chiefly because no special tests are made to determine this for the materials available for that particular work. Their influence on the character of the design is enormous, and, on work of any considerable size or importance, these values should be obtained before the designs are prepared.

As to the relative lasting qualities of the different kinds of engineering structures, the speaker is of the opinion that only a few forms

[1] An Informal Discussion at the Annual Convention, May 21, 1902, of the American Society of Civil Engineers and printed in the Society's *Proceedings* for August, 1902. Continued from No. 1398, page 13.

[2] Before the Annual Meeting of the Associated Expanded Metal Companies, and reprinted recently in *Engineering News*.

of stone masonry can compare in length of life with a concrete construction reënforced with steel properly distributed through the cross-section. Strange as it may seem to those not conversant with the facts, the maintenance-charges for stone masonry, on many railroads, exceed these charges for steel structures in proportion to the relative quantities of each. On railway work it is usually a condition of taking what you can get, rather than what you would like to have. Many forms of sandstone are worthless. Limestone is dissolved in the course of time by atmospheric influences, and there are really only a few kinds of stone that can be considered as everlasting, and these are usually so expensive as to prohibit their use. A very good example of the dissolution of limestone masonry is afforded at the Cabin John Bridge. Underneath the arch may be noticed stalactites forming along the line of the mortar joints between the granite arch-stones, from the spring-line so ne distance up toward the crown. The back-filling of the arch consists of a considerable depth of limestone-rubble masonry. A considerable quantity of water finds its way down through the haunches of the arch and then through the mortar joints of the arch-ring, and the stalactites indicate that the air and water are dissolving this limestone backing. This same action exists, to a greater or less degree, in all limestone structures.

In a large city in Indiana the speaker recently examined some limestone bridge-masonry which had been in place for about forty years, and much of it could now be scraped up with a fire-shovel.

In the speaker's opinion, plain concrete construction would not be everlasting, on account of the cracks which are almost certain to develop in such structures, these cracks filling with water and freezing in the winter, and gradually getting worse and spawling off as the years go by.

In steel-concrete construction, if the metal is properly distributed and proportioned to the cross-section, these cracks can be absolutely prevented. The speaker's company has built walls 300 feet long, with steel reënforcement, in which no expansion-joints were provided, and in which not a sign of a crack is to be seen; and would take a contract to build such a wall a mile long, under this guaranty.

To accomplish this result, however, it is necessary to have a subdivision of the metal reënforcement into small areas thoroughly disseminated through the section, just as in successful arch-construction it is necessary to have the metal thoroughly disseminated in small areas through the upper and lower portions of the sections. Heavy concentrations of metal at points 2 or 3 feet apart will not give the peculiar stretching quality to the concrete obtained by the other method, and which is essential to success.

When properly built, this steel-concrete construction will not crack; will not be disintegrated by frost; will not be dissolved by the elements; and, in the speaker's opinion, is the only kind of engineering structure that can be considered permanent, with the exception of one or two kinds of rock masonry, the cost of which in most cases would be prohibitive.

F. Lynwood Garrison, Assoc. M. Am. Soc. C. E. — Since there seems to be some confusion or misunderstanding regarding the corrosive action of atmospheric and other influences upon iron, it might be advisable, in this discussion, to state briefly a few of the most important characteristics of metallic iron that are pertinent to the subject, although, in so doing, the risk of repeating some well-known facts must be incurred.

1. To begin with, iron is one of the metals most easily oxidized and affected by moisture, consequently it never occurs in the metallic state.[1]

2. Iron does not undergo any alteration in pure dry air at ordinary temperatures.

3. In moist air iron becomes coated with ferric oxyhydrate having approximately the composition $Fe_4O_2(OH_6)$. The rust varies in composition with the conditions under which corrosion takes place.

4. According to Percy, iron does not rust unless there is an actual deposition of liquid water upon the surface of the metal.[2]

5. The presence of certain gases and vapors, even in minute proportions, such as sulphuretted hydrogen (H_2S), hydrogen, chlorine, and acetic acid, accelerates rusting in moist air, though no liquid water may come in contact with the metallic surface. Carbon dioxide (CO_2) and ammonia gas are said to act less energetically in this respect.[3]

6. Iron rust often contains minute quantities of ammonia, due, it is supposed, to the decomposition of the water by the action of the oxide on the metallic iron, the oxygen combining with the iron, and part of the hydrogen uniting in the nascent state with the nitrogen of the air.

7. Pure water deprived of air appears to be absolutely inert, as far as corrosive action is concerned, on contact with iron, even at 100 degrees Cent.[4]

8. Rust formed far beneath the water consists of black hydrated magnetic oxide.

9. The formation of rust takes place in the beginning but slowly; after a thin coating has once been formed, the corrosive process goes on more rapidly.

10. Aqueous solutions of potash, soda and ammonia preserve iron from rusting, provided they are not too dilute.

11. Water containing not more than one-fifth its volume of lime-water is said to preserve iron from rusting.[5]

12. The contact of iron with more electro-positive substances, such as zinc, retards corrosion; whereas contact with more electro-negative substances, such as tin, lead and copper, accelerates the rusting.

13. Magnetic and similar oxides of iron, which constitute the basis of iron scale, protect the iron which they coat, but hasten the corrosion of rusted iron, whether such be the adjacent portions of the same piece or in separate pieces which are galvanically connected. This protective action is shown by the comparatively slow rusting of Russian sheet-iron, of "blued" iron, and of castings that retain their original skin.

14. While contact with zinc and highly zinciferous brasses retards rusting, contact with copper, or brasses rich with copper, hastens it.

15. According to Martell, the purer qualities of mild steel when used in ship-hulls are more likely to be corroded than impure iron. A steel ship requires more care than an iron one. Nickel steel is not so likely to be corroded in salt-water as the ordinary and purer grades of steel.[6]

This array of more or less well-known facts might be indefinitely elaborated; however, it covers the subject completely in a general way. It seems to be a perfectly sound conclusion that, other things being equal, where likelihood of corrosion is effectually prevented, iron (steel) makes as permanent and durable a building material as masonry. Better, in fact, for, whereas the latter will certainly, in time, disintegrate, the former cannot. Unusual conditions may certainly exist in which the molecular structure of the metal may change; such, however, must be regarded as abnormal and exceptional.

A statement has been previously made in this discussion to the effect that, inasmuch as iron properly covered with fireproof material or concrete will not corrode, uncovered iron in the interior of buildings will be immune from corrosion because it is then covered from the weather on all sides. Were walls and roofs absolutely water or moisture proof, in fact, if the buildings were hermetically sealed, top, sides and base, then, and then only, would the interior metal be free from corrosive influences. As a matter of fact, in most cases, the danger from corrosive deterioration are much exaggerated; the greatest objection to steel buildings is their instability in fires. Mild steel, at a white heat, is about as stiff as cheese, whereas masonry is not affected in the same way at high temperature, and resists collapse to a far greater degree.

The speaker's belief is that, in practice, a thick covering of cement-concrete is the only material that absolutely protects iron from corrosion. Such a compound structure unites the advantages of both component materials, and greatly surpasses in strength and durability an edifice made of either alone.

All are familiar with the remarkable strength and endurance of "wire-glass," the glass sheet being cast and rolled so that the wire net is completely covered with the glass, imparting to the natural fragility of the latter a certain amount of elasticity and abnormal strength; the glass, in turn, absolutely protecting the wire from corrosion. So long as the wire is covered, such a composite sheet will hold together, unless broken by a force greater than the tensile strength of the wire.

Not being a structural engineer, the speaker may be unfamiliar with certain objections to composite concrete and metal structures; in his ignorance, however, he cannot but think that such compound constructions will be the true and logical line of development in the future.

[1] Exceptions must be made where the iron is of undoubted meteoric or non-terrestrial origin. In such instances, it is usually alloyed with a large proportion of nickel.

THE TOWER OF ST. MARK.

THERE is still to be seen on the Piazza of St. Mark a lamentable mass of ruins containing all that is left of the bell-tower of the Venetian Republic; but busy hands are rummaging amongst this mass of rubbish, this dusty pile, for the sake of withdrawing from it any uninjured pieces of the Campanile, and the great court-yard of the Ducal Palace is transformed into an ossuary where are already accumulated the scattered members of the colossus. These members, bas-reliefs, bronzes, statues and decorations are here carefully grouped together, awaiting resurrection. One might call them an image of a monument painfully sketched-out as in a dream, a maladroit evocation. One might imagine that these works of art gathered together here are fatigued through having been throned on high during long ages over the grand public place of Venice, and are disturbed at the idea that they must again take their place in the eye of the sun.

One of the bronze statues from the Loggetta, Minerva, has lost her buckler; her sword is broken, her casque is cleft by a terrible blow. Apollo, headless and dismembered, lies on the ground; Mercury is disfigured, and has lost his nimble hands. There are also a certain number of statues which the most painstaking effort will hardly succeed in curing of the wounds caused by their fall, and fitting them for a place on the new pinnacle, which is going to be erected for them.

You doubtless know that the engineer, Signor Giacomo Boni, has been summoned to Venice, and ordered to prepare for the rebuilding of the historic tower. From the Roman Forum, where he

was directing the new excavations with extreme ability — where he has already made some astonishing discoveries, the young engineer has gone to care for the Venetian Forum — that group of monuments of a different epoch, to be sure, but one which equally recalls several fair pages of history, and at the same time is a precious necklace of artistic treasures. A link has given way under the weight of time; the Campanile has crumbled, and Signor Boni has begun his work by carefully picking over the ruins.

It is only in the early days of the month of October that an ending will be made of cleaning up the Piazza. The thing which makes the work difficult is the fact that the tower, which was unwilling to throw itself upon St. Mark's, or upon the Ducal Palace, has buried under its ruins a portion of the arcade of the Royal Palace. It might have dragged them down in its own fall, if it had had less thought for the surrounding monuments. It will be necessary, therefore, before disinterring this arcade, to shore it up in some fashion, after the Piazza is cleared up; and before laying the foundations of the new tower, it will be necessary to make excavations, so that a study of the structure of the sedimentary deposit may be made, and any defects in the old foundations laid bare. These excavations will extend through a zone of about 6 metres beyond the old foundations of the monument, and will go 4 metres below them. The second portion of the work, having to be carried out with extreme care, cannot be finished before next spring; then the new foundations will be laid, with an area of from 200 to 400 square metres, on ground consolidated by piles which are to be driven by the quiet and non-disturbing action of hydraulic pressure.

It is natural that investigations into the stability of the Venetian soil, the sinking of the ground-level, its movement, its former undulations, and those which are still to be feared, should have to be carried out with extreme slowness. Fortunately, they have discovered an aid of extreme importance — a bench-mark; on the third gradin, at the left of the entrance to the Campanile, there has been discovered an ancient mark indicating the sea-level. Thanks to this mark it will be possible to know whether there has been any sinking of the foundations of the tower, and as well, whether other parts of Venice have sunk also. As it is a question of level, in relation to the primitive level of terra firma, they now have a new factor for studying the problem of the general subsidence of the islands in the Lagoon, a problem of capital importance for Venice, whenever the stability of its monuments are considered.

This subsidence of the ground-level is a fact abundantly proved. It is now only necessary to determine how important a factor it is. The level of the Roman paving in Venice lies 2 metres below the present level, while the level of the mediæval pavement lies only 1.70 metres below, and this gives a coëfficient of geological subsidence of 9 centimetres for each hundred years. The phenomenon is one of great importance, and it is time that the Venetians took proper cognizance of it. As to its causes: it is thought that it had been found in the settling of the layer of clay into which the piles have been driven. Moreover, the phenomenon is continuous and periodic. It is enough to recall that the ancient monuments were built flush with the water, that it is only from the year 500 that buildings were placed on gradins, and the Piazza of St. Mark itself offers a curious example of this. The Campanile, which is the most ancient monument on it, was, before its fall, lower than it was intended to be by its builders, because of the fact that the pavement of the Piazza had been raised. In fact, under the modern pavement is found an earlier one; then, lower still, are found relics of the *opus spicatum* of the Middle Ages, such as we see it in the paintings of Gentile Bellini, and, finally, still farther down, we come to vestiges of Roman occupation and the level of beaten earth, upon which walked primitive man.

Signor Boni excels in archæological investigations. He has created a special method, of which I shall shortly probably take occasion to write to you, which has enabled him to reconstruct, in great part, the primitive history of the Roman Forum, by a system of vertical research and horizontal examination of successive layers of ground, of pavements, of substructures, more or less ancient, of historic stories [*étages*], in a word, and as the Piazza of St. Mark is really the Venitian Forum of Roman times, the excavations which he is going to carry out will probably give rise to discoveries of great historic importance.

Because of the subsidence an interesting problem presents itself. Ought the Tower of St. Mark, which it is desired to have rebuilt on the same spot — with the same architectural proportions — a perfect copy in fact, to be built to the same height from the present level of the Piazza, or still higher? for the Campanile has buried itself to the amount of 70 centimetres, so that it was by so much lower than when first erected. Of the five gradins which form its base, two and one-half had become buried beneath the level of the Piazza, and as it is now a question of historical restoration, it ought to be right to take account of the origin of the Campanile, and rebuild it to its original height. Objection has been made to Signor Boni that this heightening of the Campanile might disarrange the harmony of the lines of the Piazza, through the equivalent lowering of their lines, but it is only necessary to remember that 70 centimetres is no great portion of a tower nearly 100 metres high.

One thing Signor Boni absolutely refuses to do, and that is to rebuild the Campanile in any other spot. To do this would be to disarrange the harmony of the entire group of buildings on the Piazza, since the Campanile being the most ancient structure there, it is entirely natural that the architects of the other monuments must have taken it for their point of departure. "Any displacement," says Signor Boni, "would disturb the symmetry of the Piazza; and in making use of the word 'symmetry' I give it its Greek meaning, and not that which is directly attributed to it. Symmetry does not mean equality; the word rather signifies a harmony of the *ensemble* of elements that are not discordant, but merely unequal. The Acropolis for example, is composed of members that do not repeat one another, but that does not prevent its having perfect symmetry."

The new Campanile will differ from the old one only in certain details of construction, in its foundation, in its elevation, in the employment of resources of modern construction. Signor Boni is absolutely determined that the material employed shall guarantee a perfect stability. He will, therefore, watch over its choice. The old monument was composed, in great part, of old Roman material. There have been found amongst the ruins splendid specimens of brick of the first and second centuries, marked with the stamps of Nero, of Claudius, and of Antoninus Pius. There have also been found a score of bricks with unknown stamps which have revealed many things — such as the existence of Roman *figulinæ* (brick-yards) in the cities of the vanguard, which, on the slope of the Alps, the Latins built against the invasion of the barbarians; and also of the active life of the garrison of these cities, and several details of their domestic life. Several of these bricks still bear the imprint of the footmarks of animals who trampled on them while the clay was still green, and there are imprinted stamps of domestic animals such as goats, lambs and pigeons. Upon these bricks have been found traces of ancient Roman mortar, which, as is well known, was very strong; while the Venetians of the Middle Ages used a mortar composed of Istrian lime and a calcareous débris — a mortar, moreover, which did not set properly, as it absolutely lacked hydraulicity. In the reconstruction which is being planned with a view, particularly, to secure the greatest resistance to compression, it is almost certain that there will be found beds of clay which will yield bricks identical to those of Aquillia, which were indestructible. As to the mortar, it will be made from a mixture of Istrian lime and the famous pozzolana, which even resists dynamite. The foundations whose resistance is the chief consideration, will be reënforced, as I have said above, so that their powers of resistance will be doubled, and, finally, the soil will be consolidated by means of piles of huge dimensions.

As to the exact and integral reconstruction of the monument, it appears that Signor Boni has at his command all the necessary elements, the most exact drawings, from the piling up to the angel which used to crown the edifice. The reproduction, therefore, should be perfect. It will only be necessary to introduce certain modifications in the arrangement of the interior staircases, the hanging of the bells, and so on. The sole architectural modification will be the elevating of the whole by the 70 centimetres now buried beneath the pavement of the Piazza, and this will, at the same time, preserve historic fidelity and answer a technical purpose, because a granite socle can only consolidate the structure and protect its base from the saline emanations rising from the soil.

The Loggetta of Sansovino will also show itself once more. This graceful little structure had the misfortune to be backed against, or, as it were, hung against the Campanile. It will not be rebuilt in the same way. The Loggetta will be placed on the foundations of the Campanile — upon the same block — so that there will no longer be any cracks or movements to be feared. A quantity of fragments of statues from the Loggetta have been saved. Its historical restoration will therefore be easy. It is intended to restore it to its former function, that is to say, to serve as the entrance to the Campanile.

"In five years," Signor Boni says, "we shall hear again the 'Marangona'" — this is the name of the largest bell in the Campanile — and doubtless he will be able to keep his word.

As you see from these remarks, his plans have been very carefully studied, and we can count on his following out the execution of the work with the calm steadfastness and conscientious ability which distinguish him; but that which shows that Signor Boni is in true sympathy with his work is that he is in no way obsessed by the hysteria of the writers and artists who saw in the downfall of the Campanile di San Marco only a pretext for making a graceful flourish, and announcing to the whole world that their sensitive souls had been rent and wrung by the disaster, and that they had shed bitter tears over the ruins of the monument. A good deal might be said upon this hypocritical ranting, which has been only too favorably received by the newspapers, and at the inquests which were held over the fall of the tower. We will be content to present to the hearts of these too soulful artists the masculine figure of Signor Boni, who, without crocodile tears, or the aid of the hackney muse, is going to rebuild the Campanile, and who really is about the only man in Italy capable of accomplishing the task.

HONORÉ MEREU.

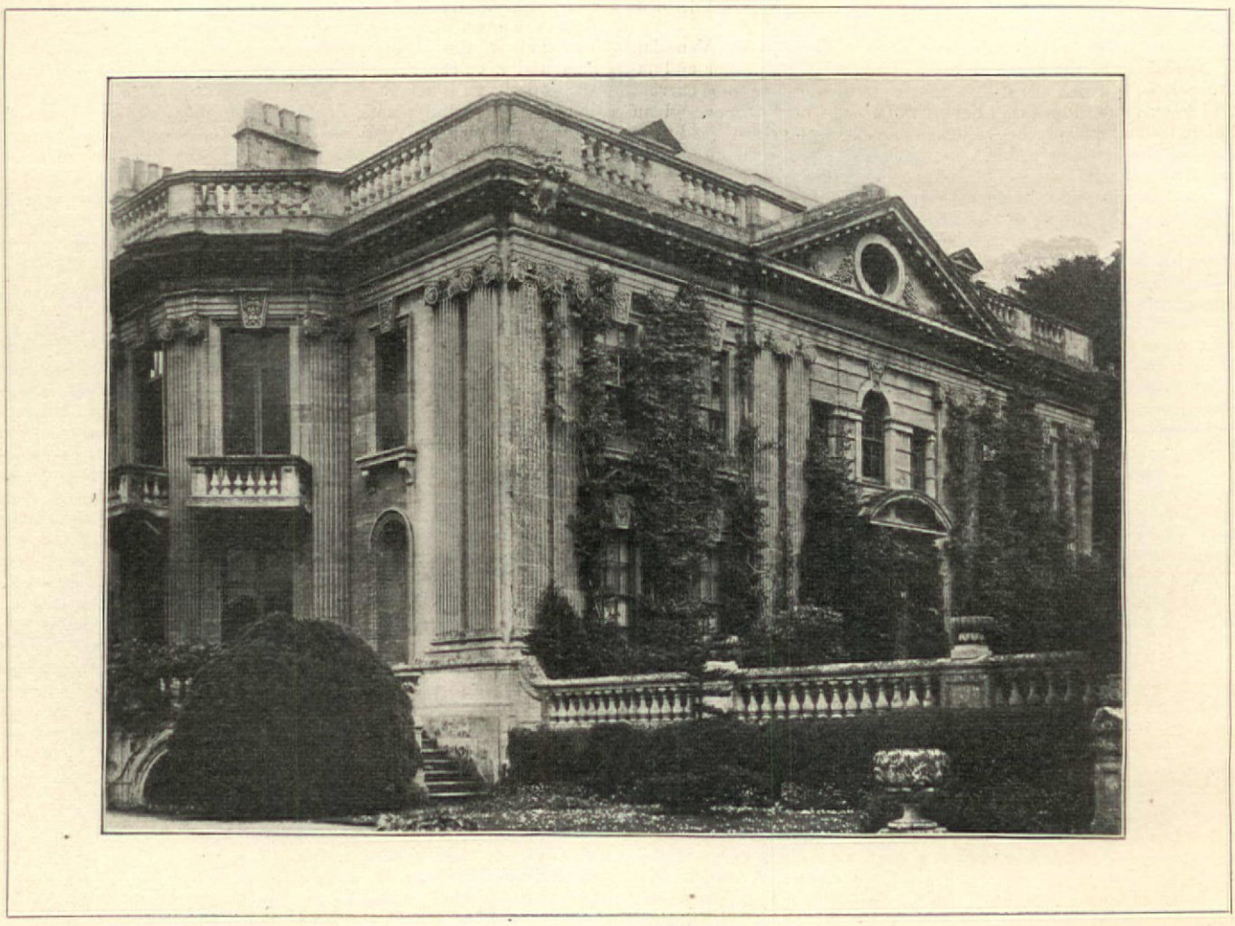
BOOKS AND PAPERS

THE first part of a very valuable book[1] has just appeared, "*The Eighteenth Century Architecture of Bath*" (England), by Mowbray A. Green, A. R. I. B. A. It is illustrated profusely by measured drawings, photographs, sketches and reproductions of old

[1] Published by G. Gregory, Argyle St., Bath, 1*s.* 6*d.*, in paper covers; 4 parts, and limited to 500 copies, numbered.

maps, and is a work which every architect interested in eighteenth-century domestic architecture will be glad to possess. Part I only takes us down to the first quarter of the eighteenth century when the elder Wood began his work of renovating the old city. Most of the houses were then a sort of transition from gabled Tudor frontages and mullioned windows to the Palladian style of the latter half of the century; and it is interesting to follow Mr. Green's illustrations showing this gradual adoption of Classic details. First of all, apparently, windows were altered, as we see large sash-windows take the place of casement-windows in the pointed gables; and then the gables disappear and we have broken pediments over the doors and windows, cornices and Classic doorways. Bath should be interesting to Americans, as its architecture must have been in some measure the cousin-german of the Old Colonial work. Looking through Mr. Green's book one sees details with which those cognizant of the Old Colonial architecture of the States are familiar. The luck of rebuilding a city which fell to the lot of the two Woods has rarely been experienced except in later times, under the last Imperial *régime* in France, when Baron Hausmann ruled lines across the map of Paris and swept away all buildings which came in the way of the new streets. Money was no object, as it was other people's! And apparently the elder Wood acted much in the same way. Landowners in Bath arranged for demolishing old buildings and putting up new ones, possibly with much too free a hand, for nothing or next to nothing remains in Bath of an earlier period except the Abbey church. And yet how benighted was the building-trade in those days. "In Wood's '*Description of Bath*' he makes the following cogent remarks on the working of Bath stone: 'My speaking of this House leads me to explain the Defects in the Management of the Mason's trade at *Bath*. Our Free Stone is beyond dispute a most excellent Building Material, as being Durable, Beautiful and Cheap: It has been generally worked in the Quarries upon the Hills round about the City by Men who stile themselves Free Masons, *i. e.* Masons, whose Province it is to work Free Stone, and from thence carried, ready wrought, to the several Places where it was to be used in Building; by which Means the sharp Edges and Corners of the Stones are generally broke. In this Condition the Free Stone work is usually set up by other Men, who call themselves Rough Masons, *i. e.* Masons whose Province it is to work the Refuse of the Free Stone or the common Wall Stones: and thus by dividing the Mason's Trade into two Branches, the Works in *Bath* lose that Neatness in the Joints between the Stones, and that Sharpness in the Edges of the Mouldings, which they ought to have: and which People accustomed to good Work in other Places, first look for here.' There is a great deal," continues Mr. Green, "to be said in favor of Wood's view of the matter, but of course, in his day it was impossible on account of the rough means of transit, to exercise such care in the use of the stone as at the present time. In addition to this, he had been accustomed to work executed in hard Yorkshire stone, which would preserve the sharpness to a much greater degree."

The book is unfortunately, of necessity, printed upon somewhat glazed paper, but as the four parts will consist of only about 200 pages, it will not be over weighty in spite of its numerous illustrations. It is the only work treating exclusively of the domestic architecture of Bath in detail and apart from the history of the city. All other works are more or less historical "guides."



Widcombe House, Bath, Eng.

AUSTRALIAN SOFT WOODS.

THE heavy timbers in which Australia is so rich have become famous for their exceptional hardness and durability, but comparatively little is known outside the Commonwealth of the numerous soft woods admirably adapted for the manufacture of furniture and for other industrial purposes. Such timbers are abundant in New South Wales, and are found principally in the immense brush forests of the coastal districts. Several of these timbers have a wood grained and marked most beautifully, and capable of receiving the highest polish, while others are fragrantly perfumed. Amongst the chief varieties of woods of this class may be mentioned the red-cedar, the beautiful wood of which is admirably adapted for the finer kinds of cabinet-makers' work. Some of the cedar-trees grow to immense size, as much as 2,500 cubic feet of valuable timber having been obtained from one tree. In addition to the cedar may be mentioned tulip-wood, yellow-wood, white-maple, myall, marble-wood, mock-orange, and many others. Besides their use for cabinet-making, many of the brush timbers are of great utility for the rougher kinds of carpentry, while some, both hard and soft woods, are admirably adapted for coach-builders' and coopers' work. The chief description of pine growing in New South Wales is the Moreton Bay white-pine, found in the coast districts as far south as the Bellinger. It is soft, light, and easily wrought, and suitable for all the interior woodwork of houses, as well as for cabinet-making. The red or black pine is extensively distributed over the Liverpool Plains, and in the Lachlan and Darling River districts, as well as around Berrima. It is beautifully marked in the grain, takes a fine polish, and has an agreeable fragrance. There are numerous other varieties of pine, but these resemble in their main features the trees already described. Australian deal is an excellent timber, and is obtained in very large scantling, the tree frequently reaching 120 feet in height. It is soft, close-grained, easily wrought, and remarkably free from knots. Its use, therefore, is extensive for cabinet-makers' work and

house-fittings. The New South Wales Government Statistician mentions several of the more useful of the soft and fancy woods of the State. They include the beech, which attains a height of 100 to 150 feet, with a diameter of 3 to 5 feet, giving a strong white, close-grained, and durable wood, easily worked, and greatly valued for decks of vessels, flooring, turnery, and furniture-making; the black bean, growing to a height of 120 to 130 feet, with a diameter of from 4 to 5 feet, with a handsome, close-grained, dark-colored, durable wood; the black-oak, used for bullock-yokes, tool-handles, shingles, etc.; and the black-wood, resembling walnut, and highly valued for making furniture. Another valuable timber is the rose-wood. It is strong-grained and durable, with a color resembling Spanish mahogany. Among other woods may be mentioned the silky-oak, which attains a height of 70 to 80 feet. The color is a light gray, beautifully crossed with silvery waves, and when polished the surface has a delicate lustre. Bedroom suites made from this wood possess a dainty appearance. Satin-wood is another useful timber, yellow in color. It is soft and silky to the touch, close-grained, and easily wrought. This wood is also suitable for cabinet-making, and is considered to be superior to the satin-wood used in the European and American furniture trade. When the system of forest conservation becomes more general in the State, the supplies of many of the timbers mentioned will become practically inexhaustible, and are certain to be in large demand for export purposes.

THE ROMAN CATHOLIC CATHEDRAL, WESTMINSTER, LONDON, ENG. MESSRS. JOS. F. BENTLEY & SONS, ARCHITECTS.

WE republish this week, from the *British Architect*, a plate taken from a large drawing, prepared under the direction of the late Mr. Bentley, which doubtless illustrates the exterior of the Cathedral from its most favorable aspect, and which is not liable to the defects that inevitably arise in photographic records. The drawing was prepared from the architect's scale-plans of the building, and corrected in detail from the work itself. It shows, moreover, the tympanum of the great entrance filled with mosaic after the cartoon prepared for the work.

The foundation-stone of the great church was laid on June 29, 1895, by Cardinal Vaughan. The total expenditure for work and material up to July 25, 1902, has been £162,871, but no cost of the Archbishop's home has been borne by the Cathedral Building Fund.

The Cathedral stands on a site of some 4 acres in Ashley Gardens, close to Victoria Station. It is entered by a fine porch, and the plan consists of a porch, a narthex, or vestibule, extending across the whole width of the Cathedral; a nave and two aisles, with eight side-chapels and transepts; a sanctuary, 4½ feet above the level of the nave, with the Blessed Sacrament and the Lady Chapel at the sides; beyond the sanctuary a raised choir, 13 feet above the nave, for the chanting of the Divine Office, with a crypt beneath it; a spacious gallery over the aisles and at the west end; and, behind the Blessed Sacrament Chapel, two vast sacristies and other rooms connected with them. The external dimensions are: Extreme length, 360 feet; width, 156 feet; height of nave, 117 feet; height of façade (not including the turrets), 101 feet; height of campanile, 273 feet; and to the top of the cross, 283 feet. Internally, the dimensions are: Length from the main entrance to the sanctuary, 232 feet; depth of the sanctuary, 62 feet; and of the raised choir beyond it, 48 feet — making the total internal length 342 feet; width of nave, 60 feet; width across nave and aisles, 98 feet; across nave and aisles and side-chapels, 148 feet; height of the main arches of the nave, 90 feet; and of the three domes of the nave, 112 feet. The chief materials are very hard brick and stone, set in cement-mortar. The foundations, of most solid construction, rest everywhere upon a bed of concrete which varies from 4 to 10 feet or more in depth. The external walls, to the height of 8 feet from the ground, are of granite; and the structure above is of red bricks, with a very large amount of decorative work in Portland-stone.

Internally the appearance of the Cathedral is exceedingly impressive, with the full view of its 342 feet of length; its vast nave, much wider and higher than any nave in England; the twelve lower arches on each side of the nave, supporting the stately gallery; above each two of these arches a lofty arch of 73 feet in height; above each two of the latter a still loftier arch of 90 feet; and, rising above the highest arches, the three domes of the nave. Besides the massive piers, there are (in the nave, aisles and transepts) twenty-eight columns of marble, with a marble front to the gallery; and the lower walls, and the piers to the height of about 38 feet are being covered with marble. The whole upper part of the piers and walls, the vaults and the concrete domes will be decorated with mosaicwork illustrating the history of the Roman Catholic Church.

For the flooring Mr. Bentley had prepared a design in marble, with squares of cipollino, in which were set fishes of a slightly red-tinted marble swimming in the rippled waves of the sea. An allusion to the idea of the church being a ship bearing her burden safely over the sea of life. This floor would have cost some £15,000, and, moreover, would have been of doubtful quality for a vast crowd of kneeling worshippers, who are liable to effect of chill even when such a floor is covered with matting. In Vienna the marble floor of the Cathedral is overlaid with boards in the winter, in Spain the floors are covered with mats, and in St. Peter's, in Rome, a plank is put down, on which the deacons stand to sing the Passion in Holy Week. It has been decided for the present to use a wood-block flooring, which is warm, noiseless and comfortable. The narthex, however, will contain Mr. Bentley's marble flooring, and the piers and columns will be bound together by a marble framing; so that the wood-block will appear as a canvas enclosed in its frame.

The acoustic properties of the Cathedral have turned out to be unexpectedly excellent. A speaker standing in the apse has been heard distinctly at the entrance-door of the Cathedral — the nave being empty. What will be the effect upon sound of a large audience filling the nave is one of the results looked forward to from the performance of music that will be given on the 11th of June. The science of acoustics appears still to be in an extremely backward condition, for no architect seems to know what his church will do with the sounds of the human voice produced in it. Mr. Bentley *hoped* that the preacher would be heard distinctly; but not even he could be sure until the experiment had been made.

The construction of the domes should be noted. No iron whatever is used in their construction. They are built of concrete of 4 parts broken brick to one of Portland-cement mixed with the least possible quantity of water. The concrete was prepared on a stage round each dome and thrown fresh on to the boarded centre, sanded to prevent its adhesion, in ranges varying from 3 to 5 feet deep, and screened on the upper surface to a graduated thickness so as to ensure an absolute uniformity in longitudinal and latitudinal section. No cement was used until it had been 13 weeks on the site and periodically turned over.

NOTES AND CLIPPINGS

THE LION OF LUCERNE. — A great deal of anxiety is felt in the country through the discovery that one of Switzerland's chief historical monuments — the Lion of Lucerne — is threatened with destruction. The Lion, which was chiselled from the solid sandstone-rock by the Swiss artist Aborn, in 1792, commemorates the massacre of the Swiss Guard during the French Revolution, and, as a work of art, is unique. It is situated in rather damp surroundings, above a pool in the glacier-garden at Lucerne, and the water has trickled through the sandstone, which threatens to crumble, and thus destroy the statue. An expert has been examining the rock, and by his advice it has been decided to cut away the surrounding rock and isolate the Lion. — *Geneva Correspondence London Chronicle.*

[Aborn may have cut the stone, but the Lion was modelled in 1821 by Thorwaldsen; the Swiss Guard was massacred in 1792, and the memorial was not a ready-made one. — EDS.]

American Bridges, beautiful and ugly. — We have only to look at the bridges of Paris, of London, of Berlin, to see that good bridges are the rule rather than the exception in European cities, and that eminent beauty and monumental character, as illustrated by some of the newest structures, are compatible with the latest achievements of engineering in metallic construction. On the other hand, when we look at our American cities, we shall see good bridges a rare exception. New York, for example, has but one good bridge of note, in the strict acceptance of the term — Washington Bridge over the Harlem. The High Bridge, close by, is part of an aqueduct. Chicago, whose river gives it a superabundance of bridges, outside of its parks has not a single one worthy of the name. Boston is another city of bridges, but most of these are inexpressibly mean affairs. In the parks, to be sure, Boston has many bridges of striking beauty, representing a remarkable variety in design. One — the Longwood Avenue Bridge, spanning the idyllic stream of the Riverway with a noble great arch — is for ordinary traffic rather than for park purposes. Some of the most deplorable of Boston's bridges cross the great channel which the railway-tracks cut through the heart of the city. Of these, the Dartmouth Street Bridge in particular, hard by Copley Square and the Public Library and against the rich façade of the Back Bay railway-station, is so aggressively offensive, with its steel trusswork of an excruciatingly distorted shape, that any expense would be justifiable to secure its replacement with something unobtrusively worthy of the site. But the tide in Boston appears at last to have turned toward the construction of good bridges. A handsome new bridge for combined parkway and ordinary traffic across the Neponset is one token of this tendency, but the most significant instance is that of the great new bridge to Cambridge under construction across the Charles River. Particular pains have been taken to give a monumental character to this bridge, which has received, prospectively, the name of the most beautiful in the United States. — *Sylvester Baxter on "Art in Public Works" in the October Century.*

The Silver-leaf Poplar. — The immense demand for paper and the great quantity of wood used in making pulp call for the replanting, with some hardy, quick-maturing tree, of the acres denuded by this industry. A future crop of wood must be assured. The silver poplar, or abele, an importation from Europe, now become wild in this country, will answer this purpose well. It is found in every great city and is almost the only shade-tree that will survive the numerous vicissitudes of city life. The suckering is a nuisance in the city, but helpful for planting. The tree frequently surrounds itself with several thousand sprouts suitable for forest planting or it may be grown from cuttings of the branches or of the roots. The silver-leaved poplar is of rapid growth under favorable conditions. It will flourish upon the mountain-slopes of the Eastern States, increasing from three-fourths to one inch in diameter yearly. The wood is white and similar to that of the cotton-wood. There are many places where it would serve a good purpose for lumber. In 20 years there may be grown from 50,000 to 60,000 feet b. m. of lumber per acre from the abele — estimating 170 trees per acre, 20 inches in diameter and 20 foot length of trunk, which it is capable of attaining. Or considering it for pulp-production, there would be 6,500 to 7,000 cubic feet of wood per acre. — *Boston Transcript.*

An old Brown Cedar. — Charles E. Bessey, of the University of Nebraska, writes to *Science* of a cedar which he asserts to be over 1,000 years old, as follows: — "In the Garden of the Gods, near Pike's Peak, Colorado, there are many large specimens of the brown cedar, *Juniperus monosperma* (Engelm.), Sargent, and in a recent visit to that place it occurred to the writer that these trees must be very old. On the 13th of August he was fortunate enough to find the stump of a recently cut tree, on which it was easy to distinguish the annual growth-rings. These were counted for a section of the trunk, care being taken to select a portion in which the rings were of average thickness, and on this basis the number for the whole stump was calculated. In this way it was found that this particular tree was between 800 and 1,000 years old. In other words, this tree was a seedling some time between the years 900 and 1100 A. D."

The Archæological Value of old Cottages. — Some of the most precious finds that have ever fallen to the lot of the antiquary and collector have been in connection with small cottage-houses in the country, the sites of which have been near old ruined castles, abbeys and mansions. As such ancient buildings fell into decay in times long past, the materials of which they were composed and the very furniture and fittings within them were utilized by humble people for the construction of dwellings, and in this way relics of the past that are well-nigh priceless have been found in the walls and woodwork of laborers' cottages. Some of the most beautiful colored-glass of a very early period known to English collectors was found in a cottage near Ripon, in Yorkshire, and the very leaden frames in which the glass was embedded were unique and of great value to connoisseurs. Both glass and leaden frames are supposed to have come from Fountains Abbey, near to the cottage in question. In another case, not far from Pontefract, the stones of a humble cottage were found to have upon them many names rudely carved. As the cottage was itself a tumbled-down affair, it was levelled to the ground by the owner, and antiquaries then determined that the stones, with the inscriptions upon them, had come from an ancient castle. The names were those of Cromwellian and other soldiers for the most part, but some of the carved names were evidently those of prisoners of a much earlier period. Some of the most beautiful specimens extant of ancient woodwork have come from ancient cottages, but in all cases the latter have stood at some point near an ancient castle or abbey. — *London Tit-Bits.*

A Cedar-forest whittled down. — The cedar-factory at Greenville, Ala., is no more. For more than ten years it has been one of the most important industries in the South. It was built by some Richmond, Va., people, who found a little bucket-factory there and turned it into a big concern for making the little slats out of which lead-pencils are constructed. They built their own railroad out to Cedar Creek, where the timber grew, and gave employment to some 700 men, women and children. Now the cedar-timber is all gone, made into pencils, and ultimately whittled away by jack-knives of 70,000,000 people who have been sharpening pencils through the last decade. The timber being exhausted, the factory moves on to Mobile, where fresh supplies can be floated down the rivers and creeks from the interior. — *Boston Transcript.*

Sur le Tapis. — "On the carpet," again. Without any wish to charge so brilliant an author with the offences of her times we are compelled to observe, in the same book, that absurd carpet spread once more for the discussion of affairs. "Le tapis," on which things have been talked over in French literature, is — need we say? — not a carpet, but a table-cover; in fact, the green-baize table-cover of diplomatic convocation. On that are laid the papers, the protocols. A tapis is a carpet only when it covers the floor. Paper-hangings are called *tapisserie*, but even the English haste to burlesque (with an eye to "quaintness") the idioms of the stranger has not led our authors to speak of carpeting French walls. Would that "jumps to the eyes" and "it goes without saying" might be suppressed forever in English; but, at any rate, they are correct translations; whereas, "on the carpet" is not. — *London Chronicle.*

Experiments on Steel in Concrete. — By recent experiments to discover whether steel imbedded in concrete suffers any injurious changes, conducted by M. Breuillié, and described by him in the *Annales des Ponts et Chaussées*, it has been proved that steel does undergo certain changes. The paper on the subject shows that a salt is formed by the action of the cement on iron, also that this salt is dissolved by the water which penetrates into the concrete-steel. According to this action of the cement on the steel, it has been proved by experiment on ten 2″ x 2″ plates, that the weight of steel must undergo a change; it will be more or less "according as the newly-formed body adheres to the steel or not." An analysis of the plates was made, and an increase of weight was found, due to the formation of a silicate of iron. The tables given in the article of Mr. Breuillié indicate a regular increase in the weight. The author says: "If a soluble salt had formed, the plates taken out from the mortar should lose weight under the action of water. Nos. 46 to 50 were twice put in constantly renewed water, and they lost part of their weight. After 6 hours the loss of weight was on an average 2 milligrammes; after a second immersion of 7 hours the loss was 2.2 milligrammes. The salt which is formed at the contact of steel to cement seems to have an effect on the adhesion of the two bodies. To discover this point the author decided to find out whether the adhesion takes place on the setting of the cement, or whether it increases with age, as the salts do. The experiments made on thirty plates $1\frac{3}{4}'' \times 2\frac{3}{4}''$, placed on a horizontal surface of a concrete block, and then torn off after 2 to 5 days' intervals, showed that the adhesive increased uniformly, and cracked after 30 days. The above experiments convinced the author that (*a*) the cement attacked the iron; (*b*) water dissolved the composition which formed at the contact of the two materials; (*c*) the adhesion of the steel to the cement disappeared when water passed through the concrete-steel for a certain time; (*d*) the weight of the iron salts which adhere to the steel, and the normal adhesion between the steel and concrete increased with the time. Up to this time it has been thought that steelwork imbedded in concrete is not injuriously affected. These experiments certainly tend to disprove the assumption.

Wedgwood and its Maker. — What a debt of gratitude the world owes to the energy, enterprise, and rare artistic taste of Josiah Wedgwood, who more than any other made the sculptor's art familiar to every household — made it possible, as Prime says, for workmen in English shops and laborers in the field to use for buttons and ornaments gems of the glyptic art of the best ancient artists. It was a fortunate inspiration when Wedgwood overcame his modesty in regard to his achievement and presented in 1762 a candle and breakfast service of his cream-colored ware to Queen Charlotte, who was so enthusiastic over the soft ivory tint of the paste, the delicacy of decoration, and beauty of shape that she ever after gave him her patronage and bestowed the name of "Queen's Ware" upon this rarely beautiful product of Etruria. The recognition ensured his popularity and success, enabling him to carry out many plans which he had before been unable, financially, to mature. One of his happiest inspirations was the engagement of Flaxman, the portrait-medallions of the factory being chiefly cast from the latter's models, also the classical cameo-like decorations of white porcelain biscuit which adorned the early Wedgwood. Meantime, says the *Delineator*, such is the reward of genius — this second Phidias worked for about a guinea a day. Wedgwood had much to do, both directly and indirectly, with the "porcelain mania." His gift to Charlotte resulted in a royal penchant for objects of virtu, imitated by her subjects and inherited by her daughters, particularly the Princess Elizabeth, who is chronicled as begging her mother to go to Strawberry Hill, where she declares she spent a morning after her own heart among its china and other treasures. Histories may stand unopened upon the library-shelves, but bring out the "Landing" pitcher with its rich blue, and the gallant Lafayette seems to step into the group gathered around it. "I caught a glimpse of him as he passed down Genesee Street," says one. "My grandfather shook his hand," says another. "My great-great-grandfather fought by his side," proudly declares a third, recalling his bravery, his affectionate remembrance of those who shared danger with him as exemplified in his kneeling to kiss the curb above a comrade's grave, with the touching remark: "Ici repose un cœur noble." — *Philadelphia Press.*

NOTES AND CLIPPINGS. 32

ONE of the most interesting public documents ever issued is Mr. Carroll D. Wright's report on the anthracite-coal strike, which forms the most important portion of the November Bulletin of the Department of Labor. In this admirable paper Mr. Wright appears at his very best, as an experienced and considerate official, skilful in ascertaining the truth, and ready to do justice to both sides. As those who have read the newspaper accounts of the statements of both sides will readily infer, the trouble is, apparently, due, in great part, to prejudice and misunderstanding, on the part of the operators as well as of the miners. As Mr. Wright shows, the dissatisfaction of the miners is to be attributed, in a considerable degree, to petty injustices and oppressions on the part of foremen and overseers, and, even of these, many are unintentional, and are to be attributed to the ignorance, on the part of the miners and the foremen, of each other's language. Overseers of this class are notoriously disposed to be unreasonable and tyrannical, and any one who has seen an Irish foreman bully a squad of Italian laborers can easily imagine that a gang of Italian, Hungarian and Russian miners, incapable of understanding their overseer, or of making themselves understood by him, would soon lay up a long list of grudges against a foreman of the ordinary type. In the mines, the case is made worse by the fact that deduction is made from the miners' wages for stone in the coal that they get out; and, as this deduction is, apparently, left wholly to the judgment of the overseer, it is, naturally, impossible to avoid some appearance, at least, of oppression and unfairness. If the operators were willing to interest themselves in the working of their own mines, and show themselves ready to listen to complaints, and to remedy injustice, Mr. Wright thinks that they would get loyal and faithful service in return; but they choose, apparently, to take the attitude that their men are their slaves, and talk about "discipline," exactly as a Southern planter, before the Civil War, would have discussed the problem of keeping unruly negroes in subjection; while, unlike the Southern negroes, whom their master was obliged to feed and clothe at all times, the anthracite miners are liable at any time to be turned adrift, by the closing of the mine, without any explanation, and, so far as they can tell, simply at the caprice of the operators.

IT is not surprising that this method of carrying on the business of anthracite mining should have brought about a state of things in which, as Colonel Wright says, "suspicion lurks in the minds of every one, and distrust in every action on either side"; and it is obvious that the operators, as the more intelligent class, are chiefly to blame for this. Under such circumstances, the idea of organizing the miners was brought forward, and here, again, a worse misunderstanding than ever arose. To the more sensible miners, and to a great many intelligent persons who, although not engaged in the business, were familiar with the conditions, it seemed as if an organization of this sort would enable the operators and their men to make definite agreements in regard to disputed points, such as the percentage to be deducted for rock, the standard size of car to be loaded by the men, and other matters, about which there was constant, and not entirely unreasonable, dissatisfaction; and it was thought probable that such an organization would be an effective means of keeping in order the ignorant foreign miners, who have no idea of the meaning of a contract, and rebel against the control of the foremen, whom they regard as their natural enemies, but whose loyalty to their fellows, which is a strong feeling among them, would lead them to obey the mandates of their own organization. There is a good deal to be said in favor of this view, but the operators jumped at the conclusion that an organization of this kind would destroy discipline; that its agreements would not be respected, and that it would be managed by the worst elements among the men. It is possible that all these results might follow the association of the anthracite miners, but it is, to say the least, not proved that they would do so, and the miners, who seem to have had a high ideal of their proposed organization, conceived the notion, which, from their point-of-view, was as reasonable as that of the operators, that the latter did not wish to make any agreement with the men, for fear of limiting the caprice and tyranny which the men attributed to them. This was exactly the state of things which a little courtesy and fairness might have brought to an amicable conclusion, and the operators are certainly to blame for not being willing to show these virtues. According to Colonel Wright, the conditions which the men ask for are not unreasonable. The operators say that if the demand of the miners for increased pay is granted, the cost of anthracite coal to the public will be increased sixty cents a ton. Fortunately, the public is quite aware that the price of coal is regulated, not by the wages paid to miners, but by what those who want the coal are willing to pay for it; and, as a matter of fact, Colonel Wright says that what the miners want is not so much an increase in their wages for the time that they work as relief from that curse of American industry, enforced idleness. He says, no doubt with reason, that "if the men could be sure of steady work, or fairly steady work, they could well afford, perhaps, to take less wages, or even to continue on the present basis of payment"; and it is understood that many of the men take this view. It is hardly necessary to point out that an increase in the number of days during which the men work would, naturally, result in an increase in the output of coal, and, presumably, in a reduction of the price; so that the interest of the public accords in this respect with that of the miners. Even the operators need not, it would seem, view this contingency with alarm. As they say, the wages paid to the miners for getting out coal form a small part of its cost, the rest being made up of interest payments, maintenance of machinery, expense of pumping, salaries of overseers and officials, and many similar items, which accumulate just as rapidly when the mine is worked six days in the week as when it is worked only four; and the obvious inference is that if the miners were employed continuously, instead of intermittently, the cost per ton of the coal produced would be much less that it is now, and the operators could, with profit, sell it to the public at a lower price, at the same time that they improved the condition of their men. All these points might properly, and with advantage, be investigated by an impartial commission; and, while there is, undoubtedly, much truth in what the operators say of the folly and tyranny of the unions, it may be presumed that such a commission would appreciate unreasonableness on the part of the miners, as well as on that of the operators.

THE Insurance Engineering Experiment Station has issued a Report, Number Four of its series, on the Corrosion of Steel Frames of Buildings, which is the most important contribution to the science of building which has appeared for many years. We need not say that, although many millions of dollars are expended upon steel-frame construction every year, no one has yet been able to give convincing proofs that buildings of this construction would last through more than one generation; and the warning of a very distinguished engineer, that, judging from his experience, few of them would reach their twentieth birthday, has never yet been met with anything better than mere assertion, unsupported by rational evidence. Under these circumstances, the Experiment Station undertook the task, not of testing steel frames under conditions exactly

Entered at the Post-Office at Boston as second-class matter

similar to those to which they would be subjected in actual buildings, for the obvious reason that such a test would require several years' observation, but of imbedding structural steel in masonry, similar to that used in this system of construction, and exposing it to the action of moisture and carbonic acid in a more energetic form than that in which they present themselves in an ordinary atmosphere. As it is generally admitted that carbonic acid and a moist atmosphere are the active agents in corroding steel, the problem resolved itself into applying these agents in a concentrated form, so that their effect would be visible within the few weeks which could be devoted to the experiment; and, for this purpose, mixtures of steam and air, air and carbonic acid, and steam with carbonic acid and air were employed.

THE steel to be tested was in the form of expanded-metal lathing, steel rods, and sheet steel. In order to avoid error in consequence of spots of rust on the metal, which, in the opinion of many engineers, continue to increase under a covering which would efficiently protect clean metal, all the pieces of steel used were first scoured, then "pickled" in hot dilute sulphuric acid; after which they were dipped in hot milk of lime, to neutralize the acid, and the lime finally removed with a wire brush. This treatment left the metal perfectly free from rust. The pieces were then imbedded in concretes of various kinds, made with Alpha and Lehigh Portland-cement, mixed with sand, broken stone or cinders in different proportions. The concretes were formed into blocks, or briquettes, each briquette with a piece of metal buried in it; and in all cases the concreting materials were mixed dry, again mixed after adding water, and thoroughly tamped. Two briquettes were made of each mixture. In all, several hundred briquettes were made, and were exposed to different artificial atmospheres, as well as to the ordinary air of the laboratory; and, besides the briquettes, pieces of unprotected steel were also exposed. After three weeks, the briquettes were cut open, and the imbedded metal carefully examined. In all cases, the unprotected metal was found so badly corroded as to be "more rust than steel." Of the protected metal, that which had been buried in neat Portland-cement resisted the trial best, every specimen, whatever the atmosphere to which it had been exposed, being taken from the briquette as bright as when it was put in. Of the other specimens, which had been buried in concrete of some sort, we are told that "hardly one had escaped serious corrosion," and it was found that "the location of the rust spot was invariably coincident with either a void in the concrete or a badly rusted cinder." In cases where the concrete was porous, the steel was "spotted with alternate bright and badly rusted areas, each clearly defined"; and it is interesting to learn that the specimens least affected, after those made with neat cement, were those in which the concrete had been mixed very wet, so that the almost liquid cement had splashed over the steel like paint, protecting the portions which it covered. Some subsequent experiments, suggested by this observation, showed that, by using finely ground cinders, concrete made even with two parts cinder to one part of Portland-cement could be so applied, presumably by mixing it very soft, as to protect the steel, provided there were no crevices or perceptible voids.

EXAMINATION of some specimens, brought in from outside, of expanded metal embedded in concrete, showed that wherever the concrete was cracked, the steel began to rust, even though the cracks were very fine, indicating that the protecting cement, to be of service, must be in contact with the metal, a separation, even of a few one-hundredths of an inch, making it useless. In connection with this, Professor Norton, the author of the deeply-interesting report before us, says that he had recently occasion to examine some Z-bar columns, which were exposed in altering a metal-framed building five years old. The columns had been painted, and were simply built into the brickwork. The columns showed evidence of having been rusty when painted; and the moisture circulating between the brickwork and the metal had penetrated the paint, and caused the rust to increase, so as to split off the paint. It is probable that, if the steel had been perfectly clean when it was painted, the paint would have protected it for much more than five years. How long it would preserve it no one can say; but Professor Norton points out that, if the paint should disintegrate and disappear, it would leave a void next the metal, "the worst possible condition." He therefore much prefers a thorough wash of cement, applied directly to the clean steel, to any paint; but he says that "if, as is often the case, the choice is between paint and rust which accumulates during construction, the paint is to be preferred." The conclusions which Professor Norton draws from these experiments are that "neat Portland-cement, even in thin layers, is an effective preventive of rusting"; that "concretes, to be effective in preventing rust, must be dense, and without voids or cracks"; and "should be mixed quite wet when applied to the metal"; that "the corrosion found in cinder concrete is mainly due to the iron oxide, or rust, in the cinders, and not to the sulphur"; that "cinder concrete, if free from voids, and well rammed when wet, is about as effective as stone concrete in protecting steel"; and that "it is of the utmost importance that the steel be clean when bedded in concrete. Scraping, pickling, a sand-blast and lime should be used, if necessary, to have the metal clean when built into a wall."

WE have quoted more freely, perhaps, than we ought from a paper which is the property of the Insurance Engineering Experiment Station, but its extreme importance, and the urgent need of placing its conclusions before the profession at the earliest possible moment, will, we hope, be received as a sufficient apology. Meanwhile, as the Experiment Station invites suggestions from architects in regard to these matters, we would like to observe that as anything like pickling is out of the question with structural members, not only on account of the impracticability of dipping ten-ton girders, or thirty-foot columns, in hot sulphuric acid, but, still more, on account of the certainty that some of the acid would creep in between the plates, or under the rivets, out of reach of a lime wash, and there cause destructive corrosion, those who have every day to write specifications for the treatment of structural steel would like very much to know of some more practicable method of securing an approximately similar result. Professor Norton advises, besides pickling, scraping and sand-blast cleaning. The sand-blast would not be much easier of application than the pickling; but scraping is not difficult; or, as in our own practice, the steel can be cleaned quite effectually with a stiff wire brush. With either scraping or the wire brush there will still, however, be left traces of rust, particularly in the joints, and it seems possible that a thin alkaline wash might render them harmless, without involving the difficulty and danger of acid pickling. The milk of lime, which is only feebly alkaline, and is too thick to penetrate the crevices where rust would be likely to hide, could hardly be depended upon for this purpose, but it seems possible that a dilute solution of silicate of soda, followed by a lime wash, might be effective, and such an application would be quite within the capacity of the ordinary iron shop. As architects cannot often make chemical investigations for themselves, we hope that the Experiment Station may find disposition and opportunity to study this development of the subject; and the practice of the old New York builders, who, in the days when structural steel was left exposed, always whitewashed their "Cooper beams," or their "Harper girders," before painting them white, to prevent staining from the corrosive action of white lead on the iron, may, possibly, suggest some alkaline application which could be put on at the rolling-mill, before the painting which is necessary to prevent rusting in transportation and from storage in open yards, and which would, after the paint was scraped off with a wire brush, leave a clean surface, or, if the paint should not be scraped off, might resist even the action of moisture from masonry in contact with the paint.

ANOTHER point which the Experiment Station might study with great advantage is the behavior of structural steel surrounded by masonry other than concrete. The only example of this sort which Professor Norton refers to is the rather alarming one of the Z-bar column built, five years before, into brickwork, which had rusted so much as to throw off the paint. As, in practice, the most important members in a steel frame are surrounded by brickwork or stonework, not by concrete, the question of protecting them in that situation is a most urgent one. We may say that, in our own practice, all vertical members surrounded by brick or stone masonry are grouted every foot in height, as the brickwork is carried up around them, with liquid cement; and some architects accomplish substantially the same result by plastering the vertical members before building up the masonry around them; but these precautions are not usual. Judging from Professor Norton's experiments, they seem to be desirable, but it would be interesting and important to know how effective they are in preventing corrosion, and whether there is any better way of protecting such members.

THE AMERICAN VIGNOLA.[1]—X.

PART I.—THE FIVE ORDERS.

INTERCOLUMNIATION, OR THE SPACING OF COLUMNS.

THE space between two columns, measured just above their bases, is called an *Intercolumniation*. It is one Diameter less than their distance apart on centres, or on edges.

Columns are said to be *Coupled*, or to have a *Pycnostyle*, *Systyle*, *Diastyle*, or *Areostyle* Intercolumniation, according as they are set close together, or are one, two, three or four diameters apart, as nearly as may be, i. e., about one, two, three, four or five Diameters on centres. The Systyle and Diastyle are the most usual, with an Intercolumniation of two or of three Diameters.

But Coupled columns cannot be nearer than $1\frac{1}{3}$ D. on centres, instead of 1 D., on account of the projection of their bases, and in the Ionic, Corinthian and Composite Orders, not nearer than $1\frac{1}{2}$ D., on account of the projection of their Capitals. The Intercolumniation of Coupled Columns is accordingly $\frac{1}{3}$ D., or $\frac{1}{2}$ D., or even a little more, to prevent the Bases or Caps from actually touching.

So also the Pycnostyle Intercolumniation is made $1\frac{1}{4}$ D., instead of 1 D. (i. e., $2\frac{1}{4}$ D. o. c., instead of 2), to avoid crowding. The ancients thought that even the Systyle columns with an Intercolumniation of two Diameters, came too near together, and preferred what they called the *Eustyle* Intercolumniation, of $2\frac{1}{2}$ Diameters (or $3\frac{1}{2}$ D. o. c. in place of 3 D.). But the moderns prefer to make the Eustyle Intercolumniation $2\frac{1}{3}$ D. (setting the columns $3\frac{1}{3}$ D. o. c.), as this brings every Column in Ionic and Corinthian colonnades exactly under a Dentil, and every alternate one just under a Modillion, the Dentils being $\frac{1}{6}$ D. o. c. and the Modillions $\frac{2}{3}$ D.

The wider Intercolumniations are preferable, obviously, when the columns are small, since otherwise it might be difficult to pass between them, and the Systyle, or even the Pycnostyle, when the columns are very large, since otherwise it might be difficult to find stone architraves long enough to span the interval. But the ancients used Tuscan Columns chiefly with wooden architraves, setting them as much as seven Diameters apart, which is called the *Tuscan Intercolumniation*, and which makes the space between the columns about square. In modern times also, an arrangement of coupled columns has been employed, called *Areosystyle*, the columns being set half a Diameter apart, and the space between the pairs of columns made $3\frac{1}{2}$ Diameters. This is greater than the Diastyle Intercolumniation and less than the Areostyle by half a Diameter. From the axis of one pair of columns to that of the next pair the distance is six Diameters. If in a Systyle Colonnade, with the columns three Diameters on centres, the alternate columns are moved along till they nearly touch the intervening ones, the result is an Areosystyle Colonnade. This was first used in the Eastern Colonnade of the Louvre (Fig. 151).

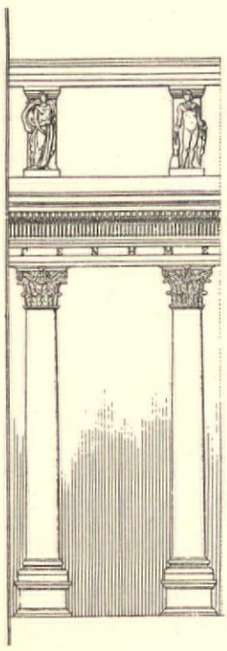

Fig. 150.

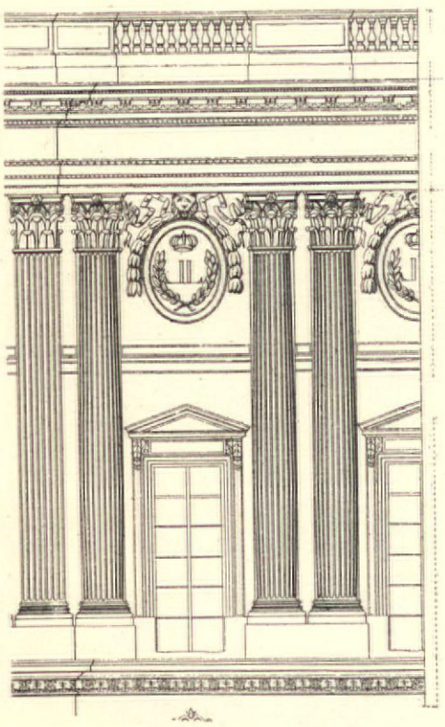

Fig. 151.
Colonnade of the Louvre.

In actual practice these rules for Intercolumniation are seldom exactly followed.

DORIC INTERCOLUMNIATIONS.

In the Doric Order, since the Columns come exactly under the Triglyphs and the Triglyphs are $1\frac{1}{4}$ D. o. c., as on edges (the width of the Triglyph being $\frac{1}{2}$ D. and that of the Metopes $\frac{3}{4}$ D.), the distance of the Columns on centres must needs be a multiple of $1\frac{1}{4}$ D.

This makes the coupling of Doric Columns difficult, since, even if the Bases touch, the distance between axes is still $1\frac{1}{3}$ D., which is more than that of the Triglyphs by $\frac{1}{12}$ D. This slight discrepancy can, however, be got over by making each Base a trifle narrower, or the Triglyphs and Metopes a trifle wider, or by putting the Columns *not* exactly under the Triglyphs, or by employing all these devices at once.

If the Columns are set under alternate Triglyphs so that there is one Triglyph over the intervening space, their distance apart o. c. is $2\frac{1}{2}$ D. The Intercolumniation is then $1\frac{1}{2}$ D., and is said to be *Monotriglyph*. This is the most common arrangement. But if the scale is small, it is usual, at least at the principal entrance of a building, to have two Triglyphs over the opening, the Columns being $3\frac{3}{4}$ D. on centres. The Intercolumniation is then $2\frac{3}{4}$ D., and is called *Ditriglyph*. Still wider spacing is employed when the Architraves are of wood.

When two, four, six, eight, ten or

[1] Continued from No. 1394, page 85.

twelve Columns are used, in a Colonnade or Portico, it is said to be *Diastyle*, *Tetrastyle*, *Hexastyle*, *Octastyle*, *Decastyle* or *Dodecastyle*, according to the Greek numerals. Examples are found at Argos, Assos, Thoricus and Pæstum of façades with an odd number of columns, three, five, seven and nine, a column instead of an intercolumniation coming on the axis, giving tristyle, pentastyle, heptastyle and enneastyle porticos. But in most of these cases the entrances were on the sides of the buildings, where there was an even number of columns.

SUPERPOSITION.

Superposition is the placing of one Order above another, as in the Roman Amphitheatres and in many modern buildings of several stories. The more solid forms of the Tuscan and Doric are naturally placed below, and the Ionic and Corinthian above. The Composite is sometimes placed below the Corinthian, as being more vigorous. But in high buildings it is generally placed on the top story, its large details being better seen at a distance than are those of the more delicate Order.

Even when the same Order is employed in the different stories it is advisable to have the upper Columns of smaller diameter than those below, and all the dimensions diminished accordingly, for the sake of lightness. But it is still more so when different Orders are superposed, for otherwise the Doric and Corinthian stories would overpower the Tuscan and Ionic ones beneath. It is usual, accordingly, to make the lower diameter of each Shaft equal to the upper diameter of the Shaft below it, as if they were all cut from a single piece of tapering stone. This makes the scale employed in the second story five-sixths of that used in the first; in the third, twenty-five thirty-sixths, or about two-thirds; in the fourth, about three-fifths, and in the fifth, about one-half, if the Five Orders are employed in regular sequence; this makes the relative height of the Orders in the successive stories to be as 7, $6\frac{2}{3}$, $6\frac{1}{4}$, $5\frac{5}{6}$ and 5, very nearly. The actual height of the stories themselves may be somewhat modified by the use of plinths and pedestals.

This system of Superposition makes the distance apart of the Columns in each story, when expressed in terms of their own Diameter, six-fifths of that in the story below. A Eustyle Intercolumniation in one story thus exactly produces a Diastyle Intercolumniation in the story above, and a Doric Monotriglyph Intercolumniation, a Systyle.

($\frac{6}{5} \times 3\frac{1}{3} = 4$; $\frac{6}{5} \times 2\frac{1}{2} = 3$.)

Coupled Columns set $1\frac{1}{3}$ D. apart, on centres, in one story, are, in the story above, $1\frac{3}{5}$ D. o. c., and in the third story nearly 2 D. o. c. This does very well for a sequence of Doric, Ionic and Corinthian (152). But if the lower Columns are Ionic or Corinthian those above may well be set nearer together, the axis of the Intercolumniation only being preserved (153).

With this exception Superposed Columns are set so that their axes are in the same vertical line, when seen in elevation. But in profile, as seen in section, the upper ones are set back, the wall against which they stand generally growing thinner as it goes up (154). Since the Columns themselves also grow smaller, it would not do to leave too much space behind them. The slightly pyramidal effect which this gives to a building of several stories is of great value, preventing it from looking top-heavy and high-shouldered.

OTHER CORNICES AND STRING-COURSES.

The Five Orders worked out by Vignola are generally accepted as a standard, though they are seldom exactly followed in practice, modern as well as ancient examples exhibiting a great variety in the forms and proportions of the parts. But familiarity with them is of great service in designing, since they can safely be employed on all ordinary occasions, and in the earlier stages of architectural composition. Other types of nearly equal merit have been published by Alberti, Palladio, Serlio, Scamozzi, Sir William Chambers, and others, and a great variety of cornices, both with and without friezes and architraves, have been employed in ancient and modern times to crown and protect walls that were not decorated with columns or pilasters.

Many of these show Blocks or Modillions without any Dentil-course below, as on Palladio's Composite Cornice, and in many of them the Dentil-course is plain, forming what is called an *Uncut* Dentil-course (155). In others the brackets which support the Corona are brought down so as to occupy the Frieze (156). The most important

of these is Vignola's so-called *Cantilever Cornice* used by him at Caprarola (157). It seems to have been suggested by the Mutules and Triglyphs of his Mutulary Doric.

Cornices, and indeed full Entablatures, are often used as String-courses to separate stories, as in the Roman Amphitheatres. But it is customary to use, instead, a lighter form, of small projection, somewhat like the cap of a pedestal, in which the Cymatium and Bed-mould are often omitted, and the Corona itself sometimes diminished to a mere fillet (158 to 162).

ERRATA.

Vol. LXXIII, No. 1341, September 7, 1901; page 75, right-hand column, twenty-fourth line from the bottom: for "Mutules," read "Metopes." Page 76, right-hand column, lines eighteen, twenty and twenty-one from the top: for "degrees," read, "of a Diameter."

Vol. LXXIV, No. 1352, November 23, 1901; page 60, right-hand column: omit lines fifteen, sixteen, seventeen and eighteen from the bottom.

Vol. LXXVII, No. 1390, August 16, 1902; page 51, left-hand column, ninth line from the bottom: read, "a Regula as broad as the Triglyph." Page 53, left-hand column, eleventh line from the bottom: for "dentils," read "details."

Vol. LXXVII, No. 1394, September 13, 1902. Page 83, right-hand column, at the end of the third paragraph: for "three," read "two." Page 84, right-hand column, fifth line from the top: for "one-fourth," read, "about one-fourth."

Plates of the Doric Order; $\frac{7}{8}$ *D* at the top of the Capital should show the width of the Abacus, not that of the moulding which crowns it. For "$\frac{3}{4}$ *D*" above the Cymatium, read "1 *D*."

Plate of the Composite Order; for the height of the lower band of the Architrave in Palladio's Order, read "$\frac{2}{3}$" instead of "$\frac{1}{3}$."

W. R. WARE.

[The end.]

URALITE.

A DETAILED description of the new fire-resisting material uralite, invented by a Russian artillery-officer named Imschenetzky, is given in an interesting report made to the State Department by Consul-General Hughes, of Coburg. The substance is said to be virtually waterproof, is not affected by atmospheric conditions, and is a non-conductor of heat and electricity. It can be cut like wood with carpenters' tools, painted, grained, and polished, and is available for many purposes of interior construction and decoration. Mr. Hughes says that uralite is an asbestos fibrous substance, composed of asbestos-fibre, silicate, and bicarbonate of soda. It can be prepared hard or soft and used in a variety of ways. The process of manufacture, which is akin to that of paper-making, is given in full.

Mr. Hughes, in discussing the fire-resisting qualities of uralite, quotes an expert who speaks thus regarding some suggestive tests: "Three principal tests were made, and they fully proved that the material possesses the following qualities: (1) It is able to withstand intense heat for a long time without disintegration; (2) its non-conducting powers are uniform throughout; (3) it is capable of entirely preventing the passage of flame from any room where fire occurs; (4) after prolonged exposure to fire, it is able to resist water without serious damage; (5) exposure to changing atmospheric conditions does not effect it; (6) all the materials employed in its manufacture possess substantially the same chemical, physical, and thermal constants. In order to carry out the tests, a small brick-built house, an iron-framed hut, lined and covered with uralite, and a duplicate platform were erected. Each of these was fitted with pyrometers, recording the temperatures electrically, and was filled with highly inflammable materials. In the case of the platforms, the materials were distributed evenly under the two sections. To the test-house were attached four doors. One door was constructed with two oak boards $\frac{3}{4}$ inch thick. Next to the timber was a thin steel armor-plate, and over all was a covering of uralite. The second door, suitable for inside use, was built of two sheets of hard uralite running through the centre of the door and forming panels. The framework consisted of timber laid on either side. A door for warehouse purposes consisted of a thickness of soft uralite in the centre and oak on either side. Next to the timber was fixed a thickness of soft uralite, and the whole was covered by a layer of hard uralite. The stiles of the other door were constructed of oak, $1\frac{1}{2}$ inch thick, and the panels were filled-in with uralite cement. The timber was covered over with soft uralite, and on that a thin steel armor-plate was fixed. The whole was covered by hard uralite. In each case, the materials were fixed together by means of nails and screws.

"A fire was lighted inside the house and the doors were shut. The highest temperature reached was 2,350 degrees Fahr. After the test, it was found that in each case the doors had resisted the fire. It is interesting to note, however, that in the case of the second door practically all the wood outside was burned off, leaving the outer layer of uralite uninjured by the severe heat. The fire was left to burn for over an hour. In the hut was placed a deed-box made of the uralite and wood, and in the box were placed some papers, a book, a crucible containing paraffin-wax, and another holding a piece of easily fusible metal. After being subjected to an external heat of 2,030 degrees Fahr., the papers and book were not affected in the slightest degree. It was found that the wood nearest the fire was charred right through, but the middle layer of uralite was sound and the paraffin-wax had only melted slightly. The platform was 12 feet long and 6 feet wide, was built of wood, and but one-half was covered with uralite. After the fire had burned underneath it, and had reached 2,270 degrees Fahr., the unprotected portion was completely destroyed, but that covered with uralite was whole and strong and several of the visitors walked across it. After the fire in the small house had been going three-quarters of an hour, and when the pyrometer was registering 2,120 degrees Fahr., those present were able to place their hands in contact with any part of the door which was covered inside and out with uralite, though by this time the whole of the woodwork had been burned off the door which had uralite for its panels only.

"I afterwards witnessed some tests showing the crushing and breaking strain of the material. In the first, a cube 1 inch square, built up with sections, cut from standard sheets, was subjected to hydraulic pressure. A pressure of 19.8 tons was registered before they gave way. In the second test, a strip $9\frac{1}{4}$ inches long, $1\frac{1}{2}$ inches broad, and $\frac{7}{8}\frac{1}{4}$ inch thick was placed between supports and gradually subjected to an increasing weight placed at its centre. It did not break till a weight of 6 875 kilogrammes (just over 15 pounds) had been applied."

THE FABRIC FUND OF WESTMINSTER ABBEY.[1]

"AN insolvent Chapter and a ruinous fabric!" In such words, just twenty-one years ago, were his coming responsibilities described to the then newly-appointed Dean, Dr. Bradley, by one whose intimate knowledge of Westminster justified him in making so bold and discouraging an assertion — an assertion, moreover, in which it was only too quickly proved there was little exaggeration. There are probably few who remember, or at the time fully realized, the financial crisis through which the greatest of our national monuments had to pass between fifteen and twenty years ago.

Before the Dean who is now on the eve of his retirement had been a year in office, a report was brought to him by the architect and surveyor of the Abbey (the late Mr. J. L. Pearson) which aroused the gravest anxiety for the condition of the fabric. It was obvious that a very large expenditure was required, and without delay, to prevent the most serious results. How this expenditure was to be met was a matter difficult indeed for the Dean and Chapter to determine.

An Act of Parliament had been passed in 1868, followed by an Order in Council in 1869, by which the landed and other property belonging to the Abbey, much of which in the vicinity of London had increased enormously in value in the early years of Queen Victoria's reign, was finally transferred to the Ecclesiastical Commissioners. In accordance with a commutation or settlement then agreed upon, a certain portion of land and houses was made over to the Dean and Chapter, while another sum of equal amount in money was to be paid to them annually, a further sum of £20,000 being awarded for repairing the fabric. Unfortunately, however, the value of the lands assigned to the Abbey began rapidly to diminish after this settlement, a contingency which could not have been foreseen either by the Commissioners or by the representatives of the Chapter, who appear to

[1] Extracts from a paper by Miss Rose M. Bradley, in the *Nineteenth Century* for September.

have been at this time quite unaware of the real condition of the building, or of the constant and increasing demands which would be made for its repair upon the Abbey funds in the years that were to follow. And so it happened that in 1882 the revenues were scarcely sufficient to supply the reduced annual stipends of the officials. Fabric Fund, as such, there was practically none; and the Commissioners, however willing to readjust the settlement, had no legal power to do so, nor could they without fresh legislation assist the Dean and Chapter by an immediate grant. But neither could the Abbey be permitted to fall. In this dilemma an appeal to the country, and even to America, was suggested, which would no doubt have met with prompt response on both sides of the Atlantic. But the Dean felt strongly that the maintenance of a building of so exceptional a character should not be dependent upon the generosity of individuals, but should form a "matter of serious consideration to the Government and Legislature of the nation." And for six years the matter was very seriously considered, and much correspondence passed between the Dean (representing the Chapter), the Ecclesiastical Commissioners, and Her Majesty's Government. In 1886 an Act was passed authorizing a grant of £10,000 to assist the Dean and Chapter in remedying the "present insecure condition of the Abbey." In 1888 was passed the Westminster Abbey Act, followed by an Order in Council, by which a fresh and more satisfactory settlement was arrived at. The whole estates and property belonging to the Dean and Chapter, with the exception of the Abbey itself and the houses of the officials, were transferred to the Ecclesiastical Commissioners; they on their part to pay over an annual sum to the Dean and Chapter, sufficient for their necessary expenses, and a marginal sum to be set apart yearly as a Fabric Fund. As this latter could not in the existing emergency be sufficient, one of the six canonries was also suspended, and remains so to the present day. And so the work of repairing the Abbey was begun in serious earnest, and has been continued with little intermission for the last fifteen years.

In the light of these comparatively recent events it may be of interest to inquire why so great and national a church, linked by the closest of ties with Sovereign and people alike, should have had from its foundation no steadily accumulating fund set apart for its maintenance and what were the circumstances which led indirectly to so insolvent a condition.

From the completion of the first abbey church of Edward the Confessor in 1065 to the dissolution of the monasteries under Henry VIII in 1540, a period of five centuries, the erection and enlargement of the Abbey was mainly, though not entirely, the work of successive Kings. . . .

And through all these five centuries, which may be considered to form the first part of the history of the Abbey, whilst the building and beautifying of the church and monastery were in perpetual progress, no mention can be found of a Fabric Fund. What need, it may be asked, when the King in his palace close by was ever ready, not only to spend largely himself, but had decreed that the resources of the country must, if necessary, be drained to the uttermost for the enlarging and the embellishment of the burial-place of Sovereigns? What need again, when the Abbot, following the example of his royal master, could invariably obtain money by the easy impropriation of existing religious foundations, alien priories and tithes, as well as by other means alluded to above? Generosity of the hour was surely a pleasanter and more profitable virtue to practise than the dull forethought which would put by for a day when that same pile, now their boast and their glory, would crumble — a day which most certainly neither royal nor monastic builder would live to see. It must be remembered, moreover, that the question of repair and maintenance was less prominent during this period than that of construction. The buildings had not been exposed long enough to decay, nor was there a sufficient amount of coal-smoke in the atmosphere of mediæval London to be deleterious. And, most powerful reason of all, there was no feeling against demolishing the work of former generations in order to replace it with new buildings. Nevertheless, there is evidence that the *maintenance* and *repair* of the Abbey had occasionally been a heavy tax upon the community. . . .

Sovereigns continued for a time to erect tombs for themselves and their predecessors. But with the change of religion the bond between King and Church became necessarily less intimate, and the shrine of the sainted Edward the Confessor held less significance for his successors. . . .

The period of the Civil Wars was naturally a disastrous one for the Abbey; but previously, in 1603, on the accession of James I, we find an item in the Chapter Book which shows that an effort had been made in the right direction: "That provision shall be made of lead, stone, timber, and other necessaries towards the reparation of the Fabrik of the Church yearly, to the value of Forty pounds, layd up in the store house, not to be imployed without the consent of the Deane," and a further item which gives authority for the use of the same to "the Treasurer for the time being, with the consent of Mr. Deane," an order which is observed to the present day. Immediately after the Restoration, large fines having been received for leases, considerable sums were expended both in repairing and refurnishing the church, from which the ornaments had been carried off during the Great Rebellion. . . .

In 1624 we learn that one Christopher Tamworth gave £20 to the repair of Westminster Abbey; but it remained for Dean Dolben, appointed in 1662, to make the first genuine effort to establish a permanent Fabric Fund. He prevailed upon the Chapter to assign henceforth "a Prebend's share" (*i. e.*, one-fifteenth of the total annual income) "to be reserved and employed for the repairs of the Abbey," the roof and vaulting of which were said to be in actual danger. So much importance was very properly attached to this measure of Dean Dolben's, who afterwards became Archbishop of York, that to his long epitaph on his monument at York are added the words "*Cœnobio Westmonaster: Conservato.*" This practice of setting aside one-fifteenth, or a Prebend's share, was adhered to until the estates were handed over to the Ecclesiastical Commissioners in the last century. . . .

Year after year further sums were petitioned for and granted for the repair of the fabric, amounting between 1809 and 1822 to no less than £42,000. Dean Dolben's settlement of the one-fifteenth continued to be set aside, and was aided by the produce of all sales of timber, notably of the scaffoldings used for Coronations — a perquisite of which the Abbey can no longer boast — and of the fees paid for the erection of monuments. In pursuance of an Act of Parliament in 1840 the number of Canons was reduced from twelve to six, and in 1868 Westminster School, by the Public Schools Act, ceased to be a part of the establishment of the Abbey, and no longer demanded the repair of its buildings from the Chapter. Matters did not improve, however, even with the rapidly increasing value of the London property, for while the stipends of the Chapter became disproportionately large, no definite sum was set aside towards the Fabric Fund. With the commutation of 1869 even Dean Dolben's modest allowance ceased to exist. It needed, as we have seen, another Act of Parliament and strenuous efforts on the part of the custodians to establish at all events the foundations of a permanent working Fabric Fund, and to save from ruin the last resting-place of those who through ten centuries have contributed, whether as Sovereign or subject, to the greatness of our Empire. For the present Westminster Abbey is saved; but its history, even as given in these few pages, is full of warnings of the absolute necessity for unceasing watchfulness on the part of those entrusted with the care of buildings exposed through a long series of years to the action of a London atmosphere.

ZIMBABWE RUINS.

THE secret of the ancient ruins of Zimbabwe, with its acropolis, temple and forts, has not yet been laid bare. It is still uncertain to whom we owe these mysterious structures and at what date they were erected. A very good case has been made out for identifying Zimbabwe as the Havilah of the Old Testament, and for supposing that Phœnicians or descendants of Phœnicians had a hand in its erection. One thing is certain: that the buildings are not the work of any of the present natives of South Africa, although they may have been used over and over again by local tribes. Native implements found in the ruins prove this. Perhaps the greatest puzzle is the *raison d'être* of the situation of the ruins. The acropolis is situated on a kopje 250 feet high in a plain surrounded by hills, and affording an extensive view along several valleys. The temple is situated in this plain, and down one of the valleys there is a long chain of forts striking eastward as if making towards the coast. The curious part is that there are in the immediate vicinity none of the ancient gold-workings which abound all over South Rhodesia, and there still exists the unsolved problem of the situation of Zimbabwe.

Perhaps in the near future the truth may be disclosed. The Government of South Rhodesia, says the *Scotsman*, have taken a very important step for the preservation of the ancient ruins. They have appointed Mr. R. N. Hall, who is joint-author with Mr. Neal of "*The Ancient Ruins of Rhodesia*," as temporary curator of Zimbabwe. It is to be his work to clear away all rubbish and vegetation that tends to conceal or to destroy the buildings. Mr. Hall arrived at his station on May 23 and already a great amount of work has been done. The walls enclosing passages which wind round and up the kopje to the enclosures on the top have been laid bare, and passages have been disclosed which were not previously thought of. Two of these passages, 20 and 30 feet long respectively, and between walls 8 feet high, were so concealed with rubbish that the visitors' path crossed right over them. Two large ancient entrances have also been discovered. They had been used by the native Makalangas for graves. Other architectural discoveries are a wall with dentelle pattern, a cement-lined enclosure and three wedge-shaped buttresses. The buttresses are of peculiar interest, being the first discovered in Rhodesia. Naturally, in the rubbish cleared away many "finds" have been made. These include the characteristic soapstone birds, beams and bowls. The birds are decorated in the usual fashion, and the beams and bowls show chevron and cord patterns and sometimes figures of animals. Pottery and iron tools have been discovered, but whether they are of very ancient date it is impossible to say. At any rate, they are not such as used by natives of the present day. Perhaps the most valuable discovery is a gold bangle of wirework, weighing 3½ ounces, and a beaten gold-cap, or ferrule.

Although the acropolis, with its winding walls of granite blocks, its monoliths and chambers, is the most imposing ruin, the most interesting ruin and the one in which more "finds" are likely to be

made is the temple in the plain below. A few months ago the interior of the elliptical temple was one impenetrable jungle of trees, bushes, tall grass and creepers. The monkey-rope tree and the wild vine have committed great depredations, and the last remnant of the herring-bone pattern on the wall was fast disappearing. Mr. Hall's arrival was very timely. With the help of fifteen natives he has cleared away all the undergrowth and stumps, and now for the first time an uninterrupted view of the whole structure can be obtained. The most striking object is the large conical tower about 15 feet high, which is suggestive of the old Phallic worship. This cone has suffered somewhat from the growth of trees, and is now slightly tilted. The architectural discoveries made in the temple are: four ancient drains, a double-curved rounded entrance, three sets of stone steps, and several yards of ancient cement-flooring. The cement-flooring is not original with the building. There has also been made clear a large portion of architecture which is of later date than the original building, but built on the top of an original wall. The "finds" in the temple are similar to those on the acropolis. Altogether twenty-five monoliths have been found. Among the soapstone ornaments is a section of an ancient soapstone bowl believed to be the missing portion of a large bowl lent by Mr. Rhodes to the Cape Town Museum. A collection of curious stones, foreign to the district and of odd natural shapes, was also found.

The work undertaken by Mr. Hall is purely that of clearing away the rubbish and making known the nature of the structures. No excavations are being made, so there is still plenty of scope for discovery. It is impossible to imagine that the Government mean to retain Mr. Hall only temporarily. The excellent work he has done ensures his being entrusted with further research. There are so many old ruins in South Rhodesia that it will take years to investigate the whole of them. Mr. Hall has not been unmindful of visitors, and direction-posts have been erected everywhere either to direct people to particular ruins or to indicate the particular nature of the chambers or enclosures. Zimbabwe is three hours' journey in a Cape cart from Victoria, in the south of South Rhodesia. Victoria is reached by coach now from Gwelo, which in a very short time will be connected with Bulawayo by rail. Doubtless, tourists in making the grand tour of South Africa through Kimberley and Bulawayo to the Victoria Falls will take the opportunity on their return journey to make a deviation to the unique ruins of Zimbabwe. It is to be noted that Victoria and Victoria Falls are not to be confused. They are several hundred miles apart. — *The Architect.*

IRON AND STEEL SLAG.

THE utilization of iron and steel slags is discussed in "*Mineral Resources of the United States*, 1901," now in press, United States Geological Survey, by Edwin C. Eckel, who says that, although the greater portion of the slag annually produced by iron and steel works is not available, a great deal of slag is used in the manufacture of cement and of slag brick, as a fertilizer, and in the form of mineral wool; also, to a less extent in the manufacture of paint-stock, alum and glass, and a considerable quantity is disposed of less profitably as road-material, railroad-ballast and in land reclamation.

The most important of these uses of slag is in the manufacture of structural materials, especially in the manufacture of hydraulic cements. Slag-cement is produced by pulverizing, without calcination, a mixture of granulated basic blast-furnace slag and slaked lime. This product, although really a pozzuolanic cement, is usually marketed as "Portland-cement," in spite of differing from true Portland-cement in manufacture, composition and properties. Six or eight plants are at present engaged in manufacturing slag-cement in the United States, the production for 1901 being 272,689 barrels. As slags cooled slowly are only feebly hydraulic, the slag used in the manufacture of slag-cement must be cooled as suddenly as possible. This is done by bringing the slag, as it issues from the furnace, in contact with a jet of cold water. This granulates the slag, renders it strongly hydraulic, and removes most of the sulphur. True Portland-cements can be made from mixtures of which one element is blast-furnace slag, in which case the slag is ground, intimately mixed with powdered limestone, and the mixture then calcined and reground. Two plants are engaged in the manufacture of Portland-cement from slag and limestone in the United States. In England blast-furnace slag has been somewhat largely employed as an adulterant of Portland-cement.

Slag run into moulds on issuing from the furnace furnishes blocks which have been used for paving, notably in Philadelphia. These slag-blocks are very durable, but objectionable because of their slipperiness, which, in English practice, has been overcome by the form of the mould used.

The manufacture of slag brick can hardly be considered as being more than a specialized phase of the manufacture of slag-cement. On issuing from the brick-machine the bricks are placed on racks to dry, which takes from 6 to 10 days, at the end of which time the bricks are ready for use. Slag bricks are light in color; they weigh less than clay bricks of equal size, require less mortar in laying up, and are equal to clay bricks in crushing strength.

The highly phosphatic slags produced by basic Bessemer converters are valuable fertilizers, and in Germany, especially, large quantities are annually sold under the name of Thomas silicate. These phosphate-slags are more efficient as fertilizers than the mineral phosphates. The slight development of the basic Bessemer-steel industry in the United States necessarily renders the use of these phosphatic slags of less commercial importance than in Europe. During 1901 about 1,000 tons of phosphate-slags produced in the United States were sold as fertilizer. This American material has been tested by the American Agricultural Experiment Station, which reports that slag-phosphate gave a greater total yield than did any other insoluble phosphate. The slags produced in steel-plants using the open-hearth process are less valuable as fertilizers than those produced by basic Bessemer converters, as they contain less phosphoric acid and more silica and lime than the basic Bessemer slags.

Over half the material marketed as "mineral wool" or "silicate cotton" is derived from slag, the remainder being manufactured from natural rocks of several different types. During 1901 about 3,500 tons of mineral-wool were made from slags in the United States. The most important property of slag-wool from a commercial point-of-view is that it is a very poor conductor of heat, which property renders it very valuable for all uses for which a non-conductor is desirable, as steam-pipe coverings, safe-linings, etc.

Slag has been utilized in the manufacture of paint-stock, in the preparation of alum, and, in small quantities, in the manufacture of inferior grades of glass.

About 5,000 tons of slag were sold in 1901 in the United States for use in constructing macadam highways and for railroad-ballast. Sections of roads constructed in New Jersey with slag macadam, under State supervision, have proved entirely satisfactory. Slag has been used in highway-construction to some extent near Buffalo, N. Y.; to a greater extent in Pennsylvania and Alabama, and most extensively in the counties of Baltimore, Howard and Prince George, Maryland, where, under certain conditions, it has been found highly satisfactory road-material. In several States, notably in Alabama, slag is largely used as railroad-ballast. Large quantities of slag are also used for reclaiming land and filling abandoned mine-workings.

BOOKS AND PAPERS.

MR. CROWNINSHIELD'S second book of poems[1] is quite equal in interest to the first, and shows, as it seems to us, increased smoothness and delicacy in versification. As before, he has chosen, notwithstanding its difficulties, the sonnet form for most of his work, and uses it with great skill. Perhaps the introductory sonnet, "Cor Pictoris," pleases us most, but all of them fulfil the condition essential to the sonnet, of a complete and interesting thought expressed in almost faultless verse. To one who has mastered the difficulties of the sonnet, ordinary versification is a simple matter, and Mr. Crowninshield's longer poems, some of them by no means simple in form, are models of smoothness. It is, possibly, unfortunate for modern poets that their sympathies are claimed by a multitude of interests, more or less discordant; and Mr. Crowninshield, who finds himself impelled to take poetical consideration of Browning's letters, Renaissance painting, popular actresses and imperialism, besides the usual topics of religion, landscape effect and various forms of affection, is at a certain disadvantage in regard to the unity of impression which he makes upon his readers, in comparison, let us say, with one who devotes himself exclusively to the merits of Laura or of Vittoria Colonna; but he is, at least, the more interesting in consequence.

Not the least of the attractions of the book is the charming set of illustrations. After the "poster" horrors in the way of book-ornamentation with which we have been deluged for so many years, it is truly refreshing to find drawings that really look like something,—figures drawn with some reference to the proportions of the human body, and shaded in imitation of nature, not of Beardsley, and landscapes in which the clouds are quite distinguishable from the trees, and the latter have the actual air of vegetation. To these the author adds a beautiful design for the cover, stamped simply in gold on cloth of a pretty tint, while the lightness of the paper makes the book very pleasant to hold, after the ordinary clay-loaded volume.

NOTES AND CLIPPINGS

Changes in the White House. — The north door of the White House, through which for a century visitors have passed, will hereafter be the entrance only for the President and his immediate family, domestic and official. Visitors will henceforth enter through the new eastern basement door. Where formerly was the laundry will now be the entrance-hall, and a wide staircase up which the visitor will ascend to the President's room. There will really be four White House entrances under the new order. The politicians and business callers will go to the temporary office-building on the west of the grounds; the diplomats and the like will be received at the south-front basement entrance; family and personal callers at the old front door, while the great crowds for the winter receptions will enter near the Treasury through the new terrace. The *porte cochère* there will accommodate four carriages at a time. There will be entrances also for persons on foot, but all leading to the same dressing and cloak rooms, which will be arranged so that the incoming tide will not interfere with the outgoing one. The only essential partition change of the White House first floor is that by which the state dining-room absorbs the west end of the main corridor, where the stairway used to be. The Red, Blue, and Green Rooms will remain. The East Room is much the same, except that it will be more beautiful. — *New York Times.*

Arbitration of Labor-disputes in New Zealand. — The experience of New Zealand with compulsory arbitration ought to be ascertained with exactness before this country proceeds further in its labor legislation. Mr. Frank Dillingham, our Consul at Auckland, not long ago discussed the question, but in that colorless way which characterizes the consular reports. He related that some manufacturers complained that they could not keep pace with competitors in other countries who had longer hours and cheaper labor. There can be no doubt that New Zealand is the paradise of organized labor and popular reforms. The arbitration-courts are composed of three judges, the chief of whom is appointed by the Governor and the other two by the parties in the controversy. The Court has power to enforce its mandates by all the processes incident to a Court of Record in the United States. It has power to fix minimum wages and to settle all manner of disputes. It is permitted the utmost freedom in the admission of evidence, and in technical cases often appoints a special commissioner to investigate. All industrial unions are registered, or incorporated, in order to have the right to appeal to the Court of Arbitration. Agreements with such industrial unions must be in writing. It seems to be generally conceded that New Zealand possesses such great natural resources that it could stand, for many years at least, almost any system of industrial operation. Whether the present one, with its old-age pensions, Government railroads and granaries, works well, is much disputed. A Congressman who visited there last summer gave as his private opinion that the natural resources of New Zealand received the highest compliment that could be paid to those of any country in the fact that they permitted New Zealand to hold its head up out of the ocean, in the face of the wastefulness and folly which accompanied its industrial system. Of course, the piling up of public debts, which has been going on rapidly, is preparing a problem for the future to settle. On the other hand, Mr. Henry Demarest Lloyd's books have given the American public an opposite impression of New Zealand, and between the two people can take their choice. Those who think that Tammany Hall would run the business enterprises of New York to better advantage than its great merchants, or that the Quay organization in Pennsylvania would run the coal-mines better than Mr. Baer and his associates, will naturally take Mr. Lloyd's view, and believe that his representation of New Zealand conditions is judicious. — *Lincoln in the Boston Transcript.*

German Pumice-stone Bricks. — According to a recent German report, there is in the Neuwied district along the Rhine, between Coblenz and Andernach, an extensive industry in the manufacture of bricks from volcanic sand and pumice-stone, which are found along the base of the Eifelberg. In working the deposits, the surface soil is stripped off, and the sand is piled up, to be shovelled into the mixing-bed of water and lime close at hand. The pumice comes out of the earth in pieces varying in size from grains to lumps some 4 inches across. It occurs in layers, but is frequently interrupted by small patches of more solid fragments of lava. Before moulding, the pumice is screened, larger pieces being broken to pass through a sieve with half-inch meshes. These screened pieces are then covered with a thin coating of cement, and the brick is moulded. The cement is not mixed with the pumice so as to form solid cement blocks, but by the fragments being coated first. The brick is then obtained by these coatings adhering to one another. In the manufacture of 20,000 bricks about 4½ tons of lime are required. After the mixing process, the substance is poured into iron moulds provided with bottoms of detachable boards, which, after the removal of the moulds, act as driers. When the bricks have been exposed to the air for a very short time they are ready for shipment. No modern machinery is used. A workman makes from 800 to 1,800 bricks a day. — *Exchange.*

Relics of the Lisbon Earthquake. — An interesting discovery has just been made in Lisbon which recalls the great earthquake of 1755. During some building excavations made in the Sé quarter of the city, a portico of great beauty was uncovered. Its entrance, which was closed by massive bronze doors, was thrown open, and a lofty and ornate chapel was found containing several tombs of more or less note. One of them, that of an infant, was opened and found to hold the skeleton of a female child clad in a gorgeous gold-brocade vestment, covered all over with "glories," or representations of the Holy Ghost. The tissue of the garment is still in admirable condition, and bears handling and stretching, but it is feared ere long exposure to the air will destroy the fibres and the colors. The Lisbon Archæological Society has taken possession of the relic. Further investigation proved that the remains are those of a child of Dom Pedro. Other tombs will be searched as the excavation proceeds, and rumors of additional valuable finds are already afloat. — *N. Y. Times.*

A famous Walnut Log. — The *Timber Trades' Journal* for July 12th gives the following translation of the history of a walnut log just received at Liverpool from Italy: "Referring to the log of walnut you have (sic) purchased from my brother, Anthony, last year, he got it from my deceased father, John Baptist, on April 24, 1892. My father got it on February 20, 1863, from Charles Dellanegra, who got it hereditarily from his mother, Ketty Cana, on September 28, 1840. Ketty Cana got it hereditarily from her father on April 6, 1788. The said John Baptist Cana was in possession of it before it was established in the rent-roll of this department, which was in 1768. From an old legend existing in this department it seems the said John Baptist Cana who built up the wine-press in 1747, and taking (took?) the walnut-tree from one of his properties once possessed by Count Louis Salomone in the place called Isola in the territory of this department. It is also said that there were not sufficient oxen in the region to carry the tree, which was yet green, to the place where the house was subsequently placed after having built the press. It was necessary to provide half a cow, with much bread and wine, to compensate the men who helped for the carrying of the famous log, which was considered a rarity in the country of Serrevilla. This is all I have been able to get by searching in the archives of the department and by speaking with the oldest men of the country." The account is accompanied by a lithophoto illustration of the log in question, the dimensions of which are quoted as about 26 feet long and 3 feet to 3 feet 4 inches square. — *Notes and Queries.*

The Depth of Glaciers. — For many years efforts have been made to ascertain the exact depth of glaciers by boring, but mechanical and other difficulties have hitherto frustrated the carrying out of this method of inquiry. A few days ago, however, Professors Blumke and Hess, from Bavaria, who are well known for their studies of glaciers, succeeded in boring through the Hinteries glacier, in the Otzthal Alps, at a point where the ice was found to be 153 metres deep. The machine used for boring was driven by hand, and is somewhat similar to that usually employed for experimental boring in mines, but was fitted with special arrangements for washing out fragments of ice from the bore-hole, to prevent their freezing together again. The expenses of the undertaking, which amounted to many thousands of marks, were borne by the German and Austrian Alpine Club. — *London Telegraph.*

NOTES AND CLIPPINGS. 39

A DECISION has been made by the Board of General Appraisers which is of considerable importance to persons interested in steel construction. As every one knows, the demand for structural steel in this country is so large that it is impossible to secure early delivery, and many thousands of tons of steel and iron, both crude and manufactured, are now imported, notwithstanding the heavy duties and the cost of importation. Much of the imported steel comes from Germany, and, a few weeks ago, a firm in Philadelphia had occasion to import a thousand tons of steel billets from that country, to be made up into sheets and rods. Under the Dingley tariff, the duty on steel billets, of the value of one cent a pound or less, is three-tenths of a cent per pound; but, if the value of the billets is between one cent and one and one-quarter cents, the duty is four-tenths of a cent per pound. The Dingley tariff further provides that the duty shall be calculated upon "the actual market value or wholesale price of such merchandise at the time of exportation to the United States in the principal markets of the country from which the same has been imported." A censorious person would be likely to say that this clause was, apparently, devised for the express purpose of involving importers in a lawsuit over every package of goods that they ventured to import, by substituting an indeterminate and arbitrary standard of value for the natural one of the invoice price. In the present instance, the importers of the steel billets, who paid for them eight-tenths of a cent per pound for the whole consignment of one thousand tons, thought, not unnaturally, that this fact afforded good evidence of the wholesale price of the billets at the time when they were bought, and in the market in which they purchased them, and prepared themselves to pay the duty of thirty-seven per cent. They reckoned, however, without their host. When their cargo arrived, it appeared that the custom-house officials held the view, based on evidence, the nature of which is not explained, that billets of this kind, although actually sold to the Philadelphia importers at eight-tenths of a cent a pound, were really worth one and one-thirtieth cents per pound. This valuable discovery brought with it the conclusion, perhaps not wholly unexpected, that the billets came under the second category of the Dingley law, and were, in consequence, liable to a duty of four-tenths of a cent per pound, or fifty per cent of the actual cost. In order to impress the circumstances on the minds of the people interested, a penal duty was imposed, in addition to the enhancement of the original duty, so that the importers, in place of the two thousand dollars which they had expected to contribute to the treasury of their country, were compelled to pay four thousand five hundred and fifty dollars. It should be observed that no claim was made by the Government of any undervaluation or lack of perfect integrity on the part of the importers, but the custom-house officials, under the present interpretation of the Dingley law, which assesses duties, not on what imported articles actually cost, but on what the officials in this country think they ought to have cost, simply exercised their prerogative in fixing their ideal of the proper value high enough to bring the goods under a different class. The importers, who, of course, do not charge the appraiser with anything worse than misapprehension of the facts, say that the price of one and one-thirtieth cents per pound, which the officials take to be the wholesale price of such steel in Germany, is simply the quotation for small lots, large transactions in steel billets being unusual in Germany, where all the rolling-mills and other large consumers make their own steel. Under this view, the price which the custom-house officials had heard of was really the retail price, and the wholesale price mentioned in the Dingley Act might fairly be considered to be somewhere near that at which the wholesale transaction was made. It must be acknowledged that the importers' contention is strengthened by the consideration that if the steel-maker of whom they bought their billets had known of any market in Germany in which he could have sold his goods for a cent a pound or more, he would not have been likely to sell them to the Americans for less than four-fifths of that price; and he might be presumed to know as much of the markets of his own country as the custom-house officials in New York. However this may be, the question is one which affects importations of many thousands of tons of steel already contracted for abroad, and, through them the pockets of many thousands more of American consumers of articles into which steel enters as a material, of tenants of steel buildings, and travellers over steel rails, all of whom will be compelled to contribute their portion, in the shape of increased price, or higher fares, or extra rent, to the new view of duties on the raw material.

A SERIOUS effort is to be made, at the next session of the Legislature of Massachusetts, to have an act passed under which all labor unions must be incorporated. The proposed legislation will, it is presumed, be opposed by most of the present labor leaders, but it may be hoped that the advantages of it to the workmen themselves will, before the time comes for action, be better understood than they are now. The obvious effect of incorporation of the unions will be to make them responsible bodies, capable of suing and being sued, and therefore entitled to enforce their contracts with either individuals or corporations, at the same time that they are bound by their own agreements. The importance of this, especially at the present time, when so much business is done by corporations, is so great that one of the principal trade-unions in the West has declared itself in favor of incorporation, for its own benefit. There are, however, other advantages which the members of unions gain by incorporation. While labor organizations were shadowy affairs, consisting mainly in assertions of their pretended chiefs, it was difficult to impose any responsibility on those whose membership in them could easily be denied. Now, however, the labor unions are becoming every day more definite bodies; their contracts, although still often broken, and, under present circumstances, with impunity, are more respected than ever before; and those who belong to them are less likely now than formerly to deny or repudiate their membership. This increased dignity and stability of the unions brings with it, however, a certain danger. Under certain circumstances, for example, any member could be held personally liable for all the debts of his union; or, in case of violation of the laws, an innocent member might be made legally responsible for all the damage done by other members. It is, to a great extent, to protect men from unlimited liability for the acts of their associates that the laws governing corporations have been enacted, under which the responsibility of each member of the corporation is defined and limited; and the members of unions are quite as likely as the participants in business enterprises to find this protection of value.

THE New York *Times* tells a story which has a rather familiar air. Every one knows that Fifth Avenue, in New York, from Fiftieth to Ninetieth Streets, is inhabited almost exclusively by enormously rich people, who pay from one hundred to two hundred dollars per square foot for land on which to erect palaces. Notwithstanding the general character of the district, there are no restrictions on the use to which land shall be put, and ingenious speculators are, naturally,

Entered at the Post-Office at Boston as second-class matter

exposed to the temptation to get hold of lots, and, by threatening to build objectionable structures on them, induce the neighbors to buy the lots at a good profit. Years ago, this artifice was practised on Fifth Avenue with great success, and a certain little liquor store is said to have been bought out many times, to the great advantage of its proprietor. In those days, however, thirty dollars a square foot was reckoned a good price for lots on "the Avenue," and all New York marvelled at the sale, at sixty-five dollars a foot, of a lot which would now easily bring three hundred. As the retail liquor business, even in New York, will hardly bear an investment of two or three hundred thousand dollars, at least, for a site for a small saloon, the millionaires of upper Fifth Avenue have enjoyed, for a long time, comparative immunity from alarm; but it now appears that a speculator has bought a twenty-five-foot lot in the very heart of the millionaire district, and proposes to erect upon it a fifteen-story structure, presumably an apartment-house, since an office-building in such a locality would look in vain for tenants. The *Times* is much distressed over this intrusion into a region which, whatever may be said of the architecture of some of the houses, has, in general, a pleasant air of solid and quiet wealth, but, in the absence of any restrictions, it is difficult to see how the proprietor of the lot, if he chooses to ruin himself by building an apartment-house on such costly land, can be prevented from doing so. The *Times* appeals to the example of what it calls the "paternal Government" of Paris, under which such intrusions would be impossible, and bewails the absence, in our cities, of a stricter regulation of the height and character of buildings on given streets.

IT may be said, in the first place, that it is not the "paternal Government" of Paris, the Municipal Council of which would be much amazed to hear itself described by such a name, but the universal respect of the French for artistic propriety, which has led to the regulation, with the acquiescence of the public, of the heights and character of buildings. In the case of the Rue de Rivoli, the most uniform of all Paris streets, the land was condemned and purchased by the Government, and, after the widening of the street, resold under the restrictions as to the arcading of the first floor, and the heights of string-courses and cornices, which have made it what it is; and the Rond-Point de l'Etoile, which offers the richest and most imposing of the Parisian frontages, was restricted in the same way, although even more closely; but, apart from these instances, there is, so far as we remember, no case in Paris where any restrictions are placed on building except those intended to preserve light and air, by restricting the heights of vertical walls, and the profiles of roofs. It is true that these tend to produce uniformity, for the reason that every owner is naturally disposed, for his own advantage, to build to the full height allowed by law; but the artistic instinct of the French leads them so generally to build their houses with some regard, in design, to their surroundings that the effect is to produce a sort of uniformity of politeness, if we may use such an expression, which is not legally required in Paris, any more than it is in New York or Boston, but which very happily replaces the air of elbowing self-assertion so common in street effects in both these cities. We do not say that the proprietor of a house on Fifth Avenue or Beacon Street is any more likely to be rude in his manners than the dwellers on the Avenue du Bois de Boulogne or the Parc Monceau; on the contrary, the readiness with which the proprietors of American city lots enter into agreements for reserving space around their houses, or going without stables, shows that they are as well disposed as any others in the world toward that mutual courtesy which should display itself in their dwellings, as it does in their manners; but they do not know how to give to the brick and stone of their houses the expression that they would like, and it should be the part of the architects to lead them in the matter. In New York, and still more in Boston, where there are yet unbuilt upon whole districts of what will soon be a populous and fashionable quarter, it would be easy to establish limitations of height of cornices and principal string-courses, level of first floor, and, possibly, material of fronts, which would add greatly to the beauty of the blocks of new houses. To avoid monotony, the restrictions might differ, to a certain extent, in the various blocks, and care should be taken not to make such limitations as would shut out an interesting variety, even in the same block. If the question could be at first maturely studied by the architects, there would be little difficulty in persuading owners to accede to restrictions which would benefit them as much as their neighbors, and the example of a single block, built without the convulsed sky-line, the leaping up and down of front doors, and the ham-sandwich effect of alternating vertical slices of red brick, white marble, brownstone, yellow brick and limestone, would do much to educate the public to a better conception of civic architecture.

IT is to be regretted that certain journalists have created a little sensation by the discovery, which they profess to have made, that the acceptance of gifts of libraries, and other public benefits, from the munificence of private individuals, tends to pauperize communities. They call to mind a time when, as they allege, public improvements were made by voluntary contributions of the citizens, or by taxation, and draw a sad picture of the spread of municipal mendicancy. It would be interesting to the student of history to know at what time, and in what place, any library has ever been erected, or any park laid out, by the voluntary contribution of any considerable number of citizens. So far as we can judge from the experience of the world, for at least two thousand years, libraries, museums, universities, hospitals, parks and other important public benefits have always been conferred upon the community by some rich citizen, or, occasionally, by the coöperation of a few rich citizens, or have been paid for with money raised by taxation. With churches the case is different, and, although there are many examples of ecclesiastical structures erected at the expense of a single individual, the great majority have always been paid for by the contributions of a large number of people; while statues and monuments are commonly erected by the aid of a long subscription list; but it is safe to say that if the world had depended on taxation, or on voluntary contribution from a large number of citizens, for universities, hospitals and libraries it would possess very few of them. We are as much opposed as any one could be to the pauperizing of individuals by unwise charity, but it is a maxim of social science that a child is not pauperized, but, on the contrary, encouraged and strengthened for his future duties, by kindness, and the same rule holds good, to a great extent, of communities, which gladly and gratefully receive from individuals benefits which they are unable to provide for themselves, or which, in many cases, they do not understand the value of until they receive them. One writer on the subject mentions the case of a village which refused the gift of a library, because the citizens thought that the acceptance of the gift would "discourage self-reliance." This is commendable enough, but it may be fairly offset by the example of more than one small town, which has refused the gift of a library, on the ground that the citizens would have to hire a librarian, and buy coal to keep the building warm in winter, and that they did not wish to involve themselves in these expenses. A good library would do more, perhaps, than anything else to raise a community to a higher appreciation than this of the benefit of books; but it may be imagined that it would be a long time before such a village as this would change its disposition so far as to appropriate money to provide the library itself, as well as the cost of maintenance. In fact, the necessity for providing maintenance for the libraries and hospitals given or bequeathed to a municipality involves a sacrifice which, in itself, removes the pauperizing element from the gift. A boy who receives a present of a chest of tools, which he could not pay for out of his own small store of pocket-money, is happy in using the tools to make things for his friends, and gains in all good and manly qualities by doing so; and, in the same way, a community, through the sacrifices which it has to make in utilizing the gifts of benefactors, becomes more intelligent, more efficient, and less selfish. Americans have a reputation, of which they may well be proud, of being the most public-spirited people in the world; and it is a pity to do anything to discourage the habit of using one's superfluity for the advantage of other people which has done more than anything else to raise the world from barbarism to civilization, and which has still an ever-widening field before it.

THE Italian Government has done a wise thing in purchasing the Villa Borghese, just outside the walls of Rome, for conversion into a public park. Rome is now a great modern city, full of a poor and hardworking population, which has little opportunity for breathing fresh air, and the Borghese gardens, which are on high land, overlooking the city, will supply a ready-made park of the best character. The pictures and sculptures of the Villa Borghese were purchased by the Italian Government some time ago, and removed to a place of safety, and it may be hoped that the acquisition of the gardens will prove profitable to the Government, as well as to the poor people whom it has sought to benefit, through the increase in taxable value of property surrounding them.

RELATIVE COMPRESSIVE STRENGTH OF GRAVEL AND BROKEN-STONE CONCRETES.

THE tests outlined below were made for Messrs. Woodbury & Leighton, of Boston, in 1896. Although the writer had no connection with them professionally, the results obtained show so interesting a comparison between the compressive strength of concrete made with gravel and the strength of similarly proportioned concrete made with broken stone as to warrant the publication of a condensed summary.

The result of the tests which were made at the Watertown Arsenal shows that under the conditions described in full farther on concrete cubes 12 inches on a side, mixed in proportions of one part loose cement to 3 parts sand to 5 parts broken stone, are, after setting one or two months, 47 per cent stronger than similar cubes of concrete made with the same proportions of mixture, except that screened bank-gravel is substituted for the broken stone.

The experiments recorded are of special value on account of the lack of data bearing upon the subject in architectural and engineering literature. Formerly it was the general opinion that concrete made with gravel was stronger than similar concrete made with broken stone. Many architects and engineers still give an optional choice of these materials in their specifications, although the records of tests made are nearly all in favor of broken stone.

The best published results of tests bearing upon this subject are quoted in Baker's "*Masonry Construction.*" Tests made in Washington, D. C., by the Engineer Department are there referred to, and the conclusion is drawn from them that broken stone concrete is undoubtedly stronger than gravel-concrete, but that as the age of the concretes increases the difference between them becomes less marked. Tests made in France with coarse materials also favor the broken stone. Various proportions of materials were experimented upon there. With the proportions similar to those of the Woodbury & Leighton tests the percentage in the French tests in favor of broken stone is considerably smaller than in the former, being about 26 per cent. This difference is probably due to the difference in the materials used. As the proportion of cement in the concrete increases the relative difference in strength between broken-stone and gravel concrete decreases.

We will turn now to the tests which it is the object of this article to describe. The experiments were made by the contractors, Messrs. Woodbury & Leighton, to determine the best materials to use in the foundations of the new Houghton & Dutton Building on Pemberton Square, Boston. Twenty-six cubes of concrete measuring 12 inches on each edge were made, and after setting thirty or sixty days, were tested by the United States Ordnance Department at the Watertown Arsenal, Watertown, Mass. Sixteen of these tests were made to compare the strengths of concretes made with different proportions of materials, but the results from these will not be touched upon in this article. The quality of all Portland-cements has been gradually improving, even since so recent a date as 1896, and therefore the relative rather than the actual results of the tests are of value at the present time.

Three brands of Portland-cement were used, two of these being selected as the best European cements on the market and the third as the best American Portland-cement. The gravel used for the gravel-concrete was of rather small size. The largest stones did not run over 2 inches in diameter, and the average size was considerably less than this. The gravel was obtained from the excavation for the building to be erected, and it was screened over a quarter-inch-mesh screen to remove the sand. It was clean, containing practically no clay or loam. The sand from both the gravel and the broken-stone concrete was the same, consisting of ordinary clean coarse bank-sand, which was purchased by the contractors and hauled to the site of the building. The broken stone was of uniform size, averaging but little over one inch in dimensions, the dust and coarser stone having been screened out.

For measuring the materials, cubical boxes exactly 12 inches on each edge were used. The cement was measured in these boxes, loose. This fact must specially be noticed because the resulting concrete was less rich than it would have been if the cement had been measured by the packed barrel, as is customary on a great deal of construction work. The gravel and the stone were measured in the same cubic-foot boxes, and then spread out on a platform. The cement and sand, after measuring, were mixed dry and spread on the gravel, the water being added as the entire mass was mixed. One cubic foot of water was used to each cubic foot of cement. This gave a mixture which was fairly wet, quaking slightly when rammed. The proportions of the mixtures in each of the cases which we are now considering were one part loose Portland-cement, 3 parts sand, and 5 parts broken stone or gravel.

A cubic foot of loose cement as it was measured in the experiments is equivalent to .78 cubic feet packed cement as measured in a barrel direct from the manufacturers. This ratio was determined from calculations made and published by the writer based on tests made for the Boston Transit Commission in 1896.[2] If the proportions, therefore, in the Woodbury & Leighton tests had been expressed in terms of packed cement, we should have had one part packed cement to $3\frac{3}{4}$ parts sand to $6\frac{1}{4}$ parts broken stone or gravel.

After setting, the compressed surfaces of the cubes were faced with plaster-of-Paris. A part of the cubes were allowed to set thirty days, and a part sixty days. They were then tested by direct compression in the United States Testing-machine having a capacity of 800,000 pounds.

The results of the tests on the ten cubes used for a comparison of gravel and broken stone are tabulated in full below. The dimensions given are of interest chiefly in showing the accuracy with which the tests are conducted by the U. S. Army Ordnance Department. The figures are copied directly from the Department reports, with the insertion of the column of "Ratio of Strength of Broken-stone to Gravel Concrete," and the "Remarks." The "Number of Test" is simply a mark given by the Arsenal and has no reference to the quality of the cube. It will be noticed that the ratios are figured for each pair of tests, since the gravel and stone concretes are tabulated alternately, the two tests in each pair representing similar conditions throughout. The fact that the tests of foreign cements, which are designated as A and B, ran higher than those of American cement, called C, is of no special value at the present time, because, as has already been stated, the qualities of cements are being continually improved. As a matter of fact, also, subsequent tests made by Woodbury & Leighton at the Watertown Arsenal show that first-class American Portland-cement is equivalent in crushing strength, when made into concrete, to first-class foreign cement.

The ratio of strength of broken-stone concrete to gravel concrete has a final average in the table of 1.47. This means that under conditions similar to those in these experiments — that is, with mixture of one part loose cement to 3 parts sand to 3 parts stone or gravel — broken-stone concrete, after setting thirty or sixty days, will be 47 per cent stronger than concrete in similar proportions made with gravel for the aggregate. In making use of this result stress must be laid upon the fact that the tests were made under practical rather than laboratory conditions. The results from such tests are often more valuable than those made in a laboratory because the conditions are similar to those met with in actual building construction. The gravel was unwashed. If it had been made absolutely clean it is probable that the gravel-concretes would have shown greater strength and the ratio of strength of the two classes of concrete would have been smaller. As a matter of fact, however, the gravel used in building foundations, if it is fairly clean, unfortunately is apt to be washed so slightly that minute particles of dust and dirt remain on the stones. Hence, the tests in this respect correspond to practical conditions. The resultant ratio of the strength of broken-stone concrete to that of gravel-concrete obtained by these tests cannot be taken as exactly applicable to a comparison of concretes mixed with a larger or smaller proportion of cement. It is reasonable to assume

RELATIVE COMPRESSIVE STRENGTH OF GRAVEL AND BROKEN-STONE CONCRETES.

Note. — Proportions of all cubes were one part *loose* Portland-cement, 3 parts sand, 5 parts gravel or stone.

[2] See *Engineering News*, Vol. XLIV, p. 229.

that the relative difference in strength between broken-stone and gravel concretes will decrease as the quantity of cement used to the cubic yard decreases; that is, in a rich concrete it makes less difference whether broken stone or gravel is selected. This conclusion is borne out by the French tests mentioned above. In these the percentage of difference varies from 16 per cent to 30 per cent.

For practical purposes we may assume that the percentage of increased compressive strength of broken-stone concrete over gravel concrete runs approximately as is given in the following table. This table is based chiefly upon the French tests and the Woodbury & Leighton tests and applies to concrete which has set not more than a few weeks. In concrete which has set a longer time the ratios would probably be less.

Proportions of Concrete.			Ratio of Strength of Broken-stone to Gravel Concrete.
Parts Cement.	Parts Sand.	Parts Gravel or Stone.	
1	2	3	1.16 to 1.28
1	2	5	1.20 to 1.35
1	3	7	1.26 to 1.46
1	4	10	1.30 to 1.53

The fact that concrete made with broken stone is stronger than concrete made with gravel and having the same proportions of materials, does not necessarily prove that the use of gravel in concrete should be discontinued, nor that good specifications should always require broken stone. It does prove, however, that a very careful study of the matter should be made in any important undertaking. The economic side of the question will often determine that gravel is preferable, even although the strength of the resulting concrete is less. If great strength is required, it may be often cheaper to increase the proportion of cement in the mixture and use a gravel aggregate rather than to use the smaller quantity of cement with broken stone. On the other hand, it should be borne in mind that since broken-stone concrete is in general stronger than gravel concrete, a slightly higher cost per cubic yard of broken stone may often be more than balanced by the use of a less quantity of cement per cubic yard of concrete.

In deciding whether gravel or broken stone is the most economical, the fact should be noticed that since broken stone has in general a larger proportion of voids than gravel, a larger quantity of it as well as of cement and sand per cubic yard of concrete will be required than if gravel is used. This fact may not be obvious at first thought, and it is often disregarded in very careful estimates. A simple way of explaining it is that since a given quantity of broken stone has more voids, or spaces, than the same quantity of gravel, a larger proportion of mortar will be required to fill these voids, or spaces. If the proportions of the broken stone or gravel, the sand and the cement are definitely fixed with relation to each other, the mixture of the materials which have the greatest amount of solid matter will produce the largest quantity of concrete. As such small attention has been paid to this fact it may be worth while to illustrate it more fully with an example. We may assume for comparison that the broken stone has 50 per cent voids and that the gravel has 33 per cent voids. A mixture of 5 cubic feet of loose broken stone with, say, 3.5 cubic feet of mortar will give with perfect mixture 50 per cent of 5 cubic feet plus 3.5 cubic feet, or 6 cubic feet of concrete. On the other hand, 5 cubic feet of gravel mixed with 3.5 cubic feet of mortar will give 67 per cent of 5 cubic feet plus 3.5 cubic feet, or 6.8 cubic feet of concrete. In other words, in this assumed case the gravel materials will make over 10 per cent more concrete than the broken-stone materials, and conversely, approximately 10 per cent less in quantity of the gravel materials than of the broken-stone materials will be required to make a definite quantity of concrete.

For a small mass of concrete it may be cheaper to select materials and proportion them so richly that the result will be beyond question rather than to go to the expense of making tests. On large work, however, it is worth while, both on the score of economy and strength, to make special tests of the materials which are available in the locality where the job is situated. SANFORD E. THOMPSON.

CORROSION OF STEEL FRAMES OF BUILDINGS.[1]

THE constantly increasing use of steel as a structural member in modern buildings has led to many questions as to the permanency of the steel as sometimes used for this purpose. The examination of buildings 10 to 15 years old, when, during alterations, the steel framework has been exposed to view, reveals all stages and conditions of disintegration of the steel. So great has been the corrosion, even in this short time, in some cases, that a note of alarm has been sounded by some engineers most familiar with the subject. The use of steel beams and posts is of so recent date that no very exact deduction can be drawn as to the exact time required for a very serious or destructive loss of steel through corrosion; but surely, when a steel plate $\frac{1}{2}$ inch in thickness loses more than $\frac{1}{8}$ inch in 5 years, there arises a question as to the ability of the structure to last more than 25 years.

Some of the factors in the matter of corrosion of the steel we know; others we do not know, and cannot until after a lapse of some years.

There can be no question that moisture and carbon-dioxide are the active agents in causing much of the rusting of the steel. To what an extent the two are relatively responsible and in what measure they need renewal, to keep up the process, is uncertain. It has been held that the formation of a coat of rust upon the surface of steel was the beginning of a progressive action whereby the rust, or iron-oxide, acted as a continuous carrier of oxygen to the steel beneath. This process seems to require only moisture and atmospheric air containing carbon-dioxide to start it, but as to the depth of penetration of the process I know of no assignable maximum in any given time. It is extremely probable that in a comparatively dry place the process is extremely slow.

There can, of course, be no question as to the ease of access to the steel, in many cases, of both moisture and carbon-dioxide. When steel is bedded in the wall of the building, as is almost always the case, the changes in temperature from time to time, as well as the more or less constant difference in temperature between the two faces of the wall, tends to cause a condensation of moisture in the wall at different points. Further, the necessary carbon-dioxide is most plentiful in the large cities, while the steel-frame is most common.

When the walls of the building are of brick or stone, moisture and carbon-dioxide may usually enter at the joints and, to a greater or less extent, through the body of the stone or brick. Few stones are, however, porous to such an extent as to allow an appreciable penetration. Terra-cotta tile is of itself porous, and the existence of air-passages tends to increase the condensation of moisture and absorption by the terra-cotta and possible contact with the steel. Concrete, made of Portland-cement with sand and either cinders or stone, would seem to offer more protection to the steel than any of the materials just mentioned; yet, we hear from time to time of the loss, by corrosion, of steel bedded in concrete.

A study of the action of Portland-cement concrete on steel was begun under my direction by Mr. P. C. Pearson in December, 1901, and it is my purpose to report upon this and some later observations as a preliminary to more work of the same nature now under way.

It has been held by several engineers that the mere alkaline nature of Portland-cement was a sufficient guaranty of its protecting steel from rusting. There is, of course, good chemical reasoning for this, the familiar use of strong alkaline solution in boilers to prevent the formation of scale being based upon the same principle. This would seem to settle the matter once and for all, were it not a fact that steel bedded in concrete has corroded very rapidly, while other steel in a different concrete of the same kind of cement stands without change for 10 years or more.

The investigation was started not to find out that steel could not be protected by concrete or that it could be, for on that point we were sure, to start with, but we have tried to find a reason for occasional failure and to suggest a remedy.

An examination of several cases where expanded-metal had been embedded in concrete showed plainly that wherever the steel was exposed through cracking rusting began, even though the cracks were very fine. It would seem that the alkaline nature of the cement would be sufficient to prevent corrosive action occurring within a few hundredths of an inch on the moist surface of the steel, but such is not always the case.

To study the matter systematically, two brands of American Portland-cement (*Alpha* and *Lehigh*) were selected; two kinds of cinders, one from the Sugar Refinery, the other from the Boston and Albany locomotives; a sharp, clean beach-sand; and a hard, clean broken stone, the larger part being fragments of flint and trap-rock. Concretes were made up in bricks about 3″ x 3″ x 8″, with the steel specimens near the centre.

The following mixtures were tried at first; others will be reported on later: Neat cement; cement, one part to 3 of sand; one part of cement and 5 parts of broken stone; and one part of cement to 7 parts of cinders. All briquettes were made in duplicate with both cements. There were later made up briquettes of one part of cement to 2 parts of sand and 5 parts of cinders, and of one part cement to 2 of sand and 5 of crushed stone. The table below gives a summary of the mixtures: —

Alpha Cement.	Lehigh Cement.	Sand.	Stone.	Cinders.
1	0	0	0	0
0	1	0	0	0
1	0	3	0	0
0	1	3	0	0
1	0	0	5	0
0	1	0	5	0
1	0	2	5	0
0	1	2	5	0
1	0	0	0	7
0	1	0	0	7
1	0	2	0	7
0	1	2	0	7

It was hoped to vary the density, the porosity and the nature of the contact with the steel, as well as the chemical composition of the concretes. The cements were tested chemically and physically and found good. The cinders, when washed down with a hose stream and dried, tested distinctly alkaline, and analysis revealed very small amounts of sulphur. The stone and sand were thoroughly washed and clean. The ingredients were mixed dry in every case and, when wet, thoroughly mixed and tamped until wet on top.

[1] Report No. IV of the Insurance Engineering Experiment Station, Boston, Mass.

The cleaning of the steel was the most troublesome problem met with. It was necessary to scour the pieces, then pickle in hot dilute sulphuric acid, and finally dip into hot milk of lime. When cold, the lime was removed with a wire brush. This left the steel clean and bright, ready to be put into the test-bricks.

The specimens used were a mild-steel rod 6 inches long and $\frac{1}{4}$ inch in diameter, a piece of soft sheet-steel $6'' \times 1'' \times \frac{1}{32}''$ and a strip of expanded-metal $6'' \times 1''$, all three pieces being put in each brick. Since time would not permit of our exposing these specimens to natural conditions, we enclosed them in several large tin boxes, sealed tightly, and subjected one quarter of them to an atmosphere of steam, air and carbon-dioxide, and second quarter to air and steam, a third to air and carbon-dioxide, and a fourth stood upon the table of the room, with no special care as to their temperature or dryness. Of the entire number, about one-half were set in water for one day, the rest for 7 days, before sealing up.

At the end of 3 weeks the briquettes were carefully cut open and the steel examined and compared with specimens which had lain unprotected in each of the tin boxes.

Those specimens which were mixed of neat cement can be dismissed without discussion, for the protection was perfect. The steel was as bright as when put in.

The unprotected pieces were found to consist of rather more rust than steel. The steel was wrapped about pieces of uralite, to serve as a means of identifying it by number, the stamped numbers being nearly obliterated by the rust.

Of the remaining specimens, hardly one had escaped serious corrosion. The location of the rust-spot was invariably coincident with either a void in the concrete or a badly rusted cinder.

In the more porous mixtures, the steel was spotted with alternate bright and badly rusted areas, each clearly defined. In both the solid and the porous cinder-concretes, many rust-spots were found, except where the concrete had been mixed very wet, in which case the watery cement had coated nearly the whole of the steel, like a paint, and protected it.

Some briquettes made later of finely-ground cinders and cement, in varying proportions, when exposed to moisture and carbonic-acid, showed how effectually the presence of cement prevented rusting, even in a highly porous mass — one of cement to 10 of cinder, provided there were no cracks or crevices or distinct voids.

From the examination of these several hundred briquettes we were able to draw several conclusions: —

First. — Neat Portland-cement, even in thin layers, is an effective preventive of rusting.

Second. — Concretes, to be effective in preventing rust, must be dense and without voids or cracks. They should be mixed quite wet where applied to the metal.

Third. — The corrosion found in cinder-concrete is mainly due to the iron-oxide, or rust, in the cinders and *not* to the sulphur.

Fourth. — Cinder-concrete, if free from voids and well rammed when wet, is about as effective as stone-concrete in protecting steel.

Fifth. — It is of the utmost importance that the steel be clean when bedded in concrete. Scraping, pickling, a sand-blast and lime should be used, if necessary, to have the metal clean when built into a wall.

In the matter of paints for steel, there is a wide difference of opinion. I cannot believe that any of the paints of which I have any knowledge can compare with a wash or painting with cement. Moreover, if paint does disintegrate, it leaves a thin void next the steel, the worst possible condition. I examined some steel Z-bars not long ago, which were exposed in process of altering a building 5 years old. It was clear that the steel was rusty when painted and that moisture had penetrated through the paint, caused the rust to increase and split off the paint. This was a case where the steel was built into the brickwork with no attempt at any protection other than the paint.

It is, in my opinion, perfectly clear that the coating of all steelwork with cement before applying the concrete or tile or brick, as the case may be, is an absolute essential, if the formation of rust and consequent weakening of the steel is to be prevented. The thickness of the cement-layer need not be great, but it should be a continuous coating, without cracks. The steel should be perfectly clean; but if, as is often the case, the choice is between paint and rust which accumulates during construction, the paint is to be preferred.

Mr. Pearson suggested the use of Portland-cement in protecting the under side of railroad-bridges against rust and the blasting action of the gases and cinders from locomotives. I think this merits a careful trial.

It is intended to take up the study of paints as a protection for steel, and to study, as well, the action of corrosion with long lapses of time in the walls and buildings of the Experiment Station now about to be erected. The first fire-testing work will also be upon the tile, brick and concrete protection of steel from fire. Next we propose to study the effectiveness of the many kinds of "finish" for buildings. A small two-story house of refractory material, into which the finish to be tested can be built, is needed for this work, and already several materials are waiting to be tested. The kiln for testing floor-spans, beams and posts is to be about $15'' \times 20''$, and it will be heated by a battery of oil-burners well above the melting-point of cast-iron.

CHARLES L. NORTON.

LABOR-TRUSTS THE WORST.

ONE of the sanest and most logical presentations of the really important rights and principles involved in such labor disturbances as the anthracite-coal strike that the recent popular newspaper discussion has brought to light is that made by Mr. Robert S. Minot in the following communication addressed to the Boston *Transcript*: —

"TO THE EDITOR OF THE TRANSCRIPT: —

"The present anthracite-coal strike is prima facie the fault of the miners, because they voted to strike and struck, and the burden of proof is on them to show the contrary. A corresponding lockout by the operators would be prima facie their fault, but such lockouts do not occur and would not be tolerated if they did. There is no more reason for tolerating such a strike. A strike is an act of selfishness and brutality to the employer, to the striker's own wife and children, to the non-union worker, who works at the peril of his life, and to the public who suffers, particularly the poor, of the striker's own class.

"Whatever the sins of the operators, they do not often lockout, nor kill nor wound, except in lawful defence, nor starve their own families or others. They do not paralyze industry by mob-rule and criminal violence. The worst sin they are usually charged with is excessive prices, and that charge has never been proved, the retail dealers being now the worst offenders.

"The great trust-issue to-day is the labor-trusts. The others are comparatively unimportant and can be dealt with later. At most they make prices high, but the labor-trusts arrogate to themselves the right to paralyze production to the extent of their power. They have attempted to paralyze railroad-transportation, notably in 1877; street-railroad transportation, as in Brooklyn, Cleveland and Boston; building-operations, as in New York and Chicago; and now the production of coal, which strike means, if much prolonged, paralysis of all industry, transportation, education, and even destruction of life.

"There is always about the same routine. The vote to strike and the strike with little or no notice, selfish, ugly, brutal and destructive; the abuse and killing and wounding of non-union men; the destruction of employers' property and distress of the consumer and the public. If the labor-trusts had unlimited power what limit would there be to these results? They dread the law when properly enforced, and public opinion when it is not poisoned with false sentiment, and the exhaustion of their own means. Thus their power ends and so their strikes. They talk of equal rights and liberty, but deny them without justice or mercy to the 'scab,' whose life they take because he tries to earn his daily bread for himself, and his wife and little ones, for something less than union wages.

"If the 'scab' has no right to work for wages satisfactory to him, there certainly exists no right for union men to strike, but granting that there is the individual right to work, or to stop working, should not, must not, strikes such as this coal-strike, which if much prolonged may perhaps mean anarchy paralleled only by such historical instances of mob-rule as the French Revolution, be made by law criminal conspiracies, to be justly punished?

"The manual laborers are forming themselves into a striking-class distinct from the rest of the community. Misled by bad leaders, outvoted by their more radical members, they are ever prone in time of strikes to lawlessness and crime. What a terrible inheritance for their children!

"The working-classes are, like all other classes, made up of good, bad and indifferent individuals. It is only when the bad are in control that a whole class goes wrong. Their only salvation lies first in submission and obedience to the law of the land, and in true loyalty to their own families, to their contracts with their employers and to the public which depends on their continuous labor. The American public is over-patient and long-suffering, but once it sees clear, and is aroused and antagonized, no enemy is safe.

"No just or humane man or woman but knows that employers are too often selfish, hard and unjust, and wishes justice and consideration, humanity and kindness for every deserving workingman or woman, but every reasonable man sees that strikes are essentially civil war and rebellion on a minor scale, and when they break out in lawlessness, the first step, even for the striker's sake, is to restore law and order. Then there should be State boards of arbitration and conciliation, or courts of justice, to which all such disputes could be referred, like all other disputes. Why should the manual laborers not settle their disputes as the rest of us do? Public opinion will do the rest.

"There are deep lessons to be learned from this strike.

"*First.* — That the public interests vastly outweigh those of the operators or miners.

"*Second.* — That selfishness, antagonism, injustice and brutality are not practical qualities in the higher evolution of mankind.

"*Third.* — That the war-spirit, which Theodore Roosevelt, our President, has done somewhat to evoke and promote, is capable, in the midst of peace and unparalleled prosperity, of raising a hell too strenuous even for him, such as he has far more desire than power to quell.

"*Fourth.* — Universal suffrage is in peril in the North. It no longer exists in the South, the Negro having lost the ballot with scarcely a murmur of protest in the North, which fought the War of the Rebellion but forty years ago to give that ballot with freedom. It is just and necessary that habitual criminals should be disfranchised. A

period of disfranchisement would be a just punishment for any serious lawbreaking. Should such disfranchisement laws be enacted (and none but criminals or would-be criminals could well oppose them), those classes who were most lawless would suffer this penalty the most, and thus the element of 'politics' would gradually be somewhat eliminated in dealing with lawlessness of all kinds. To plunge lawlessness deeper into politics would be to leap out of the frying-pan into the fire. ROBERT S. MINOT.

"BOSTON, October 9, 1902."

FERRO-CONCRETE.

AT a meeting of the Society of Engineers held at the Royal United Service Institution, Whitehall, on Monday evening, a paper was read on "The Hennebique System of Ferro-Concrete Construction," by Mr. Augustus de Rohan Galbraith. The author stated that the originator of the principle was M. Joseph Monier, a Frenchman, and that it was first applied to the manufacture of slabs and pipes in ferro-cement. He then described the ferro-concrete system invented by M. Hennebique, a French engineer, which system has been widely introduced in practice in France, including the construction of a bridge of three arches at Chatellerault, 26 feet 3 inches wide, and having a centre-span of 172 feet and two side-spans of 135 feet each. This system is also being adopted in this country in various engineering-works, notably in connection with the Old Quay widening, and new dock-works of the London and Southwestern Railway Company at Southampton. The Hennebique principle consists in embedding in concrete straight and cranked iron or steel tension-bars and stirrups, to take the shearing-stresses, together with distance-pieces, the system being applicable to, and employed in, entire buildings from foundation to roof, inclusive. The piles used at Southampton are built up in vertical moulds, in which are placed long steel rods, which give the required strength. These are laced together with wire stirrups, and Portland-cement concrete of the best quality is filled into the moulds and rammed round the steel. After a month the pile is taken out of its mould and driven in position, much in the same way as timber piles are. The ram is exceptionally heavy, generally 30 cwt. The head of the pile is protected from injury by covering it with a hemlet, or iron case, filled with sawdust; a timber dolly is always used. The author then pointed out the care required in the selection and preparation of the materials, explaining that the usual proportions of the concrete were five to one, and giving the preference to Siemens-Martin steel over Bessemer steel, owing to the purer and more uniformly good quality of the former. He then dealt with the application of the system in general construction, giving the results of some tests of Hennebique beams with and without stirrups, which proved the superior strength of the former. He then stated that the results of experiments by Professors Bauschinger and Ritter showed that the adherence of iron to concrete was about 570 pounds per square inch. The coefficient of expansion and contraction of steel and concrete was found by M. Durand Claye to be identical up to the fifth decimal, giving the breaking strain of concrete as between 3,000 pounds and 4,000 pounds per square inch. The advantages of the system as regards fire-resistance were then illustrated by the light of some severe fire-tests carried out at Ghent, together with the results of a fire which occurred at a spinning-mill at St. Etienne, Belgium, which proved that ferro-concrete structures were perfectly fireproof. The author then gave the following examples of the cost of the Hennebique system as carried out in different structures: The Chatellerault Bridge, £18 12*s.* per lineal foot; a grain-warehouse at Plymouth, 4½*d.* per cubic foot of space; a flour-mill at Swansea, 4¼*d.* per cubic foot; grain-silos at Swansea, 6½*d.* per cubic foot, and some coal-hoppers at Portsmouth, 7¼*d.* per cubic foot. — *Building News.*

THE STRENGTH OF FERRO, OR ARMORED, CONCRETE.

A SERIES of valuable experiments has recently been carried out by a commission appointed by the Ministre des Travaux Publiques, with a view to ascertaining the precise *rôle* which the metal plays in armored-concrete construction. The results, as described by M. Considere in a communication to the Paris Académie des Sciences, are particularly interesting. The specimens used by the commission in the tests were generally in the form of bars 2 metres (2.187 yards) long, and had a cross-section 10 centimetres (3.9 inches) square. Each of these concrete bars was reënforced at the corners by four steel rods, having a total section of 113 square millimetres (.176 square inches). The concrete employed was made by mixing 300 kilogrammes (660.7 pounds) of Portland-cement with .800 cubic metres (28.25 cubic feet) of gravel, passing a 25-millimetre (.98 inch) screen, and .400 cubic metre (14.12 cubic feet) of sand, passing a 5-millimetre (.19 inch) screen. It was found that, in setting, the contraction of the concrete gave rise to an initial compression in the steel reënforcement amounting to 2,923.76 kilogrammes (2.87 tons) per square inch of the metal. The corresponding tensile forces simultaneously called forth on the concrete amounted to 33.57 kilogrammes (73.9 pounds) per square inch. Tested in tension it was found that the specimens stretched rapidly until the stress on the concrete was practically equal to the ordinary tensile strength of this material. From this point the tested bar stretched much less rapidly, and throughout this period the tensile stresses in the concrete remained constant, the whole increase of load being taken by the iron bar. It follows, therefore, that during this period the elastic modulus of the concrete was zero. In one case the test-bar was subjected to a load of 2,060 kilogrammes (2.2 tons), equivalent to a stress of 132.45 kilogrammes (291.7 pounds) per square inch of cross-section, under which the total expansion of the specimen was 6 millimetres (.024 inch). The reënforcing rods were then cut out, and the cross-shaped bar left was tested in cross-breaking, and in spite of being somewhat injured in the cutting out of the reënforcing bars, only failed under a calculated stress of 58 kilogrammes (127.7 pounds) per square inch. Summing up, M. Considere states that armored concrete submitted to tension acts in exactly the same manner as ordinary concrete, so long as the tensile stress does not exceed the usual breaking stress of ordinary concrete. Under higher stresses it will support without breaking extensions which, in the case of specimens hardened under water, have been as great as one five-hundredth of the total length; and, in the case of air-hardened concrete, have ranged between one eight-hundred-and-fiftieth, and one two-thousandth of the total length. When the ferro-concrete is stretched beyond the usual elastic range of ordinary concrete, the tensile stress on the concrete remains constant up to the ultimate breaking point, the whole of the additional load being taken up by the metal. When subjected to repeated tensile stresses, however, the fraction of the load carried by the metal tends to augment and that of the concrete to fall, until ultimately the working-stress on the concrete is only 70 per cent of its original value. If, finally, after a series of loadings and unloadings, the maximum load is raised 30 per cent, the concrete again exerts a tensile resistance equal to its primitive value. — *Stone Trades Journal.*

BOOKS AND PAPERS.

PROBABLY most people, if asked whether another book upon Rembrandt were necessary, would reply in the negative; and yet, in spite of numerous volumes, small and large, this little three-and-sixpenny book is not only right welcome, but it can be highly commended — as examiners say.[1] It is exactly what it pretends to be — a critical essay; not a mere bagful of facts strung together for the semi-ignorant. It supposes a certain amount of knowledge upon the subject, and an intimate acquaintance with the painter and his works. Moreover, it deals more with Rembrandt's drawings and engravings than with his pictures; but, in the author's own words, most of the details in the book "are drawn from Emile Michel's very full work on the subject." And yet the book is not only pleasant reading, but it fills up, in a small space, a certain void.

There are no reproductions of Rembrandt's pictures, because, says M. Bréal, bringing them down to the size of the book would be a betrayal. So the author determined to reproduce the painter's drawings and engravings from the collections in the British Museum, his object being to make people "love Rembrandt, not to judge him. If we could help to get Rembrandt's work looked at in some degree as Rembrandt knew how to look at a shell, a tree, an old woman or the veiled line of the horizon, our end will have been attained."

The author is hard upon critics and experts who condemn an etching as not Rembrandt's because it is clumsy or in bad taste. As he truly says, "In him there is no formula. He renews himself in every work and has no other care than that of rendering visible what he feels to be. He pursues this aim by any and every method, and when he touches it he stops; this is the explanation of those 'changes of manner' which we shall often remark in the same painting or the same etching."

And the people who "interpret" painters are also criticised, the folks who discover "philosophic intentions at which the artist, not having supposed himself so clever, would have a right to stand amazed" — systems of thought of which the painter was quite innocent — these people discourse eloquently upon the coarseness of some of the subjects of his pictures as being quite "unworthy of Rembrandt."

Whether M. Bréal is right in his defence of the painter's nude studies, or rather the Dutch *fraus* who sat for him, is questionable. Certainly, one cannot defend an ugly *ensemble* as one can an ugly face, which loses its ugliness by its expression, whereas the "altogether" has to depend upon line and color; and there is no reason why, if we condemn nudities which are only unclothed *hausfrauen*, we should be supposed to admire Greuze's *double entendres* and harmful imbecilities. However, the chapter upon this subject (IV) is well worth reading; much of it is perfectly true, and all the argument is well reasoned and worked out.

The translation is good and reflects credit upon Miss Clementina Black.

ARCHÆOLOGISTS interested in London should read "*Mediæval London*," [2] an excellently illustrated account of the city and its buildings. Many of the reproductions are from some drawings in the British Museum done by J. Wykeham Archer in 1841.

[1] "*Rembrandt: a Critical Essay.*" By Auguste Bréal. London: Duckworth & Co.

[2] "*Mediæval London.*" By William Benham, D.D., F.S.A., and Charles Welch, F.S.A. London: Seely & Co. Price, 7*s.* 6*d.*

They are wash drawings of places long since destroyed or restored beyond recognition, such as the crypt of a church in Aldgate, which had a fine vault. Those of the Tower are interesting, as showing the old seventeenth-century gabled houses which have been rebuilt as Victorian Norman.

Besides the above drawings are some exquisite pencil outlines by Antonio van der Wyngaerde, reproduced from the originals in the Bodleian Library, at Oxford. They are views of Westminster, the Strand, St. Paul's (the old cathedral), London Bridge, Billingsgate, the Tower, and Greenwich. Another, of Archer's, represents the Roman bath in the Strand, discovered in 1841. How many visitors to the metropolis have any idea that there is a Roman bath in London; indeed, how many Londoners, as they trudge along the Strand, are aware of the fact?

The letter-press is as good as the illustrations, which, of course, we should expect from two notable antiquaries, who are equally at home in relating historic facts as in discussing architecture.

AMONGST the many serial papers that have been first published in this journal and later republished in book-form, the latest now presents itself in the form of a reprint of Professor Edward S. Morse's journal-notes[1] made during a brief visit some years ago to some of the cities of China, at that time more or less open to the inspection of "foreign devils." The papers have too recently appeared in our own columns to require any extended notice of them, but it is worth while to explain that in preparing them for appearance in book-form Professor Morse has added other matter and illustrations, so that the book runs to over two hundred pages of lively, entertaining and instructive reading.

These journal-notes are to be looked on as merely the efforts of a man of science in his hours of relaxation and leisure; they are the plain, unvarnished records of personal impressions during a vacation-trip, jotted down on the spot without thought that they might later be laid before the public. If any one cares to know what Professor Morse's scientific work is he can find it in his important monograph on Brachiapods now in press; or get an equally good and more entertaining impression by examining his great catalogue of the Morse Collection of Japanese Pottery in the Boston Museum of Fine-Arts, one of the most perfect specimens of modern book-making that can be found, and an imposing monument of what scientific accuracy, patient thoroughness and true scholarship can accomplish.

IT has always seemed to us curious and somewhat inexplicable that English draughtsmen should have such a passion for drawing, over and over again in aimless repetition, to seemingly fruitless end, the examples of the heavy old oak furniture of the sixteenth and seventeenth centuries that are to be found in museums and cherished in the domestic circle as reminders of the discomfort endured by the people of those days, and proofs that the artistic perceptions of the designers were hardly on a par with the skill of the workmen who so vigorously carried out the crude ideas of the furniture-designer.

These cherished examples of old oak furniture are wonderfully easy to measure, as the forms are all geometrical and the parts not too small to be accurately figured with the use of a foot-measure, and the ornamentation is so crude that it can hardly be wronged by the most careless and inaccurate sketching. The fact that these heavy and clumsy articles were so well and strongly put together that they have lasted, in spite of hard use and neglect, for two or three hundred years and still are serviceable seems but a poor reason for encouraging furniture-makers in these days to put on the market articles which textually repeat these archaic and clumsy forms. And if the preparation and publication of elaborate measured drawings have not for their purpose the enabling the thoughtless designer or the rule-of-thumb mechanic to reconstruct the article in question, what is their purpose? They may be intended as warnings showing what to avoid; they can hardly be offered as suggestions which invite the designers of to-day to seek a means of refining and adapting their heavy clumsiness to the needs of to-day. Archæological veneration for the archaic work of elder times is respectable, but it is a virtue that the artist of to-day can leave uncultivated without losing caste.

Granted that another book of measured drawings of old English oak furniture were needed, we readily admit that Mr. Hurrell's book[2] fills the gap amply — even handsomely. He has shown all that there is to show, clearly, intelligently and intelligibly, but we question whether a large portion of his time has not been misspent, though we admit that this misgiving may not be shared by others.

The last forty of his one hundred and ten plates are more interesting than those which he devotes to furniture proper. Here we find collected measured drawings of miscellaneous details of the wood-worker's art of the period, panelling, ceilings, mantels, stair-rails, window-finish, etc. The forms are those proper to the period and the archaism of the decoration is essentially similar to that which is employed on the chairs, tables and chests shown in the earlier plates; but they are more interesting, more agreeable, more useful and usable, finally, because the eye accepts them as the mere expressions of form, and does not suggest to the mind heaviness and bodily discomfort as it does in the case of tables, chests and chairs which must be lifted and moved at the expense of a real muscular effort, or used and sat upon to the undergoing of real physical discomfort.

THE old capital of Provence is certainly an imposing city. As one passes through the spacious *Cours*, with its trees and fountains, one is attracted by many fine sculptured doorways, brass knockers and finger-plates. And yet, not a single doorway can be attributed to any particular sculptor — there are no records in the city archives of the buildings, and the names of the craftsmen and sculptors who designed these beautiful doorways are as unknown as the troubadours' who sang at the Court of Kings René or Raymond. But, if artists are known by their works, Aix is a place to go to for the study of doorways; not half a dozen, but dozens, may be seen in all the streets. They are all still known by the names of the original owners, but whether by native artists or strangers, there is no evidence.

Two monuments in the Cathedral, of the fifteenth century, display grotesqueness rather than grace. The Eygosy Monument is interesting as an example of a most benevolent and soft-eyed *Tarasque*, that fearsome beast who, after devouring half the townsfolk of Tarascon, was subdued by S. Martha, and gave its name to the home of our much-respected Tartarin. But neither this nor the group of S. Martin — the beggar and the dog — are above the ordinary work of the period. They are Burgundian in character, whereas the doorways are Italian. The modelling of the caryatides of the Porte de Hôtel d'Espagnet, in the Cours Mirabeau, is superb. In the bas-relief above the door, Rue Espariat, we can trace the spirit of Prud'hon. So similar are these little winged Amours to some of Prud'hon's inventions, that one is almost tempted to assert that he must have designed them and the little people firing the cannon.

NOTES AND CLIPPINGS

THE NEW YORK STOCK EXCHANGE. — Next to the light, the two features of the room which it is of greatest importance should be as convenient as possible are the telephones and the annunciator. At the present time, Exchange members have about 500 telephones on the floor. In the old building they were placed everywhere that room could be

found for them. In the new structure, however, the greatest attention has been paid to placing the telephones in the most convenient possible location on the floor. The instruments are to be placed against a row of parallel partitions at the New Street end of the floor. They also encircle the great piers at that end which support the ceiling and floors above. An extraordinary amount of time and ingenuity was expended in planning these telephones so that every inch of space should be saved to the main floor and so that the clerks who operate the instruments should not be in the way of the brokers on the floor. To that end it has been arranged that these clerks shall enter the Exchange by their own door. They will not come into contact with floor-members except when it is necessary to the transaction of business. Second in importance only to the telephones is the annunciator. In the old Exchange Building the annunciator was a huge checker-board contrivance stretched across one wall. There were 1,200 squares — one for each member and officer — with a number on each. When a member was wanted at the telephone, his clerk would press a button, the flap covering his number would fall, and the member would run to his telephone to get the message. It is obvious that on a floor where perhaps 1,000 men are moving about it is not easy to locate any one, so that in the expeditious discharge of business these annunciators form an essential factor. In the new building there is a most ingenious contrivance. In each of the two side-walls of the room, other than those made by the windows, there is a great oblong checker-board, of 1,200 rectangles, each 9″ x 12″ in size. These rectangles are made of opaque glass and upon each of them a member's number is painted in distinct numerals. Behind each square are several incandescent electric-bulbs, with bulbs of different colors. Any one of the bulbs may be operated by the member's clerk. If the member is wanted at the telephone a red light may be turned on. If he is wanted at his office immediately, a green one. If some one wants him at the entrance, a blue globe. By alternating the colors, by duplicating flashes, and by other variations, it is obvious that an almost unlimited number of messages may be flashed to a member on the floor. In a business where seconds often count for everything, it will be pos sible to save a vast amount of time and money through this form of annunciator. One of them is fixed on each wall to save the members from looking one way all the time. Under the old system, the eyes of many members were injured from the necessity of continually looking at a single flapping checker-board. — *Ivy Lee in the World's Work.*

New Facts about Cliff-dwellers. — Dr. Henry M. Baum, President of the Records of the Past Society of Washington, D. C., has recently returned from a two months' visit to the ruins of the cliff-dwellers in Colorado, New Mexico, and Arizona, and will recommend that three groups of ruins — the Mesa Verda, near Mancos, Col.; the Chaco Cañon, in New Mexico; and the Cañon de Chelly, in the central part of Arizona — be set aside by Congress as national reserves. He is opposed to the project which is being agitated to set aside 480,000 acres which constitute Jaurito Park, near Española, in New Mexico. He will also urge Congress to order an archæological survey of the Southwest. He will return to Colorado next summer, and will head an expedition which will go over the territory just covered in a more comprehensive and detailed manner. He asserts that the cliff-dwellers lived at least 1,000 years ago, and, possibly, half a century earlier, while evidences exist of the habitations of many millions of people. In speaking of his trip, Dr. Baum said: "During my trip I do not think that I averaged 10 miles in any one of the cliff-dwellings districts where I did not come across some of the habitations in which these prehistoric people lived. I saw on my entire trip enough dwellings to accommodate 2,000,000 people. From what I saw I believe the country must have been inhabited by at least 7,000,000 persons. I am firmly convinced of one fact, and that is that the cliff-dwellers and the mesa and valley dwellers were all of a contemporaneous civilization which dates back before the heavy lava overflow in the Southwest. The pottery, stone implements, and skulls found in these three classes of ruins are all the same. It is quite evident that the vast civilization of the entire country was extinguished by a flow of lava, an eruption similar to that which recently occurred at Martinique. Those who were not killed directly by the lava-flow succumbed to the pestilence which followed. There were numerous evidences of the lava-flow throughout the entire region. In one instance I saw a vast irrigation-ditch filled with lava, and in New Mexico there were numerous dwellings covered with it." — *N. Y. Evening Post.*

Sea-water and Portland-cement Concrete. — A series of experiments, which are expected to extend over a period of 30 years, are about to be undertaken by the Prussian Government, in conjunction with a number of prominent cement-manufacturers, with a view to further elucidating the effect of sea-water on Portland-cement concrete. A number of large concrete blocks, made with cements of different compositions, are to be sunk in the sea off the coast of Sylt Island, and will be examined periodically. At the same time, briquettes of the mortar used and blocks of the concrete will be immersed in tanks on the land. Some of these tanks will contain fresh, and some salt, water. Both tensile and compressive tests of these briquettes and blocks will be made from time to time. The mortars used will be compounded so as to determine whether an addition of slags or strass improves the resistance of the cement to sea-water. It must be mentioned here that both high-limed and low-limed cements are to be used in these tests. — *Stone Trades' Journal.*

Valuable Find in Bœotia. — In a report to the Department of State, Charles S. Francis, United States Minister at Athens, Greece, announces that an unusually interesting archæological discovery has just been made in the northern part of Bœotia, in a plain of Chæronea, where the Greeks in 338 B. C. lost their independence by their defeat by Philip of Macedon. Mr. Francis says: "Dr. Soleriades had been sent there to examine the ruins of an ancient monument which the Greeks had erected on the spot where they had buried the fallen. In making a tentative examination he found a low tumulus on exactly the spot where Plutarch places the burial-place of the Macedonian soldiers of Philip. This tumulus he opened and found therein the remains of the Macedonian dead packed in layers. Most of the bones are charred, and the soil is mixed with ashes, showing that the bodies were cremated imperfectly. The importance of the discovery is that topographers will be able better to identify the sites of the battlefield, archæologists will expect to find Macedonian accoutrements, etc., and ethnologists, by studying the skulls (some well preserved) will be able to come to some conclusion regarding the racial affinities of the ancient Macedonians." — *Exchange.*

Purification of Water by Ozone. — "An examination of the results obtained in the purification of water by treatment with ozone has just been concluded by Drs. Ohlmuller and Prall, on behalf of the German Imperial Health Department," says the *Electrical Review.* "The apparatus used was capable of treating 10 cubic metres of water per hour. The water was sprayed through a rose to a bed of pebbles, beneath which ozonized air was forced under pressure. The down-flowing water thus came into very intimate contact with the up-flowing current of air. Bacteriological examinations were made both before and after treatment, while the effect of the process on color, clearness, and taste of the water was also observed. The bacteria which survived appeared to be of a specially resistant type, since their number was not reduced by prolonging the ozonizing action. It was found that the whole of the pathogenic bacteria were entirely destroyed by the process. None of the germs of cholera or typhus species survived. The process improves the color of the water and has no bad effect on the taste. The cost is given at about 5 cents per thousand gallons, one-third of which represents the actual cost of ozonizing."

Raising the Level of the Great Lakes. — The Government's determination to investigate a feasible plan of maintaining, if not lifting, the present level of the Great Lakes has caused a great deal of comment in marine circles of this city, and has aroused great enthusiasm at all other lake-ports, and progress of the movement will be watched with great interest. Congress has made financial provision for the undertaking, and it is understood that the experts who will carry on the investigation will be appointed at an early date. The question of the practicability of such a plan is not altogether new, but it appears that former experiments along those lines have never been carried far enough, because until very recently there has been ample depth of water at various ports and through the rivers and channels connecting them. During the last few years, however, vessel-men say lake-levels have dropped at an alarming rate, and the point is now reached where much fear is expressed for the future of commerce. The condition becomes more noticeable, marine interest contends, since the tendency of ship-building is toward the larger and deeper-draught craft. Experts claim that Lake Michigan has shown greater shrinkage, and old sailors bear out this statement. Some have claimed that the drainage-canal is largely to blame for the recent low water in Lake Michigan, although engineers of the latter scout the theory. It is understood, however, to be part of the Government's plan to investigate this particular condition. Many plans and suggestions are offered as reparatives. The one most talked of by practical marine men and engineers is that of building a dam at some point upon the lower waters of the Lakes, likely Lake Erie, near Niagara. Prominent engineers who have given the problem some study take the ground that it may be practicable to erect such a dam, and that the water could be raised fully 3 feet in Lake Erie thereby. The effect of such an elevation, it is held, would be felt in Lake Huron, but in lesser degree, the water being raised perhaps 2 feet. It is not obvious how such a plan would materially benefit Lake Michigan, and this point is causing much discussion. Some claim that the latter's level would be raised a foot by such an undertaking, although experts are aloof on that reasoning. Marine interests fear that the Government will be many years in getting down to actual work of relieving the condition of low water, for the project will cost many millions. It is argued that the saving made by the elimination of the necessity of dredging harbors and rivers, for which the Government lays out large sums every year, would be vast and in time would greatly offset the original expenditure. Marine interest maintains that something must be done or the next decade will see a revolution in the great inland waterways and their commerce. — *Chicago Inter Ocean.*

What is Bird's-eye Maple? — "What is bird's-eye maple?" That is a question which just now seems to be baffling not only people who use furniture made of this particular wood, but even woodworkers themselves. In a recent number of a woodworking-magazine an article was published which stated that bird's-eye maple was not a peculiar maple, but simply ordinary maple cut in a certain way. In a recent issue of the New York *Sun* that statement is refuted. It is there stated, on the authority of a woodworker, that bird's-eye maple and curly maple are both cut only from the logs of the rock-maple tree, *Acer saccharinum,* in which a beautiful lustrous grain is produced by the sinuous course of the fibres. This tree is not at all the common hard maple. It is a hard maple, but is full of little gnarls called eyes. Men looking for bird's-eye maple logs go through the standing timber and pick out the bird's-eye maple-trees, paying for them from $30 to $50 a thousand feet in the woods. Ordinary hard maple logs are worth only from $6 to $7 a thousand feet. It would be impossible to cut a piece of veneer with eyes in it from a common hard maple log, and it would be equally impossible to cut a bird's-eye maple-log, no matter how you cut it, so that it would not show the eyes." — *Scientific American.*

NOTES AND CLIPPINGS. 48

A VERY interesting discussion has been going on in the New York *Evening Post* about American indifference to art. The *Evening Post* says, not without reason, that Americans look upon art with an intellectual, rather than an æsthetic eye, and it pleads for a greater appeal to the sense of beauty than is usual in our sculptured monuments, lamenting that our sculptors are obliged to spend their time in modelling the trousers and hats of their subjects, to meet the taste of their patrons, instead of endeavoring to charm spectators by some beautiful accessory. To artists and architects, familiar with the lovely and affecting French monuments, such as that to Regnault, in the School of Fine Arts, at Paris, or the Maupassant monument, in the Parc Monceau, or scores of others, it certainly seems as if something might be done to relieve the dryness of such portrait sculpture as we see everywhere in New York, and Boston, and Washington; but we are not sure that it is the public taste alone which is responsible for the devotion of our portrait statues to pantaloons. On the contrary, the attempts of Mr. St. Gaudens to add ideal accessories to his portraits have been warmly applauded by the American public, which is, we venture to say, quite ready to receive with favor further efforts in the same direction. Moreover, it should not be forgotten that it is possible to idealize a very simple portrait, if the sculptor has within himself the material for such idealization. No living sculptor, for example, is more successful in what we may call ideal accessories than Mercié, yet Mercié, in his Lee monument at Richmond, has been able to make a simple portrait, without accessories, unless the horse on which the great general sits can be called an accessory, as noble and inspiring as if he had surrounded it with representations of all the gods of Olympus. The *Evening Post* says, with truth, that "it would do no harm if our sculptors were occasionally asked for something more specifically sculpturesque than a portrait statue," but it does not follow that a great artist cannot show his greatness in portrait statues. He may not be able to reach perfection in portraiture, without that personal acquaintance with his subject which sculptors rarely possess; but he can make a perfect portrait of his ideal of his subject, and in the nobility of his ideal, and the power with which he expresses it in his figure, he may reach the highest flights of art.

IT may be worth inquiring whether the transformation which is going on in our periodical literature does not indicate an approaching artistic movement. Undoubtedly, the transformation is due to the invention of cheap processes of photographic reproduction, but the question of its origin does not affect the fact that where our predecessors were content with printed descriptions of interesting objects, we are supplied with accurate photographic representations of them. Every murderer, every great banker, every distinguished beauty, every interesting scene, is displayed before our eyes in endless half-tone prints, which, while they have little pretension to be artistic, are, at least, truthful; and it is not impossible that our habit of seeing accurate representations of all sorts of objects may be preparing us for a sense of that truthfulness which is the essence of art. Even now, the long necks and rosebud mouths of the idealized portraits of a hundred years ago look to us ridiculous in comparison with the actual human countenance as we see it drawn by the action of light on the pages of the daily newspapers; and the increase of our knowledge of the actual appearance of objects must make us more critical of artistic incapacity. Meanwhile, as if the publishers had observed a change in the public demand, the covers of magazines, and even the inside pages of Sunday newspapers, have begun to blaze with color. Undoubtedly, this is used, to a certain extent, to attract the eye of customers, unable to choose among the multitude of magazines offered for sale; but, even twenty years ago, a loud design in black and white would have been thought sufficient for a purpose for which the richest colors, combined with great skill, are now requisite. We are far from thinking that all the bright-colored magazine covers are artistically successful, but they are rapidly improving, and in them the coming generation is receiving a lesson which must have its effect sooner or later.

EVERY architect will regret the sudden death of Walter Cope, of Philadelphia, one of the most distinguished and popular members of the profession. It is something like twenty years since the firm of Cope & Stewardson came into note among architects all over the country for their beautiful and original work, as shown in the professional periodicals, and every year may be said to have added to their reputation. Some years ago, John Stewardson, the original Stewardson of the firm, was drowned while skating, to the deep regret of the community, as well as of the profession, but the firm name was continued, his brother taking his place, and has gained still more in note throughout the country. Mr. Cope was deeply interested in professional matters, and always ready to sacrifice himself in defence of the honor and rights of architects; and his loss will be felt among his brethren as that of a brave and wise defender of their interests, as well as of a beloved comrade.

MANY architects, particularly in Boston and New York, will hear with great regret of the death of Frederic Tudor, well known in the profession as an engineer for works of heating, ventilation and sanitation. Mr. Tudor belonged to an old and wealthy Boston family, and spent a considerable part of his boyhood abroad, returning from Paris to enter Harvard College. He was an earnest student of physics, and of science generally, and, on his graduation from college, entered immediately the service of the Boston and Maine Railroad, as a civil engineer. His health, even then, was delicate, and he found it necessary to give up a position in which he had already distinguished himself, and go back to Europe, where he interested himself in the movement for sanitation which was then at its height in England. On his return to this country, he undertook to put in practice the new ideas which he had received abroad, with improvements of his own, and, establishing himself as a consulting engineer in matters of heating, ventilation and drainage, he soon gained an extensive practice. Unfortunately for him, his enthusiasm for science led him to undertake contracts for work of the kind, in which, while he could better secure the execution of the work in the way in which he wanted it done, he was exposed to business hazards which he was hardly fitted by nature or experience to guard against, and, after some years of honorable effort, during which he introduced immense improvements, both in system and in detail, in the practice of heating and ventilation, he was forced into insolvency, with the loss of all his modest inherited fortune. He was, however, too valuable a man in his profession to be lost sight of, and his services as consulting engineer were soon in great demand. Under his advice, or from his designs, were installed the heating and ventilating system, to our mind unrivalled in the world, of the Metropolitan Opera House, in New York; the Pittsburgh Court House; the Boston Public Library; the Roxbury High School, and a great number of other buildings, public and private. He was, at the

Copyright, 1902, by the AMERICAN ARCHITECT AND BUILDING NEWS COMPANY, Boston, Mass.
Entered at the Post-Office at Boston as second-class matter

same time, often called in consultation in regard to matters of drainage, upon which he was also an accomplished expert; and, in connection with his brother-in-law, he established a system of inspection and guaranty of plumbing and drainage which the profession has found of great service. Although he had suffered for many years from unmistakable pulmonary disease, his enthusiasm for his work kept him actively employed until within a few months, and it is said that even on his death-bed his mind was still busy with new inventions, which he was never to see carried out.

PROFESSOR GOODYEAR, of the Brooklyn Academy of Arts and Sciences, has been making an extremely interesting study of a Renaissance leaning façade, that of the church of S. Ambrogio, at Genoa, which was built in the latter part of the sixteenth century, probably about 1590, and shows, in the lower story of the front, an inclination forward of about eight inches, the story above being vertical. That the forward inclination was intentional is shown beyond question by the fact that the return pilasters show base-mouldings perfectly horizontal, which form an obtuse angle with the front edge of the pilaster, and an acute angle with the other edge. This observation of Professor Goodyear and his party, made in 1901, was subsequently confirmed by the official architect of the church, Signor De Andreis, who, it appeared, had noticed and measured the inclination ten years before, on the occasion of certain repairs and alterations.

THIS discovery is of peculiar value, as confirming the results of Professor Goodyear's study of the Cathedrals of Pisa and Ferrara, and the churches of S. Ambrogio, at Milan, S. Michele at Pavia, and Notre Dame at Paris, the fronts of all of which have the lower portion inclined forward, although, in most of them, the walls above are vertical. It is interesting, also, to learn that the lower tier of columns adorning the front of St. Mark's Church at Venice lean forward about three inches, in a height of something over nine feet, although the wall behind them is vertical, as are also the columns of the tier above; while the Porta della Carta, in the courtyard of the Palace of St. Mark, leans forward as a whole, the inclination being about eight inches. The Porta della Carta is a work of the early Renaissance, or, at least, of the Transition, so that this, with the much later front of S. Ambrogio at Genoa, indicates that the practice of curving or varying lines and surfaces to correct the effect of perspective, or to give certain artistic qualities, was not confined to the architects of the Middle Ages, but persisted, in a certain degree, far into the Renaissance period.

THE exact purpose of these variations from geometrical accuracy can only be conjectured. Undoubtedly, the practice of inclining forward the lower portion of the front of a building contributes to the peculiar advancing effect characteristic of many mediæval churches, but whether this effect was aimed at, or whether the walls were inclined for some other purpose, we cannot say. In the case of S. Ambrogio at Genoa, and of the Porta della Carta at Venice, it is probable that the inclination was given to allow the sculptured detail to be seen more fully, and with less change from foreshortening, just as the pinnacles and statues on the top of St. Mark's lean forward, the pinnacles overhanging more than six inches, and as friezes have been inclined forward, even down to our own time; but there is nothing in the lower portion of the front of Notre Dame, at Paris, which could be better seen in an inclined wall than in a vertical one, nor are the nine-foot columns of St. Mark's more favorably placed, in this respect, than they would be in a vertical position; so that we must, perhaps, conclude that the bulging effect was sought for its own sake, possibly as a correction of the flatness and dryness which the architects of the Middle Ages seem to have disliked so much.

THE State of Minnesota has a law under which any person or corporation owning bare, waste, sandy, rough or rocky lands, or denuded forest tracts, may convey such lands by deed to the State, for forestry purposes; and all lands so deeded are to be forever dedicated to forestry. The statute further provides that one-third of the revenue from such lands shall be divided between the State, county and town in which the forest is situated, in lieu of taxes, and the remaining two-thirds shall be paid to such public educational institution in the State as the grantor may designate. Under this law the late Governor John S. Pillsbury very generously conveyed to the State a tract of a thousand acres of land, once covered with forest, which would have been available for grazing, and even for farming, but which was also particularly well adapted for the experimental forestry which the donor desired to aid in carrying out. This tract is now in charge of the State Forestry Board, and will, it is hoped, form the nucleus of an extensive and profitable public forest. There are many other States in which a law similar to that of Minnesota might prove very useful. Millions of acres in the Eastern States, particularly, are nothing but a burden to their owners, who cannot profitably cultivate them, and whose attempts to plant them with trees, if they are enterprising enough to make any such attempts, are hampered by the smallness of the area with which they have to deal, and the indifference of their neighbors. The owners of these lands are too proud to abandon them, and, in consequence, continue to pay taxes on them, year after year, without the smallest prospect of ever receiving any return. Under the Minnesota law, such owners could relieve themselves of this burden, at the same time that they gained credit for themselves, by conveying the useless land to the State, and, incidentally, might confer great benefits on their posterity, or, rather, on the community of which their posterity would form a part; and it is conceivable that, by reserving some of the more available land out of a large tract, the remainder of which was conveyed to the State, the value of the portion reserved might ultimately be so much enhanced by the vicinity of a productive and well-kept forest that the operation would be a profitable one to all concerned.

THE French professional journals inform us that the Count de Castellane has bought from its former proprietor, an enthusiastic antiquarian, the celebrated Château de Grignan, long associated with the name of Madame de Sévigné, who spent there the last years of her life, with her daughter, Madame de Grignan. The husband of the latter, after his appointment as Governor of Provence, was obliged to maintain a style of living too magnificent for his comparatively modest fortune, and many of the letters of Madame de Sévigné, who was much attached to the husband of her beautiful daughter, relate to the construction of the château, a part of which dated from the time of Francis I, while the more modern portion was built under Louis XIV, from the designs of Mansard. As M. de Grignan found himself unable to carry out the plans of Mansard from his own resources, his two brothers, the Bishop of Carcassonne and the Bishop Coadjutor of Arles, came to the rescue, and supplied the funds required for the completion of the work. Unfortunately for the comfort of the people who lived in the house, the construction of the new portion, the "Bishops' Wing," as it is still called, went on very slowly, partly from the irregularity of payments, but still more on account of the caprices of the two Bishops, who made continual changes in the plans, "like little girls," as Madame de Sévigné says, who embroider on canvas, and "immediately pull out what they have done"; and the amiable Marquise did not hesitate to call vigorously upon the reverend gentlemen to finish the building, or, at least, to get it enclosed, so as to keep out the winds which rushed furiously through it. Her appeals seem to have been heard, for the "Bishops' Wing" was at last finished, and Madame de Sévigné lived for many years in the room which is still shown as hers, and, after her death, which took place in the château, was buried in the little church on the estate. All this took place nearly two hundred years ago, and the "Bishops' Wing" is now falling to decay, while the Francis I portion of the castle, nearly two hundred years older still, has almost disappeared; but the castle is so highly valued in France that it is officially classed as an "historic monument," and, although the Government was unable to purchase the property, it is hoped, undoubtedly with reason, that the new owners will respect, as far as possible, the associations of the place.

THE late Henry G. Marquand has been succeeded, as President of the Metropolitan Museum of Art, by Frederick W. Rhinelander, who has been for more than thirty years connected with the Museum as Trustee or Vice-President. Mr. Rhinelander is a connoisseur of great experience, and the active interest which he has taken in the affairs of the Museum, ever since its incorporation, makes it probable that the conservative but enlightened policy which has done so much for the Museum will be continued during his administration.

NOTES ON IRON AND STEEL CONSTRUCTION.[1] — XI.

THE steel-beam grillage-footings described in the previous article are exceedingly expensive on account of the great weight of steel required in their design. In the effort to obtain a spread footing that would possess the advantages of a steel-beam grillage-footing and at the same time be reasonable in cost, the reënforced concrete footing was studied and adopted to a considerable extent. This type of footing is shown in Figure 79 and consists of a monolithic concrete footing reënforced by tension-bars of metal as shown at *a* in the figure. The reason for thus reënforcing the concrete is due to the fact that while concrete has a great compressive strength, it offers comparatively little resistance to tension, so that in order to more nearly realize the compressive strength of concrete when a slab is subjected to transverse stress, the tensile resistance is supplied by the insertion of wire-netting, expanded-metal, twisted or corrugated rods of steel. The principal reason for using these forms of steel consists in the fact that the adhesion between the metallic reënforcement and the concrete must be sufficient to realize the tensile strength of the metal, that is, if the reënforcing-rods should slip and the joints between the concrete and the metal be thus destroyed, its efficiency as a reënforcing element would be materially lessened. The greatest use of reënforced concrete has previously existed in the construction of fireproof floors, arched bridges, concrete retaining-walls and similar structures. The slab of concrete reënforced with metal as shown in Figure 80 will deflect to a great extent before any signs of fracture or cracks can be detected on the under side of the slab, and it has been stated by some authorities that concrete slabs reënforced with metal do not crack until the point of rupture is nearly reached and also that the tensile-stress in the under surface of the slab and metallic rods does not decrease with excessive deflection and remains nearly constant until rupture occurs.

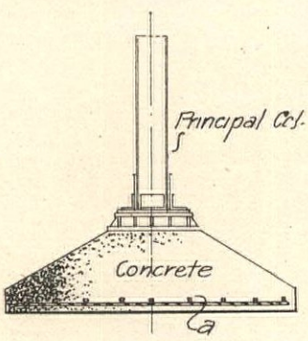

Fig. 79.

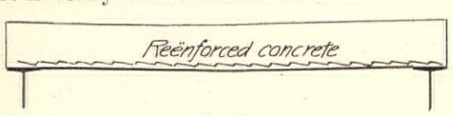

Fig. 80.

In reënforcing concrete that it may resist transverse stress, there have been employed several metallic forms. The common forms of metallic reënforcing bars are shown in Figures 81, 82, 83 and 84. In Figure 81 is designated a system of reenforcement which consists of heavy metallic wires crossed and recrossed until they practically form a woven-wire netting. This system of reënforcement is distinctly French. In Figure 82 is shown a twisted bar of iron and the introduction of this bar in concrete slabs is known as the Ransome system of concrete-construction. This bar is provided with a twist, the idea being that it will be held more tenaciously within the body of the concrete and no danger of slipping will exist. Another form of concrete reënforcement consists in the embedding of expanded-metal lathing in the under portion of the slab. The expanded-metal and the method of using it for this purpose is shown in Figure 83. The manufacturers of expanded-metal make a particularly extra heavy type of metal for this purpose. The metal may be obtained either of black or galvanized soft steel.

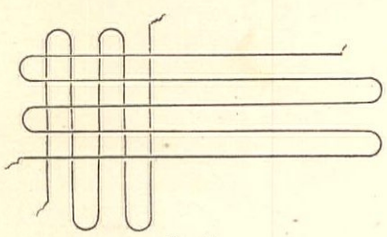

Fig. 81.

In Figure 84 is shown a type of rolled bar which has recently been introduced for the reënforcement of concrete under transverse-stress and which is admirably adapted for the purpose of building foundations. This bar is corrugated or ribbed in rolling and the angle made by the sides of the ribs with a plane at right angles to the axis of the bar is less than the angle of friction between the metal and the concrete. By this means the liability of the loss of strength in the reënforced slab, due to the breaking of the adhesion between the concrete and the metal, is necessarily eliminated. It is questionable, however, whether these corrugations or ribs need be provided in order that the adhesion between the concrete and metal bars be sufficient to realize their tensile strength. By experiment and tests plain bars of iron embedded in concrete have developed surprising adhesive resistance and many important works have been built abroad in which simple plain iron, round or square bars without twist or corrugations, have been used. Undoubtedly, the corrugations and the twists of the bar in the Ransome system are safeguards against any possible slipping and it may be that the efficiency of the plain bars used in the construction abroad depended entirely upon the fact that there was a great difference between the working-loads and the ultimate strength of the structure.

Fig. 82.

In order that one can intelligently design concrete foundations reënforced with steel rods, it is important that they should understand the present theory of the transverse strength of steel and concrete in combination. It is necessary in the design of spread footings that the transverse strength be known, for on account of the small area of the column base and the great area of the footing there is a tendency for a spread footing of shallow depth to fail by rupture adjacent to the perimeter of the column base. In the study of the transverse strength of steel and concrete in combination, it is requisite that one should have a clear understanding of the term *modulus of elasticity*.

It has been found by experiment and test that in all elastic materials subjected to stress and deformation the elongation under tension or the shortening by compression is directly proportional to the stress, within the elastic limit of the material. The *elastic limit* of the material is the load at which the deformation is not directly proportional to the *stress*. The *modulus of elasticity* in all formulas of the strength of materials is usually represented by E and $E=\frac{s}{d}$. In this formula $s=$ the stress, that is the pull or compression in pounds per square inch; $d=$ the proportional change or deformation per unit of length. The value of s is always equal to the amount of the force acting upon the material, divided by the area of the cross-section of the material, while d equals the total length of the member, bar or material in the direction of elongation or in the direction of deformation, divided by the amount of distortion or deformation, so that the value of E may be expressed by the formula

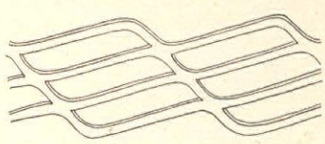

Fig. 83.

$$E=\frac{\frac{S}{A}}{\frac{l}{L}}=\frac{SL}{Al}.$$

In the application of this formula, assume that a force of 120,000 pounds applied to a structural-steel tension member, whose length is 120 inches and whose cross-section is 2 square inches, produces an elongation equal to .24 inches, the problem being to determine the modulus of elasticity of the steel. According to the formula

$$E=\frac{SL}{Al}$$

and by substitution it becomes $\frac{120{,}000\times 120}{2\times .24}=30{,}000{,}000$.

In composite beams of steel and concrete the nature of their section is not homogeneous and the steel does not possess the same elasticity as the concrete. While the modulus of elasticity of steel has been determined as between 28,000,000 or 30,000,000 pounds, this value of concrete has not been definitely ascertained. The value varies with the particular quality of the concrete employed and with its age. It is considered by good practice, however, that 1,000,000 is the safe value for the modulus of elasticity of Portland-cement concrete having aggregates of slag or broken stone, while cinder-concrete possesses far less

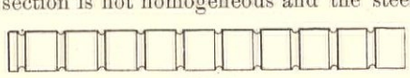

Fig. 84.

[1] Continued from No. 1395, page 95.

strength and probably its modulus of elasticity does not exceed 150,000. This latter concrete is mostly used for fireproof floor-construction and would never be used in the construction of foundation footings, so that it may be dropped from the discussion. In a composite beam it must be assumed that each material making up the section offers a resistance proportional to its rigidity, and it may likewise be stated that the rigidity of steel and concrete having like areas is proportional as the ratio existing between their moduli of elasticity, or, since the rigidity of the concrete is expressed by 1,000,000 and the steel by 28,000,000, that equal strain or deformation will be created in the concrete and steel when there is 28 square inches of concrete similarly placed with respect to the neutral axis as one square inch of steel. Therefore, in order to determine the resistance to transverse stress of a beam combining steel and concrete, it is reasonable to *redraw* the section of the beam and substitute, on a line coincident with the steel bars, an area of concrete which will be equal to them in resistance. This will be made clear by reference to Figure 85, which shows a concrete footing reënforced with four steel

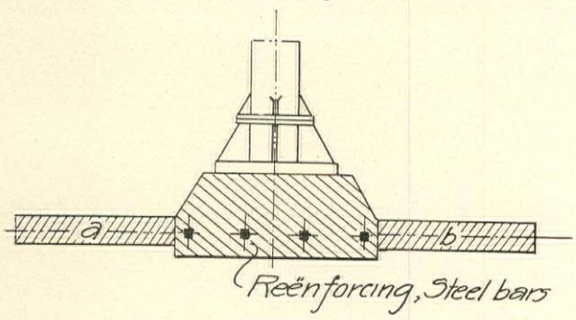

Fig. 85.

bars. Considering that the steel bars are omitted and substituting in their stead the areas a and b, which are equal in extent to 28 times the sectional area of the bars, the neutral axis may be determined by calculation, and found where shown in the figure. The moment-of-inertia may then be calculated and the strength of the footing or beam determined when the *beam* fails by cracking on the tension side, by the formula $M_1 = \frac{s\,I}{c}$. In this formula M_1 = the moment-of-resistance of the section, s = the safe unit fibre-stress, that is, the safe unit tensile-stress of the concrete, I = the moment-of-inertia of the new section and c = the least distance from the neutral axis of the extreme fibres on the tension side.

When the bending-moment is known it is usually necessary to determine the compressive stress at the top of the concrete and the tensile stress at the bottom of the concrete and these values, which may be represented by Sc and St respectively, are obtained from the following formulas: —

$$Sc = \frac{M c_1}{I} = S\left\{\frac{1 + m - 2\frac{d_1}{d}}{1 + m + 12\frac{{d_1}^2}{d^2}}\right\}$$

$$St = \frac{M c_2}{I} = S\left\{\frac{1 + m + 2\frac{d_1}{d}}{1 + m + 12\frac{{d_1}^2}{d^2}}\right\}$$

In the above formulas the value of the algebraic symbols are as given in the following notation: —

I = moment-of-inertia of the altered cross-section.

S = stress in the extreme fibres of the unenforced concrete section which may be found by the formula $\frac{6\,M}{b\,d^2}$

E_s = modulus of elasticity of the steel reënforcing rods or bars.

E_c = modulus of elasticity of the concrete in the beam section.

b = width of the concrete beam.

d = height.

a = sectional area of the steel reënforcing bar or rod.

A = sectional area of the concrete substituted instead of the steel reënforcing members, which is equal to $a\frac{E_s}{E_c}$

d_1 = distance from central axis of the original beam-section to the centre of the reënforcing bar.

d_2 = distance from central axis of the original beam-section to the new neutral axis of the altered cross-section.

c_1 = distance from the neutral axis to the tension side of the beam.

c_2 = distance from the neutral axis to the compression side of the beam.

m = ratio of the longitudinal rigidity existing between the concrete beam and the steel reënforcing member imbedded within its lower portion; this value of m is equal to $\frac{b\,d}{a} \times \frac{E_c}{E_s}$

The values of d_2, c_1, c_2 and I may readily be worked out by the following formulas: —

$$d_2 = \frac{l}{m+1}$$

$$c_1 = \frac{d}{2} - d_2$$

$$c_2 = \frac{d}{2} + d_2$$

$$I = b\,d\left(\frac{d^2}{12} + \frac{l^2}{1+m}\right)$$

In connection with this subject of combination concrete and steel beams, and concrete spread-footings reënforced with steel tension members, the Expanded Metal Fireproofing Company gives valuable data in their several publications. Especially interesting is an article entitled "Discussion of the Strength of Steel-Concrete Beams," which is an abstract from a paper presented to the American Society of Civil Engineers, by A. L. Johnson. This discussion, since it seems one of the most reasonable and practical, is given in connection with this article, and reads as follows: —

"It is a peculiar fact that, though plain concrete beams will deflect but very little before rupture on the tension side, the same concrete when it has a metal reënforcement on this side will deflect enormously before any cracks are noticed, even if the under side is plastered to a perfectly smooth surface. Some authors go so far as to say that the concrete does not crack when armed with metal until near rupture, and that it retains a nearly constant tensile strength after exceeding the distortion at which it should have failed.

It is possible that this is true, but it is a position not as yet generally accepted amongst engineers. As a matter of fact, however, it makes very little difference, as it unquestionably is a fact that the cracks, if present, are so small as to be invisible, and no injury to the construction could result from their presence. If present, we should have to omit from our formula for the moment-of-resistance of the cross-section the moment due to the tension in the concrete below the neutral axis. But as the tensile strength of the concrete is very small anyway, the omission of this element would not materially alter our design.

For this reason, and to avoid a quibble over an unimportant matter, we have assumed that the concrete below the neutral axis is inoperative.

We also assume that very little more than the elastic limit strength of the metal will be developed at the maximum load-carrying capacity of the construction. In testing it is possible to break the metal entirely in two, but this does not occur until after the maximum load-carrying capacity has been passed.

In bar construction therefore, we should use as high a steel as consistent with sufficient ductility, in which case we can readily obtain an elastic limit of from 40,000 to 45,000 pounds per square inch, which would allow us to use about 50,000 in our formula. In the expanded-metal the elastic limit has been much increased by the stretching of the metal in expanding so that the foregoing figure is not far wrong for this material also.

With these values the assumption is made that the modulus of elasticity of the steel is practically constant up to the maximum load-carrying capacity of the construction.

This condition, however, does not hold for the concrete. The maximum load-carrying capacity will occur when the extreme fibre-stress on the concrete is equal to its ultimate compressive strength, assuming that there is enough steel used to develop it. When this occurs the stress diagram will be as shown above the neutral axis in Figure 86. On this diagram the total stress Pc, equal to the area of the shaded portion, is

about 25 per cent greater than the area between the lines $o\,n$ and $o\,s$. This is true either for rock or cinder concrete. Also the modulus of elasticity as represented by the tangent of the angle $n\,o\,s$ is only $\frac{2}{3}$ in rock concrete, and $\frac{1}{2}$ in cinder concrete,

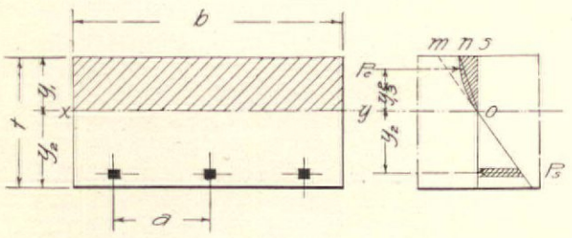

Fig. 86.

as much as the original modulus shown by the tangent of the angle $n\,o\,s$.

With these preliminary conditions disposed of, we are ready to derive the formulas for the moment-of-resistance of steel-concrete slabs.

Let,

E_s = modulus of elasticity of steel in pounds per square inch.

E_c = modulus of elasticity of concrete in compression in pounds per square inch.

F = elastic limit of steel in pounds per square inch.

f_c = compressive strength of concrete in pounds per square inch.

b = width of section considered in inches.

t = thickness of section considered in inches.

d = spacing of bars in inches.

a^2 = area of bars in square inches.

$\frac{a^2}{d}$ = amount of metal per inch of width in square inches.

For No. 16 Ga. 2½-inch mesh expanded-metal this = .012 square inches.

For No. 10 Ga. 3-inch mesh expanded-metal this = .016 square inches.

Mo = moment of ultimate resistance of cross-section in inch-pounds for failure in tension.

M^1o = moment of ultimate resistance of cross-section in inch-pounds for failure in compression.

M = bending-moment of external forces in inch-pounds.

W = total load on beam in pounds.

w = load per square foot uniformly distributed in pounds.

P_s = total stress on metal in width b.

P_c = total stress on concrete in width b.

e_1 = unit elongation of extreme fibre in compression.

e_2 = unit elongation of steel.

We will use the following values for the constants, based upon the best information obtainable. The values for concrete are taken from a very thorough discussion of this subject in the September number of the *Journal of Engineering Societies* for 1900, page 145. They are for an age of one month, this being the age at which tests are usually called for.

E_s = 30,000,000.

E_c = for rock-concrete 1 : 3 : 6, 4,800,000.
for cinder-concrete 1 : 3 : 6, 1,000,000.

F = 50,000.

f_c = for rock-concrete 1 : 3 : 6, 1,500.
= for cinder-concrete 1 : 3 : 6, 600.

b = 12 inches.

d^2 = for ½-inch-square corrugated bars = 0.21 square inches.

The general discussion for single-span beams on knife-edge supports is as follows : —

Total area of metal in width $b = \frac{a^2 b}{d}$.

Total stress on metal, $P_s = \frac{F a^2 b}{d}$.

Then the strain, or stretch, of the metal is $e_2 = \frac{F}{E_s}$,

and $P_s = E_s e_2 \frac{a^2 b}{d}$.

On the compression side we have

$e_1 = e_2 \frac{y_1}{y_2}$, and the resulting stress is

$f_c = e_1 \frac{2 E_c}{3}$ for rock-concrete, and

$= e_1 \frac{E_c}{2}$ for cinder-concrete

$= e_2 \frac{y_1}{y_2} \frac{2 E_c}{3}$ for rock-concrete, and

$= e_2 \frac{y_1}{y_2} \frac{E_c}{2}$ for cinder-concrete.

Also,

$P_c = \frac{5}{4} f_c \frac{b}{2} y_1$ for both rock and cinder concretes.

Then

$P_c = \frac{5\, b\, y_1^2\, e_2\, E_c}{12\, y_2}$ for rock-concrete

$= \frac{5\, b\, y_1^2\, e_2\, E_c}{16\, y^2}$ for cinder-concrete.

But

$P_c = P_s$.

Hence,

$E_s e_2 \frac{a^2 b}{d} = \frac{5\, b\, y_1^2\, e_2\, E_c}{12\, y_2}$ for rock-concrete;

from which

$$y_1^2 = \frac{12\, a^2\, y_2\, E_s}{5\, d\, E_c} \text{ for rock-concrete.} \qquad (1)$$

Also,

$E_s e_2 \frac{a^2 b}{d} = \frac{5\, b\, y_1^2\, e_2\, E_c}{16\, y_2}$ for cinder-concrete;

from which

$$y_1^2 = \frac{16\, a^2\, y_2\, E_s}{5\, d\, E_c} \text{ for cinder-concrete.} \qquad (2)$$

For the moments-of-resistance of the cross-section we have

$$Mo = P_s y_2 + \frac{2 P_c y_1}{3} = \frac{P_s}{3}(3 y_2 + 2 y_1) = \frac{F a^2 b}{3 d}(3 y_2 + 2 y_1) \qquad (3)$$

$$M^1o = P_s y_2 + \frac{2 P_c y_1}{3} = \frac{P_c}{3}(3 y_2 + 2 y_1) = \frac{5\, b\, f_c\, y_1}{24}(3 y_2 + 2 y_1) \qquad (4)$$

We also have another equation between y_1 and y_2, viz : —

$t = y_1 + y_2 + \frac{1}{4}''$ for expanded-metal construction, (5)

and

$= y_1 + y_2 + \frac{3}{4}''$ for ½-inch corrugated bar construction. (6)

For beams of equal strength in tension and compression, the following is derived : —

Here Mo becomes equal to M^1o, or

$$\frac{F a^2 b}{3 d} = \frac{5\, b\, f_c\, y_1}{24}, \text{ or } y_1 = \frac{24\, F a^2}{15\, f_c\, d} = \frac{1.6\, F a^2}{f_c\, d} \qquad (7)$$

Combining (1) and (7) and (2) and (7) we have for rock-concrete,

$y_2 = \frac{y_1^2\, 5\, d\, E_c}{12\, a^2\, E_s}$ where $d = \frac{1.6\, F a^2}{f_c\, y_1}$

$= \frac{2\, F\, E_c}{3\, f_c\, E_s} y_1$ for rock-concrete. (8)

In the same way we get

$y_2 = \frac{F\, E_c}{2 f_c\, E_s} y_1$ for cinder-concrete. (9)

Introducing these values in (4) we have

$$Mo = M^1o = \left[\frac{5\, b\, F\, E_c}{12\, E_s} + \frac{5\, b\, f_c}{12}\right] y_1^2 \text{ for rock-concrete,} \qquad (10)$$

and

$$= \left[\frac{5\, b\, F\, E_c}{16\, E_s} + \frac{5\, b\, f_c}{12}\right] y_1^2 \text{ for cinder-concrete.} \qquad (11)$$

In designing slabs for a given bending-moment, M, the following appertains : —

For this case we have $Mo = M^1o = M$, and using value of M^1o given in (10) and (11) we have

$$y_1 = \pm \sqrt{\frac{M}{\frac{5\, b\, F\, E_c}{12\, E_s} + \frac{5\, b\, f_c}{12}}} \text{ for rock-concrete,} \qquad (12)$$

and

$$= \pm \sqrt{\frac{M}{\frac{5\, b\, F\, E_c}{16\, E_s} + \frac{5\, b\, f_c}{12}}} \text{ for cinder-concrete.} \qquad (13)$$

In the following Table the values of these functions for rock

and cinder concrete and for three different kinds of metal reenforcement are given. The values for the constants are as previously given.

VALUES OF FUNCTIONS IN FORMULAS FOR CROSS-BENDING OF STEEL-CONCRETE SLABS WHICH ARE SIMPLY SUPPORTED AT THE ENDS, USING VALUES FOR CONSTANTS AS GIVEN.

M. M. SLOAN.

[To be continued.]

THE DUTY OF THE ENGINEER.[1]—I.

WE have been for some time waiting for a chance to publish this discussion since, *cæteris paribus*, the ethical and educational considerations which control the engineering and architectural professions should be nearly identical, and it is very satisfactory to find here the proof that in the main they are so identical.

THE discussion this evening is intended, I understand, to develop a somewhat informal expression of opinion on the duties of the engineer in his several professional relations. I have been asked to say a few words on his duty to himself and to his profession. A moment's consideration will show that the two are indeed inseparable. There is nothing an engineer can do in furthering the interests of his profession by which he, himself, does not become the chief gainer. The contrary is no less true. He who is remiss in discharging his duties to his profession to the measure of his ability fails to a like extent in promoting his own interests. This is, indeed, but another way of saying that every successful effort in doing something by which the profession profits adds to the professional capital of the doer, and hence redounds directly to his personal advantage. There was a time in the earlier days of engineering when its few followers had to rely upon their private note-books, containing the accumulated store of their professional knowledge, as their chief source of information. And it was natural that data gathered by the slow, laborious process of personal experience, when other means were almost wholly lacking, should have been more or less jealously guarded. In those days engineering-societies had no existence, or next to none, and engineering-literature was of the crudest kind. Just as every trade and every business had its "secrets," engineering had its mysteries. To-day such "secrets" are seldom kept, not because men have grown more altruistic, but chiefly because they recognize that it does not pay to keep them. The accumulation and diffusion of knowledge along all lines is now proceeding at such a tremendous rate that the greatest possible contribution on the part of any single individual sinks into comparative insignificance. The gain that may accrue to him by selfishly withholding the results of his personal experience and observation is apt to be as nothing compared with the professional prestige he may derive from their publication through the widest channels. It is true that there are not wanting men to-day in our profession, as in every other, who, like the sponge, absorb what comes within their narrow reach and yield it only upon pressure. Happily, such men constitute an insignificant minority. Nor can there be a doubt that they are themselves the chief sufferers of their narrow-mindedness. We can all bear ready testimony to the cheerful willingness with which engineers in general are wont to place the results of their experience at the free disposal of their colleagues, both on private and public occasions. By some this policy is carried so far that they refrain from patenting devices that show good possibilities of profitable development. While no one can reasonably condemn him who seeks to reap the largest legitimate returns from ideas that are his own, we cannot refrain from applauding the high-mindedness that prompts a contrary course. And such examples are by no means so infrequent that they must be classed as rare exceptions.

Coming now to the direct question before us — the duties of the engineer to himself and his profession — which, as I have said, are really one and the same, the answer can be put, I think, in very few words. His duty is to hold high professional ideals and to make a conscious and conscientious effort to apply them to himself, as nearly as may be, in all his professional relations. To consider in any great detail just what these ideals should be and how they are to be observed under various contingencies would be equivalent to formulating a code of professional ethics. To attempt even an outline of such a code would be alike presumptuous and unprofitable. Since engineers are human, they may be broadly classified, ethically, under two headings. First, that overwhelming majority who would not stoop to unprofessional practices under any consideration; and, second, that small but ever-present minority who strive persistently for momentary advantage without a nice regard to the means by which it is to be attained, or for the rights of others. Men whose moral sense is so warped will never be redeemed by any artificial code that may be prescribed for their professional guidance. Their natural tendencies may perhaps be somewhat curved, or at least their influence for evil partly negatived, by giving the widest publicity to their practices whenever they assume a form that plainly warrants public exposure. Our leading engineering-journals have not hesitated, in extreme instances, to assume this duty.

It has been recommended from time to time that the engineering-societies should exercise a sharp restraint upon unprofessional conduct through their power of expulsion. Experience has shown, however, that this power is rarely or never brought into play; not only because the chief offenders are apt to be beyond their pale of membership; but because it is human nature for men to condemn silently rather than accuse openly. . . .

Unlike the physician, the engineer cannot conceal downright incompetency behind an agreeable personality, nor can he count on burying his mistakes. Some years ago there appeared in one of our foremost magazines[2] two papers, in which the question "Can lawyers be honest?" was ably presented from opposite points of view. While I would yield to none in my tribute of respect to the legal profession in its best estate, it is a comforting thought that in our own profession the very suggestion of such a heading, much less a serious argument upon the question, were inconceivable. In claiming this, we need not withhold the admission that the engineer has probably less temptation to depart from normal, every-day

[1] Extracts from a paper by Edgar Marburg, read at the Engineers' Club, of Philadelphia, and published in the *Proceedings* of the same.

[2] The *North American Review*, Vol. cliii, 1891, pp. 194 and 504.

standards of rectitude than has his brother of the law. Nor does he need to defend his practices by professional traditions not always easily reconcilable with such plain standards. . . .

When we come to consider the relatively small number of engineers in independent practic , there is more ground for reasonable differences of opinion. Whatever tests of competency may be applied, however, it would seem that they should rather take the form of a searching inquiry into the professional record of the candidate than an examination. While it is easy to set an examination that will exclude incompetent men, it is exceedingly difficult to prevent the exclusion of men who are really competent. The tendency of an examination is almost unavoidably to set a premium on memory rather than general intellectual fitness; on so-called book-learning rather than on practical experience and plain common-sense.

Let us turn aside a little further to consider for a moment an interesting matter, not strictly germane to the subject. The question is not infrequently asked, Why does the profession of engineering not receive the same measure of recognition by the general public that is so freely accorded to the so-called learned professions: theology, medicine and law?

While public sentiment is doubtless growing more enlightened, one is still often amazed at the vague notions betrayed by men of good average information concerning the functions of the engineer. Even at this day a civil-engineer is not uncommonly looked upon as a surveyor who occasionally turns his hand to other duties. A college graduate, speaking of civil-engineering, once said to me, with blunt frankness, that the prospect of spending one's life looking through the small end of a telescope seemed to him singularly unattractive. I replied that I thought all men who regarded engineering in that light would doubtless share his feelings.

The mechanical-engineer is scarcely better off. The average intelligent layman looks upon him as some kind of a cross between an inventor, a machinist and a stationary-engineer; but is sorely puzzled to identify him more closely. As for the electrical-engineer, he is popularly regarded as an inventor, pure and simple, whose talents may sometimes elevate him to the so-called "wizard" class.

Quite recently I was asked by a doctor of philosophy to explain the distinction between a civil and a mechanical engineer. I could not resist the temptation to reply at first that there was none, since every mechanical-engineer was really a civil-engineer, the one being the specific, the other the generic designation. I was honest enough to add that the mechanical-engineers were somewhat inclined to object to this classification.

A highly cultivated woman whose son proposed to study engineering recently observed in my presence that she could not account for what she called her son's peculiar mechanical bent; that the male members of the family had been professional men for generations; but that her son seemed determined to become a mechanical-engineer and she supposed she would have to let him have his way. She came to this conclusion in a tone of such helpless resignation as to remind me forcibly of the luckless hen who had hatched out an ugly duckling.

These instances are believed to be fairly characteristic in showing the imperfect understanding and the inadequate appreciation of the public at large of engineering as a profession. Admitting the fact, what are the reasons? If we turn to our engineering-schools — which, by the way, are seldom counted with the professional schools — we find their average standard of admission and the prescribed length and breadth of their courses distinctly in advance of those in medicine and law; nor are they, to say the least, less difficult. Speaking generally, there is no course in a university held in more wholesome respect by the student body, or more carefully shunned by those in quest of "soft snap" courses, than those in engineering. And it may be claimed with equal confidence that there is no profession which makes more exacting demands upon its followers, and in which high honors are more difficult of attainment or, on the whole, more deservingly bestowed. Clearly the answer, whatever it may be, must be sought in other quarters.

To say that engineering as a profession is yet in its swaddling-clothes is true if the reckoning be in years. If gauged, however, by the more rational standard of achievements, we find it has attained to giant's stature. We rest our claim to professional recognition upon the fact that engineering has its basis no longer in empiricism, but in science. The justice, and, in fact, the meaning, of that claim, however patent to ourselves, can appeal but dimly to the layman. His appreciation of our work is apt to be in proportion to its outward magnitude or striking novelty. To him the building of a railway means little more than an amount of digging and filling, the laying of ties and rails, and the dumping of ballast. The construction of water-supply and sewerage systems seems to consist essentially of the opening and closing of ditches for the reception of simple pipes, whose sizes, he vaguely conjectures, are fixed somehow by experience. As for the building of pavements and ordinary roadways, or canals, dykes and levees, evidently nothing could be much easier. In short, it is impossible for him to fully grasp the idea that there is scarcely a detail of processes apparently so simple that has not been made the subject of profound scientific study and that is not undergoing constant change in the light of new inventions and discoveries.

Another reason which militates strongly against us in shaping the popular estimate of our profession lies in the fact that the overwhelming majority of engineers are employed for fixed hours at fixed salaries. The fewest number stand in direct personal relations with their clients. This circumstance is, indeed, an unfortunate one for us from more than one point-of-view.

It must be conceded, too, that the public appreciation of a profession and of its individual members stands in a not altogether remote relation to their earning capacity. To maintain a high social position on a slender income is becoming increasingly difficult and, in our larger communities, is well-nigh impossible. We cannot blind ourselves to the fact that the maximum earning-capacity of engineers is insignificant compared with that of the most successful men in other professions. When life or liberty, character or fortune is at stake, there is no haggling over fees. Retired statesmen find apparently little difficulty in speedily accumulating snug fortunes in legal practice. I need not add that engineering offers no such possibilities. In engineering a net professional income exceeding $10,000 per annum is, indeed, a very rare exception. To be sure, I am leaving out of consideration that large number of men who owe their success in kindred vocations more or less directly to their engineering training; and those to whom this training has served as a stepping-stone to salaried positions of high responsibility and trust, in lines not strictly technical. . . .

The one-sidedness of our development is due in a measure to causes normal and unavoidable. But in a larger measure the fault is one for which we are at least passively responsible. The tendency toward narrowness is apparent even among students pursuing engineering-courses. Studies not strictly technical are too often looked upon as useless and slighted accordingly. This tendency is deplorable in a double sense. Not only because the purely cultural studies occupy at best a scant place in the curriculum, but because there is probably no profession which affords less opportunity for recovering such lost ground in after-life. It is a rule, rather than an exception, that engineering-students are not able to write creditable English upon graduation. We are painfully aware, too, that this fault is not confined to the fledglings of our profession. Let me quote the testimony of the Past-President of the American Society of Civil Engineers, in his own words, as spoken at the last annual convention of that Society, in London: "For two years, during my period of holding the office of Vice-President, I was a member of the Publication Committee, and I was surprised at the manner in which some papers were presented. What I am saying now is of course not for general publication, but simply for the members of our Society. . . . If some of the papers presented to that Publication Committee by men who stand high in our profession had been presented by pupils of a high school, they would never have been permitted to receive consideration." Those of us who have served in a similar capacity can appreciate the justice of these strictures, humiliating as they are. And it is better that they should be emphasized too strongly than that they should be glossed over.

We owe it to ourselves and to our profession to recognize the danger to which I have alluded, — the danger of unsymmetric development, — and to make well-directed and persistent efforts to escape its consequences. We should seek to keep in intelligent touch with the world of men and affairs. We should strive to take a generous interest in all higher lines of human endeavor. We should try to cultivate a taste for art, an appreciation of good literature, and of all else that makes for culture and refinement. We should have a proper regard, too, for social forms and usages, by estimating them at their true worth. To despise, or to affect to despise, the amenities of life is almost as censurable as to make them the chief aim and end of one's existence.

NOTES & CLIPPINGS

RESTORING THE HALL IN THE NUREMBERG RATHHAUS. — It has been decided to restore the great hall in the Rathhaus, or City-hall, at Nuremberg. This hall, which belongs to an older part of the building, erected in 1522, is decorated with frescos by Dürer, representing the triumphal procession of the Emperor Maximilian, town musicians and minstrels, and the discomfiture of Midas; it also contains remarkable stained glass by Hirschvogel. On the central buttress is represented an execution by the guillotine, dated 1522, which shows that those terrible instruments date far back of the French Revolution. The cartoons now to be restored were already touched up and altered in the seventeenth century, and German artists are doubtful whether much will remain of Dürer's work. The German art-journals which discuss this question also note the recent discovery at Frankfort, in the Church of St. Leonard, of a curious fresco containing a large face of Christ; experts place the date some time in the thirteenth century. Also in the Church of the Holy Spirit at Nuremberg there has been brought to light, back of an old plaster partition, several curious paintings of the fifteenth century representing the death of the Virgin, a meeting of the twelve Apostles, and a colossal St. Christopher. The church dates from 1390. — *N. Y. Evening Post.*

A STRIKE THAT IS "STILL ON." — "Forty years ago, when I was a boy and living at Concord, N. H.," said a guest at a Detroit hotel the other evening, "a man built a factory for the manufacture of sleds and wheelbarrows. It was a water-power concern, and the cost was about $20,000. When the forty employés had turned out about a hundred wheelbarrows a difference of opinion arose between them and the boss. I don't exactly remember what it was, but it was stated over and over again in after years that it would have made a difference of less than a dollar a week to either side. The owner wouldn't give in, and the men stood firm, small as the matter was, and a strike took place — perhaps the first in New Hampshire. When the men walked out the owner said to them: 'Very well; you can go. Remember, however, that I'll see this factory rot to the ground before I'll give in.' They answered that they would starve before they would yield, and so the factory was locked up, and time went on. A score of attempts were made to arbitrate, but without avail. The owner grew old and gray, and the hands died or disappeared, and 5 years ago, by personal investigation I found that only the owner and one of the strikers were left alive in Concord. Knowing them both, I had a talk with them about the strike, but both were still firm. I was in Concord again a month ago. The factory was still closed and ready to tumble down, and the last of the strikers was dead. The owner was hobbling about the streets of the town on crutches, with only a few months' life left, when I said to him: 'Well, Uncle Billy, I learn that Job Sabins is dead. As he was the last of the strikers you'll open the factory again, won't you?' 'No, I won't!' he bluntly replied. 'Being as I've been a blanked fool for forty years, I'm going to keep it up the rest of my days.'" — *Detroit Free Press.*

THE ETHICS OF ELECTRICAL ENGINEERING PRACTICE. — The Council of the Institution of Electrical Engineers (England) have circulated among the clerks of some of the principal counties and boroughs the following suggestions with regard to the standard of professional etiquette which ought to be observed by, and expected from, consulting electrical-engineers: "1. No consulting-engineer should solicit employment as consulting-engineer verbally, by letter, by agent paid by commission or otherwise, or by any other means. 2. No consulting-engineer should answer advertisements for consulting-engineers. 3. No consulting-engineer should advertise for employment. 4. No consulting-engineer should pay by commission or otherwise any one who introduces clients. 5. No consulting-engineer should receive trade or other discount, or surreptitious commissions or allowances in connection with any work which he superintends. 6. A consulting-engineer who is also directly or indirectly interested in any contracting or manufacturing business should inform his client in writing what his connection is with such contractor." These are excellent rules, and it will of course be the more easy for electrical-engineers to act up to them if public bodies are informed in regard to them. — *The Builder.*

THE MUSEE FALGUIERE. — Mme. Falguière, the widow of the distinguished artist, has added one more to the numerous museums in Paris — the Musée Falguière. This is at the deceased artist's studio, No. 68 Rue d'Assas, where Falguière worked during the last years of his life; and it is well furnished with all the remaining works of the artist, both in painting and in sculpture; in the latter section will be found a complete series of sketches for all Falguière's work, from the Gambetta monument to the "Triomphe de la Révolution." — *The Athenæum.*

A SIMPLE TEST FOR SLATE. — Professor Brunner, of Lausanne, stated recently that the following method of testing slate would be found to be both simple and effective: A piece of slate measuring 7 centimetres by 3 centimetres (2.7" x 1.18") is hung by a cotton thread inside a glass vessel so as to be just above, but not touching, 100 cubic centimetres (.176 or $\frac{1}{10}$ pint) of water saturated with sulphurous acid. The vessel is closed up, and if bad the slate in a few days becomes exfoliated; if it remains compact, it will become very friable and spongy. Good slate will remain unaffected from 4 to 6 weeks, whilst superior slate has no sign of decomposition after several months. The rapid decomposition of bad slate is due to the presence of iron pyrites, carbonate of lime, and magnesia. The iron pyrites under the action of the sulphurous acid gives off sulphuric acid, which decomposes the other minerals, while the carbonate of lime under the influence of humid air and carbonic-acid gas is transformed into the soluble bicarbonate of lime. — *Stone Trades' Journal.*

A QUEER PIPE-ORGAN. — One of the queerest musical instruments that was ever built was put up in a house nearly as queer. Both were made at the instigation of Joris Karl Huysmans, a Frenchman who has been called the greatest living literary sensualist. The house was built to represent the bottom of the sea. Inside were all manner of strange seaweeds, mosses and grasses. The tinting of the walls was of pale green, with the most delicate shades of browns and pinks. Outside all the windows were great tanks of fish of nearly every known variety, for in this way he determined to keep up the illusion in which he took so much delight. But in the strange domicile that he had erected for himself there was nothing that was so in keeping with the sensualistic character of the man as his musical instrument. Charmed with a song as he was with color, it must yet mean something tangible to him. To this end he authorized the building of an immense pipe-organ, every pipe of which was connected with one central tube, which could be held in his mouth as he played. The organ was so constructed that each pipe was in communication with a butt of liqueurs, so that with each note he touched he was thrilled not alone by the sound but by a drop or two of the most choice wine. The beautiful strains of Mendelssohn's "Spring Song" or the Lohengrin "Wedding March" meant to him a double harmony; for as the beautiful chords filled his seahouse with melody he was receiving a dulcet minstrelsy of benedictine, chartreuse, crême de menthe and many other equally epicurean drinks with each wizardlike touch of the white keys. The man who conceived this weird idea has run the gamut of all human emotions to find something new and has just entered as a lay brother in a Benedictine order of monks. After living a life full of all that makes it worth living to such a man, he has given it up for a daily routine of religious observances that begin with mass at 6 o'clock, private prayers at 7, matins at 8.30, and so on through all the day, with nones, compline and vespers, and manual in all the lapses of time. This last freak seems even more eccentric than all that has gone before in his career of extravagances and eccentricities. — *Boston Transcript.*

THE MUMMIFYING PROPERTIES OF A CHURCH VAULT. — Bremen Cathedral is no less renowned than the Rathhaus, and also because of its cellar, which contains, not wine, but mummies. This cellar, known as the Bleikeller, or lead cellar, because there the lead for the roof was melted, was accidently found to have the property of preserving bodies from decay. The story of how this discovery was made speaks volumes as to the life and customs of the Bremers who lived four centuries ago. It seems that one of the workmen fell from the roof and was killed. His body being in the way of other workmen, was pushed into this cellar along with a lot of other rubbish and then forgotton, until long afterward some one found it quite mummified. And the fellow-citizens of this unfortunate workman — or was he not rather fortunate, considering the fame he had achieved, quite outrivalling that of any mere bridge-jumper? — thought the Black Death a scourge sent by God to punish them for their sins, never dreaming it was for their filth that they were being chastised. Since that time a number of bodies have been placed in the cellar. A Swedish general of the Thirty Years' War and his faithful aide-de-camp, an English duchess, and others who during their lifetime enjoyed the homage of the world, now lie there arrayed in simple loin-cloths, and any stranger who will pay the sacristan a few pfennigs may rap on their august chests or peer into the holes which vandals have knocked in the sides of two of their number. Only one sarcophagus still shields its inmate from these indignities, and that because members of his family have bestirred themselves to keep it inviolate. — *J. W. Ihlder in N. Y. Evening Post.*

THE GENEVA SCHOOL OF INDUSTRIAL ART. — The Paris *Bulletin de l'Art* gives some details of the success which has attended the work of the Geneva School of Industrial Art, an institution founded in 1875, to remedy the distress brought about by the falling off of exports in watches to the United States. Classes in enamelling and bronzework were taught by experts brought from Paris, and wood and stone carving and china-making were taught by Germans from Bavaria and Saxony, to such good purpose that the exports in all these specialties have become of large importance. Practical work goes hand-in-hand with the study of art principles, the needy student being enabled to sell the wares he makes in the school-shops. In a Government report just published the municipal authorities of Geneva testify to the value of the work done by the school, in furnishing the local factories not only with competent designers, but with a class of shop-leaders who inspire the rank and file of the workers with art enthusiasm. The course followed yearly by several hundred pupils includes drawing, modelling, iron-forging, lock-making, china-making, engraving, wood and stone carving, printing, etc. At the Paris Exhibition of 1900 the jury, in awarding a prize of honor, also offered its congratulations to the directors of the school.

The late Walter Cope. 56

NOTES AND CLIPPINGS. 56

THE annual report of the Architect of the Capitol at Washington brings forward in detail the plan already described in these pages, for extending the east part of the central portion of the Capitol to the line of the Senate and House wings, building the extension of marble, like the wings, and leaving the present sandstone walls of the central portion to form the walls of interior courts; so that the whole eastern front will be of marble. This, as is known, was the scheme advocated long ago by Dr. Walter. Mr. Woods, the present Superintendent of the Capitol, urges that Dr. Walter's plans should be faithfully carried out, and we are sure that the profession generally will support him in this recommendation. In regard to the Rotunda, Mr. Woods gives some interesting information. It seems that Dr. Walter, for a long time before his death, felt that the great height of the dome required some support in the Rotunda more visibly adequate to its work than the existing pilasters, and he proposed that columns should be set in front of the pilasters, carrying a marble cornice, and that the walls, which are now of sandstone, painted white, should be lined with marble. This would make a radical change in the appearance of the Rotunda, while the columns would encroach considerably upon its floor-space; and Mr. Woods is inclined to think that it would be most judicious, now that the Rotunda has become associated with so many important events in American history, not to make any material change in it, but to remove the paint which was put on twenty-five years ago, so as to expose the sandstone of the walls, and to change slightly the proportions of the pilasters. This treatment would restore the original solidity of effect of the stonework, without changing materially the aspect of the room.

THE plans for the restoration, or, rather, the rebuilding, of the Venetian Campanile are now complete, and the work will begin as soon as the subscriptions and appropriations reach the sum of four hundred thousand dollars, only one-half of which has yet been raised. Under the skilful direction of the Commander Boni, it has been decided to rebuild from the very foundation, increasing the area of piling to double its present dimensions, and correspondingly extending the footings of the tower. Above ground, the masonry will be laid in cement. The accounts say that puzzolana is to be used, but it seems more likely that ordinary Portland cement will be employed. The old materials are to be used over again, so far as they are uninjured, and the form of the old tower is to be retained in the new one, with the important exception that the vault over the staircase, or sloping platform which took the place of a staircase, is to be replaced by a construction of iron girders. It will be remembered that, at the time of the fall, we suggested that the thrust of this continuous vault, acting through the whole height of the tower upon the brickwork of the walls, without other resistance than that afforded by the weight of the walls themselves, might have served, if not to disrupt the masonry by slow degrees, at least to hasten the destruction of the tower when the walls had once begun to yield; and Professor Boni seems to be of the same opinion. A vault, however, constructed of brick laid in cement, abutting against a wall also of brickwork in cement, would be a very different affair from a construction built with the wretched mortar of the early mediæval period, and it seems as if the ancient vault might safely have been reproduced, in better materials, without resorting to the use of iron girders, which, however durable in a building well warmed and ventilated, and kept in repair, will be severely tried in the darkness and dampness of the Campanile stairway.

AS we have already observed, on occasion, it seems as if something might be done to improve our city architecture, which is far inferior to the rural design in which American architects are so distinguished, by the establishment of prizes, like those which are so eagerly sought after by architects in Paris and Brussels, for buildings actually executed. For a beginning, it would, perhaps, be judicious to confine competitions of the sort to structures of a particular class, and it would undoubtedly be desirable to make at least one award annually, so as to encourage competitors by multiplying their chances of success. We suppose architects in this country would agree that the sort of building which is most unsatisfactorily treated in this country, or, in fact, in any country, and which it is most desirable to improve, is the one-family city house, standing in a block with others. To a building of this kind it is very difficult to give the individual character which is the life of domestic architecture, and there are very few such houses which have any artistic charm beyond what they gain from elaborate detail; but some are to be found in all our large, closely-built cities, and the pleasure which they give is all the greater from the rarity of the examples. It is not necessary that a successful work of this sort should be costly; on the contrary, some of the best houses, at least in New York and Boston, are comparatively inexpensive structures, although, naturally, an artist can do more with abundant resources than with limited ones. The prizes themselves need be trifling. A gold, or even a silver, medal, or, possibly, both, would not involve a large annual outlay on the part of a local society of architects, and the award, perhaps by majority vote of all the members present at an annual tour of inspection of the buildings offered in competition, would attract great professional and public interest. Naturally, the only subjects considered should be those completed since the last previous award, and, as is done in Europe, the architects who have done something which they think deserving of attention should enter their buildings in competition, as horses are entered for a race. In Paris, every competing design in the annual "concours de façades" is photographed or sketched and published, much to the instruction of the public; and the award of a medal would give quite as much pleasure to the owner as to the architect. We imagine that a good many practising architects have felt that, while the travelling-scholarships, and other prizes, so generously distributed in this country among students, are of great value in their way, they have had a tendency to exalt the work of students rather beyond its deserts. That a young man should produce a design superior to that of any of his competitors in a contest for a travelling-scholarship shows capacity, but it does not indicate, as his female relatives are apt to suppose, that he has soared at once to the highest pinnacle of professional greatness. On the contrary, travelling-scholarship designs rarely, if ever, show anything beyond clever copying and a feeling for proportion, which form an excellent foundation for professional eminence, but do not constitute it. Unfortunately, the encouragement given to professional effort stops there; and the travelling-scholar, when he has developed into an accomplished and original artist, finds no one to applaud his work. It is true that he can, by degrees, build up a reputation, but the building of a professional reputation is a slow process, and depends very much, although less than is often supposed, upon accidents of family connection, temperament and other circumstances; and a trifling recognition, from time to time, by competent authority, of professional skill would have a very great effect in encouraging the younger practising architects, and in increasing

Entered at the Post-Office at Boston as second-class matter

their reputation and connection in the community. One of the topics most discussed in professional circles is the injury done to the profession and the public by the ignorant pretenders who, under the name of architects, practise every kind of misdemeanor in construction and design, if not in other matters; and it might be well to suggest that the most effective method for relegating these persons to their proper place in the eyes of the public would be for the profession to lead, not in lynching the incapable architects, but in conferring recognition and distinction on the good ones.

WE suppose that we shall be held up to public execration for saying that, devoted as we are to landscape beauty, public hygiene and forest extension, we should not grieve very much if the present scarcity of fuel in the crowded Eastern cities led to the sacrifice of a considerable portion of the shade-trees which line some of the streets of those cities. In the beautiful Western towns, or even in those no farther west than Buffalo or Cleveland, the houses, standing mostly detached, and at some distance from wide streets, or "parks," or "terraces," cannot be injured by trees on the sidewalks, and the latter are, in hot weather, gratefully shaded and sheltered by such trees; but in New York, or Boston, or the older part of Philadelphia and Baltimore, trees on the edge of the sidewalk mean gloomy shadow, instead of sunshine, in the abutting houses, dampness and mould wherever the drip from the foliage can reach, and a confined and unwholesome air in the space bounded by the trunks of the trees, their branches, the fronts of the adjacent houses and the sidewalk. The first, and one of the greatest, of American landscape-gardeners, Downing, who was as devoted and intelligent a lover of trees as any one could be, laid down the rule that no tree should be planted at a less distance from a country-house than twice its own height when fully grown, so that it might never cast an unwholesome shadow on the house; and if the shadow, even of the top of a tree, should be avoided for a country-house, open to the light and sun all around, what shall be said of the practice of planting trees of such dense foliage as poplars and maples within a few feet of the front of city houses, which are entirely dependent for sun and air upon their front and rear windows? Any person with average senses, walking through a street in New York, or Boston, or Philadelphia, or Baltimore, which is partially furnished with shade-trees, can detect at once, as he passes under the trees, an odor from the neighboring gutter, which is not perceived in the portions of the street destitute of trees, where the air circulates freely, and sunshine has a chance to do its work. If the trees stand in front of a provision store, or grocery, their effect in checking diffusion, and causing stagnation of the foul air, is still more conspicuous; and, as the people who live in the houses abutting on the street have nothing better than the street air to breathe, the trees not only deprive them of sunshine, but make the air around them much fouler than it would otherwise be. We should be far from wishing to deprive those who are obliged to pass their lives in cities of any manifestation of the beauty of nature that it is possible to give them, but sunshine, in a city house, is worth more than trees, where it is not practicable to have both; and landscape-gardeners are quite capable, if called upon, of contriving sidewalks with borders of flowering or evergreen shrubs, instead of trees. Such borders, which are already occasionally seen here, do not interfere either with light or air, and their effect is quite as rural as that of a straggling row of trees, and is much more finished and cheerful.

IT appears that an interesting work has been going on in Chicago for several years, without the knowledge of the public, in the excavation of a tunnel, fourteen miles long, under the business district of the city. This tunnel is a business undertaking simply, and is to contain a railway for the transportation of freight among the great mercantile houses, and between them and the freight-stations of the forty-two railways which enter Chicago, besides furnishing accommodation for telephone-wires, and, possibly, wires of other kinds. It is almost incredible that a tunnel of this length, varying in width from six to thirteen feet, and in height from eight to fourteen feet, could have been constructed under the most crowded part of a great city without the knowledge even of the newspaper reporters; but the tunnel is far below the surface, the depth varying from twenty-seven to sixty-five feet, so that it was unnecessary to make temporary roadways over it, and the excavated material has been taken out at night, through shafts opening in private ground, and taken away to the lake-front. The ground under Chicago is a soft clay, which was easily excavated, but it has been necessary to line it everywhere with concrete. A considerable portion of the tunnel is already in use, and many business houses have shafts opening into it, equipped with elevators, by means of which freight packages, brought by cars running on the tracks laid in the tunnel, are hoisted to the warerooms. Although an underground freight-railway of this kind seems an expensive substitute for trucks and horses, it is quite possible that it may promote economy, as well as convenience, in handling and transferring merchandise. Every one must see that the maintenance of a stable-full of horses and wagons, and of a multitude of grooms and drivers, is an important item in the cost of carrying on business, especially when, as is often the case, the wagons are driven half the time empty, or with only one small package in them; and a system by which goods arriving by rail could be at once delivered at their destination, with the minimum of handling, while those shipped could be billed through from the shipping-clerk's desk, would be of immense advantage to merchants, as well as to the public.

M. PLANAT has thought of an ingenious plan for relieving the parks, gardens and other public places of Paris from the deluge of statues and monuments with which they are already nearly choked. As he says, the street-crossings being already occupied, the gardens so filled that there is little room left for grass and flowers, and even the intercolumniations of public buildings appropriated, it is necessary to make some provision for the future monuments of the great men who may be expected to make their appearance in the world at a certain average annual rate, and whom their friends will certainly wish to commemorate. As the production of sites for statues in new gardens and parks is already very inadequate to the demand, he infers that a provision which increases with the expansion of the city, and therefore, presumably, with the production of great men, is absolutely necessary, and he finds opportunity for such a provision in the walls of the tunnels for the Metropolitan Railway, which, he suggests, might be converted into a sort of twentieth-century Campo Santo, and lined with "up-to-date" memorials of the "men of progress" who are to make that century illustrious. The passengers in the express-trains would not, perhaps, have, at first, all the time that they might wish to study the works of art that they passed on their route, but we cannot doubt that the advance of civilization will quicken the perceptions of the multitude, and a judicious disposition of the electric-lights for bringing out the salient beauties of each object would aid in producing rapid and correct impressions. M. Planat thinks that the useful might be combined with the agreeable by giving a statue of a great musician, let us say, an electric-bell to hold; while a Conservative Deputy might be immortalized in an artistic signal for stopping trains, and a machine for setting switches might take the form of an influential diplomat. In this way, as he says, the question of the proper attitude and gesture to give the subject, often a very embarrassing one for the sculptor, would be immediately solved.

THE twenty-first anniversary of the opening of the School of Architecture of Columbia University was celebrated a few days ago by a dinner at the rooms of the Society of Fine-Arts given to Professor W. R. Ware by his former and present pupils. About one hundred and fifty gentlemen were present, including many of the most distinguished members of the profession.

MR. WILLIAM ROCKEFELLER has presented to the New York Zoölogical Park a fountain which has an interesting history. It seems that a Roman antiquarian, when making a visit, some years ago, at Lake Como, discovered a fountain, sculptured in granite, which formed one of the ornaments of an old villa on the shore of the lake. It was supposed that the fountain dated from the latter part of the seventeenth century, but there were no records or other evidences of this, or of the name of the sculptor. The antiquarian bought the fountain, and removed it to Rome, where it was seen a year ago by Mr. William Baumgarten, a well-known connoisseur and dealer in New York. Mr. Baumgarten brought home a photograph of the fountain, and showed it to Mr. Rockefeller, who offered to buy it, if it could be placed in the Zoölogical Park. This was arranged with little difficulty, and the fountain is now in New York, ready to be placed in position.

NOTES ON IRON AND STEEL CONSTRUCTION.[1] — XII.

IN the above discussion and table of values the corrugated bars are supposed to have ½ inch of concrete under them, while the expanded-metal, which is laid directly upon the centring before the concrete, is placed ¼ inch from the middle of the metal to the under side of the concrete.

The reënforced concrete spread-footing is particularly adapted to the construction of a foundation supporting two columns. This is due to the fact that the footing may be made any desirable shape and can be so proportioned that the unit-pressure upon the soil will be practically uniform and the centre-of-gravity of the loads will coincide, or nearly coincide, with the centre-of-pressure from the soil beneath. The principal features in the design of such footings consist in having their plan of the correct dimensions and in providing the necessary reënforcement of metallic rods or bars.

In Figure 87 is shown a diagrammatical plan of a reënforced concrete footing supporting two columns, one at each end. In this case the loads on the columns vary greatly, for one is an exterior column supporting heavy wall loads and the other is merely an interior column carrying floor loads more or less light in comparison. It is evident, therefore, that in order that the pressure upon the soil may approach uniformity that the plan of the footing will necessarily be other than a rectangle and that it will evidently be trapezoidal, as shown in the figure. The condition to be attained is that a line passing through the centre-of-gravity of the area represented by the trapezoid shall coincide with centre-of-action of the pressure of the soil from beneath the footing.

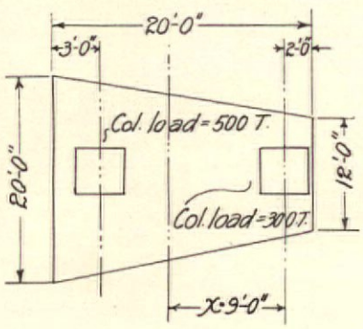

Fig. 87.

It is, therefore, first necessary to determine where this centre-of-pressure is located with respect to the two column loads. By the principal of moments it is evident, with reference to Figure 87, that the centre-of-pressure is located between the two loads so that the distance from the centre-of-pressure to either load is inversely proportional as the ratio of the respective loads on the columns. For instance, the centre-of-pressure is located at a distance from the load a expressed by the following proportion: —

$$500 : 300 :: 15 : x$$
$$500\,x = 4{,}500$$
$$x = 9 \text{ feet}$$

Hence, the trapezoidal foundation must in the plan fulfil two conditions, namely: it must have sufficient bearing-area so that the safe allowable unit-pressure on the soil is not exceeded and it must be so proportioned that its centre-of-gravity of area approaches a point 9 feet from the greatest column load.

Assume, therefore, that the allowable unit-pressure is 2.5 tons and that in consequence an area of the requisite extent must contain 800 ÷ 2.5, or 320 square feet.

The area of a trapezoid is equal to the distance between the parallel sides multiplied by one-half the sum of the length of these sides, or, as it may be expressed algebraically: —

$$A = l\frac{a+b}{2}$$

In which A equals the area, l the length, or distance, between the parallel sides, and a and b^2 equal respectively the lengths of these sides. Since the length of the footing is known from the figure to equal 20 feet, the length of one side may be assumed and the length of the other thus determined, for having the length of one side the length of the other may be expressed by

$$a = \frac{2A}{l} - b$$

so that by assuming the value of b to equal 20 feet, by substitution the value of a is found to equal

$$\frac{2 \times 320}{20} - 20, \text{ or } 12 \text{ feet},$$

and the plan of the footing becomes as designated in Figure 88.

[1] Continued from No. 1402, page 46.

It is now requisite that the area included between $c\,e\,d$ and f be analyzed to ascertain the position of the centre-of-gravity of the plan or the centre-of-pressure of the soil from beneath.

In order to find this position of central pressure, connect e and c, as shown, and determine the position of the centres-of-gravity of the two triangles, $e\,d\,c$ and $c\,e\,f$, by drawing from two

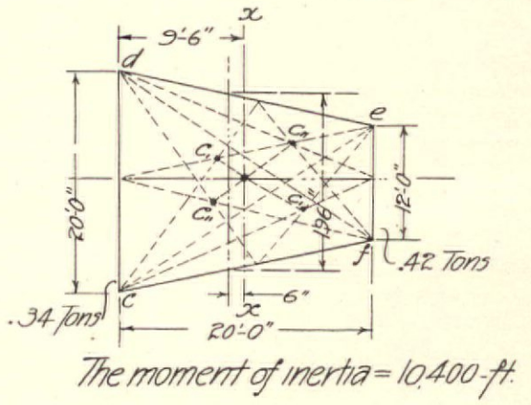

Fig. 88.

angles a line to the centre of the opposite side, and where these several lines intersect will be the required centres. Connect these centres as shown, and again divide the figure by a diagonal from d to f, dividing it into two other triangles included between the points $d\,e\,f$ and $d\,c\,f$. Find the centres-of-gravity of these triangles as before and connect them as shown. The intersection of $c_1\,c_1$ and $c_{11}\,c_{11}$ will give the required centre-of-gravity of the trapezoidal plan. In this case the centre-of-pressure from the soil is 9½ feet from the wide end of the footing and 6 inches from the centre-of-gravity of the loads.

Having this data, we may now determine the amount of steel necessary to introduce in the form of reënforcing bars to be placed on the tension side of the concrete footing, and in order to obtain the number of square inches of metal required the maximum bending-moment must be obtained.

The total load upon the footing, and consequently the resultant from the upward pressure of the soil, is equal to the sum of the column loads, or 800 tons, while the mean pressure on the soil is 2½ tons per square foot of footing area; the latter amounting to 320 square feet. The plan of the footing is shown in Figure 88 and its moment-of-inertia, or I, is by calculation equal approximately to 10,400. The distance from the line of resultant pressure of the soil measured by the area of the footing

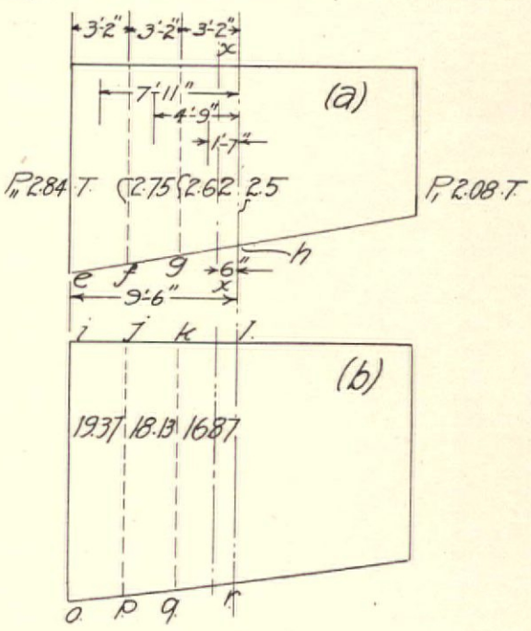

Fig. 89.

and the line representing the centre-of-pressure of the two column loads is according to the diagram 6 inches, or .5 foot. The moment produced by the resultant of the two column loads is equal to M, or $\frac{s\,I}{y}$, in which s equals the pressure on the

soil at the extreme edge of the footing, I the moment-of-inertia of the footing-area just assumed and y the distance between the lines of upward and downward pressures.

The value of M in the problem is equal to $800 \times .5 = 400$ foot-tons. The pressure variation at the edge $e\,f$ equals s, or $\frac{-400 \times 11}{10{,}400} = -.42$ tons, while the pressure variation at the edge $c\,d$ equals s, or $\frac{400 \times 9}{10{,}400} = .34$ tons. The variation in pressure may then be shown in the diagram (a) in Figure 89 when the pressure p_1 is found to equal $2.5 - .42$, or 2.08 tons, and the pressure p_{11} is likewise found to equal $2.5 + .34$, or 2.84 tons.

The maximum bending-moment on the footing is along the line $x\,x$, or the line of the resultant pressure from the soil, and it is equal to the algebraic sum of the moment of one of the column loads and the moment of the pressure from the soil beneath. The moment of the column load is equal to its amount multiplied by the distance from the axis of the column to the line $x\,x$, while the moment of the pressure from the soil opposed to the moment of the column load is equal to the amount of the pressure upon the portions $i\,j\,o\,p$, $j\,h\,p\,q$ and $h\,l\,q\,r$ of the Figure 89 at (b). The moments of these portions are equal to the product of their area and the average pressure upon them by the distance from their centres-of-gravity to the line $x\,x$. These several values may be obtained from the two diagrams (a) and (b), Figure 89, and the necessary calculations made as follows: —

Area of portions.	Average pressure.	Lever arms.	Moments.
$19.37 \times 3.16 \times$	$\frac{2.84 + 2.75}{2}$	$\times 7.91$	$\times 1{,}344.48$
$18.13 \times 3.16 \times$	$\frac{2.75 + 2.62}{2}$	$\times 4.75$	$\times 729.30$
$16.87 \times 3.16 \times$	$\frac{2.62 + 2.5}{2}$	$\times 1.58$	$\times 215.39$

The sum of the moments due to the pressure of the soil equals 2,289.17 foot-tons.

This moment in foot-tons may be reduced to 4,578,340 foot-pounds, or 54,940,080 inch-pounds.

The positive moment due the weight of the column load is equal to $500 \times 6 = 3{,}000$ foot-tons, 6,000,000 foot-pounds, or 72,000,000 inch-pounds. The difference, or algebraic sum, of these two amounts equals $72{,}000{,}000 - 54{,}940{,}080$, or 17,059,920 inch-pounds, which, if a factor of safety of 4 is desired, will be increased to $17{,}059{,}920 \times 4$, or 68,239,680 inch-pounds.

The resisting-moment of the reënforced concrete must then equal this latter amount. From Formula (10), previously given, is noted that the resisting-moment, or

$$Mo = \left[\frac{5\,b\,F\,E_c}{12\,E_s} + \frac{5\,b\,f_c}{12}\right] y_1^2$$

or, taking out the value of b,

$$Mo = \left[\frac{5\,F\,E_c}{12\,E_s} + \frac{5\,f_c}{12}\right] b\,y_1^2$$

In this case the elastic limit of the steel rods reënforcing the concrete was taken at 30,000 pounds, and the values in the formula are as follows: —

$F = 30{,}000$ pounds.
$E_c = 4{,}800{,}000$ pounds.
$E_s = 30{,}000{,}000$ pounds.
$f_c = 1{,}500$ pounds.

The value of the expression in the brackets then becomes equal to $\frac{5 \times 30{,}000 \times 4{,}800{,}000}{12 \times 30{,}000{,}000} + \frac{5 \times 1{,}500}{12}$, or 2,625, so that $Mo = 2{,}625\,b\,y_1^2$. The value of b, which is the width of the concrete-footing along the line of rupture, or the line $x\,x$ in Figure 88, is approximately equal to 196 inches. By transposition, the value of

$$y_1^2 = \frac{Mo}{2{,}625\,b}$$

and

$$y_1 = \sqrt{\frac{Mo}{2{,}625\,b}}$$

or, since Mo equals the bending-moment, which is 68,239,680, so that

$$y_1 = \sqrt{\frac{68{,}239{,}680}{2{,}625 \times 196}} \text{ or } 11.5 \text{ inches.}$$

This value is the distance from the neutral axis of the section through the footing to the centre-of-gravity of the reënforcing bars. The value of y_2 for rock-concrete according to formula (8), as previously quoted, is obtained from the expression

$$y_2 = \frac{2\,F\,E_c}{3\,f_c\,E_s}\,y_1$$

and by substitution,

$$y_2 = \frac{2 \times 30{,}000 \times 4.800{,}000}{3 \times 1{,}500 \times 30{,}000{,}000}\,11.5, \text{ or } 24.5 \text{ inches,}$$

and the entire thickness of the concrete-footing is made up of the following: —

$y_1 = 11.5$ inches.
$y_2 = 24.5$ inches.
Total..... 36 inches.

This is, however, merely the theoretical thickness and there must be added at least 3 inches at the top and bottom to allow

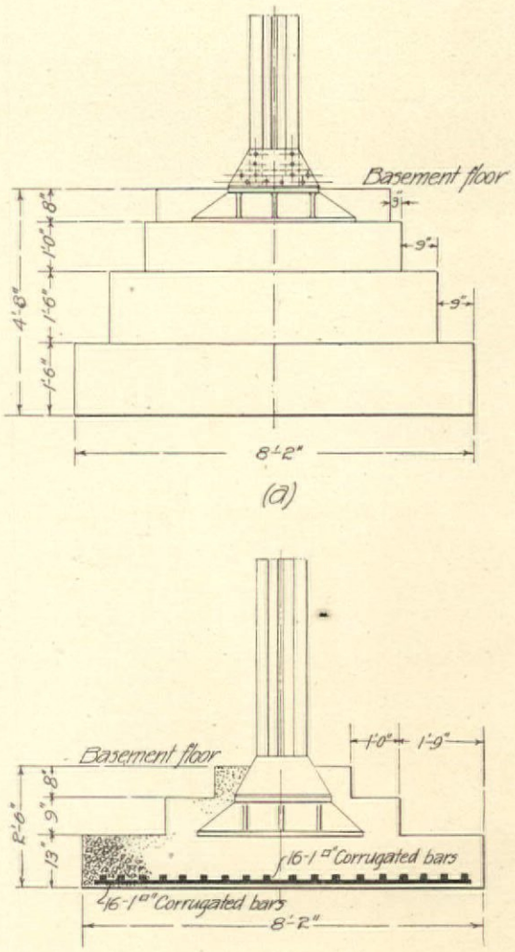

Fig. 90.

proper bedding for the reënforcing bars, and hence the entire thickness of the footing will equal 42 inches.

The last of the problem consists in determining the number of reënforcing bars required. Assuming that the square corrugated bar previously described and illustrated is used, and that a bar 1 inch square is employed with an area of about .64 square inches, the number of square inches of metal required at the section of maximum moment may be determined from the formula given in the first part of the quoted discussion. This formula is $\frac{a^2\,b}{d}$, in which a^2 equals the area of the bars in square inches, b width of the section considered in inches and d the spacing of the bars in inches. In this problem the area of the bars is taken at .8 square inches, while b obtained from Figure 88 is found equal to 196 inches and the spacing of the bars will be taken at 1.8 inches, for that distance corresponds

to the result obtained by applying formula (8) in the discussion, this formula being dependent upon the value of d as given.

Then by substitution, the total sectional-area required, or $A = \frac{.64 \times 196}{1.8}$, or 70 square inches, which would require as an equivalent the area of 109 bars.

The comparison of cost between two footings made to support an equal load upon soil of the same bearing-capacity is very clearly illustrated in Figure 90 at (*a*) and (*b*). These footings, which were designed by the Expanded-metal Fireproofing Company, of St. Louis, show upon a comparative estimate a saving of at least 20 per cent in favor of the footing with the corrugated bar system introduced instead of the all-concrete footing. The estimated cost of the construction shown at (*a*) itemized as follows: —

Excavation	11.53 cubic yards	at $.75 =	$ 8.65
Concrete	202.03 cubic feet	at .26 =	52.60
		Total.....	$61.25

While the estimate for the construction described in (*b*) is as stipulated below: —

Excavation	6.18 cubic yards	at $.75 =	$ 4.64
Concrete	.86 cubic feet	at .26 =	22.36
Extra length of column	83 pounds	at .03½ =	2.92
Corrugated bars	720 pounds	at .03 =	21.60
		Total.....	$51.52

Where a comparison of the cost has been made between steel-beam grillage footings and corrugated-bar or reënforced concrete foundations, there is found to be a saving of from 30 to 50 per cent in favor of the footing constructed of reënforced concrete. In the comparison the footings were proportioned as nearly as possible of like strength. M. M. Sloan.

[To be continued.]

THE DUTY OF THE ENGINEER. — II.

TO HIS CLIENTS OR EMPLOYERS.[1]

THE section which I discuss presents two general classes — "clients and employers" — as those from whom the engineer is expected to earn his living, and the following definitions are offered as distinguishing the classes: —

An engineer's "client" is an individual, firm, or corporation calling upon him for special or temporary service, the performance of which terminates the relations. This connection may cover a single engagement, or it may represent a series of periodic or spasmodic engagements. But in each particular case it may be assumed as a general rule that the more faithfully and energetically the engineer represents a client, the earlier his temporary engagement terminates.

An "employer" may be considered as an individual, firm, or corporation, served by an engineer under a regular compensation for a specified period, actual or implied, assurance justifying the expectation that loyal service will bring advancement, or at least continued employment. To state the distinction briefly in shop vernacular, an engineer when serving clients faithfully is "working himself out of his job," but when loyally representing employers he is "holding down his job."

The ethics which govern a true engineer are the same in each case, and he will be as faithful to the interests of clients during a temporary engagement as to those of employers under a longer term.

Accepting the definitions of client and employer, the relations of the engineer may be expected to be closer and more confidential with employers than with clients. The almost constant contact of the engineer and employer permits of mutual confidences, the abuse of which by either party is little short of criminal — confidence which permits the principal to trust the engineer and the latter to advantageously serve his employer.

Under normal conditions a client and the engineer meet often as strangers, the engineer being selected because of his reputation and the client served because of his reported financial standing. Each must, however, meet the other in confidence, and clients often place important interests at the dictum of an engineer almost unknown personally, this action being dictated by the reputation of the engineer. The profession may well be proud of such recognition, and as the reputation of the engineer is his capital, he is a fool who impairs it by acts which jeopardize his good name among men, and bring to him the unrest which follows deviation from the path of rectitude. Being treated with confidence, it is his duty to deserve such recognition by faithfully guarding the interests of either client or employer.

In his intercourse with clients and employers the engineer coöperates with all phases of the "genus homo." He may find the individual or company employing the engineer because of special knowledge, generously recognizing this knowledge, and giving him unreserved confidence, unless the engineer demonstrates incapacity or violates this faith, when a directly opposite course is justly pursued. But the work is not always so pleasant nor the duty so plain. The engineer meets with those who, failing to discriminate between power applied and power exhibited, run great risk by demonstrating brief authority, often with a result such as befell the owner of a fractious horse, who grasped the reins from the hands of a competent driver at a critical time. The driver, of course, was blamed for the loss of the horse and vehicle and for the crippling of the owner, while the owner was at fault.

There are occasions when the engineer must assert his position in opposition to a client or employer, but such assertion should be based upon his interpretation of loyalty to the interests entrusted to him, and not by wounded pride. Circumstances may arise which demand that to protect the interest of his client he must refuse to follow a procedure suggested, or to follow it under formal protest, although such action may jeopardize his position or engagement. . . .

In specifying materials or appliances, the engineer's duty to his clients or employers requires that he secure those best suited to the purpose, at least cost to his principals, and his specifications must, therefore, be drawn to invite as active competition as practicable. It is the safer policy to have an excess of bids than by restrictions to place the client or employer in the real or fancied power of bidders.

Each engineer has his preferences and is entitled to express them, but in determining "duty" he is wise who encourages active competition for work submitted to him.

The engineer who chooses his profession as a means of acquiring wealth seldom reaches that goal. If he is able to live in comfort and with but moderate anxiety for the future, he is in advance of the majority of his professional brethren. With him "a good name is rather to be chosen than great riches." There are comparatively few engineers who may be considered rich, and this limited number includes men whose accumulation has been the result of judicious investment, of legacies, or of business outside of or possibly related to engineering.

With such conditions facing the engineer, and appreciated by those with whom he associates in business, the temptation is great to augment an income by means which are inviting, and some of which at least do not suggest impropriety. Probably commissions present the most subtle of these temptations, for the engineer recognizes that members of some kindred professions depend largely upon these for revenue. This is a subject which could be discussed at length, but in determining his duty to clients he may have as a guide the statement that "no man can serve two masters."

The compensations paid to engineers do not, as a general rule, equal those received by other professions in which the cost of preparatory study and work, or of library, and the expenditure of time and energy, is less. But having entered the service of client or employer, the acceptance of commissions without their knowledge and assent places the engineer in an unsafe position; and although his earnings may be unsatisfactory, he must be true to those whose service he has entered, be this temporary or permanent.

Engineering is an exact science and it is expected to produce definite results. The client or employer submits problems which he expects the engineer to work out with the greatest practicable precision. But he is employed as a human being, and as such he is fallible. When engineers cease to err it will be after, having done their duty to God and man, they pass beyond the sphere where clients and employers exist.

In determining his duty the engineer is called upon to use the exact science upon which the foundation of his profession is laid, so as to present to client or employer the nearest approach to correct results which his education and experience, supplemented by conscientious study of the work of others, permit.

With a profession that has accomplished so much, with an appreciation of its honor, with as pronounced integrity as exists in any other profession or business, we cannot afford to have a standard or hold a position which is not the highest.

TO HIS CONTRACTORS AND EMPLOYÉS.[2]

For about thirty years of my life I was engaged as an engineer, in a practice sufficiently varied to bring me into contact with nearly all kinds of contractors. During the last ten years of my life I have been more or less a contractor, and this, I think, permits me to speak at least in the light of experience on both sides of the question.

The proper presentation of the third subdivision of this topical discussion, or "The Duty of the Engineer to his Contractors and Employés," will be difficult to accomplish in the short time at my disposal. I therefore trust that this branch of the subject will be amplified in the general discussion which will follow.

The engineer in responsible charge is generally either the author of the plans and specifications upon which the work is to be carried into effect, or he is the employed agent of such author. In either case his relations to the contractor are the same. He is assumed to be an expert in the work which he designs or directs, and the assumption warrants the inference that his knowledge of the work in all its details is as great, if not greater, as that of the contractor. This assumption is justified by the usual declarations of the specifications, making the engineer the only recognized interpreter of the meaning of the plans and specifications for the work covered by the same.

[1] Extracts from a paper by Mr. John Birkinbine, read at the Engineers' Club, of Philadelphia, and published in the *Proceedings* of the same. Continued from No. 1402, page 47.

[2] A paper by L. Y. Schermerhorn, read at the Engineers' Club, of Philadelphia, and published in the *Proceedings* of the same.

No two engineering works are more than generally alike; and specific differences will exist that make each work a special study and almost a special design. Through the preliminary study given to the development of the plans and specifications the qualified engineer should be able to acquire a fuller knowledge of the details of the work than can generally be obtained by the contractor through means and time usually at the latter's disposal, between the issue of the plans and specifications and the tender of the contractor's proposal for the work. This establishes the fact that, except in simple and routine constructive work, the designing-engineer has a better opportunity than the contractor to thoroughly familiarize himself with all the difficulties and uncertainties of the work. Therefore in this respect the designing-engineer enjoys an advantage over the contractor which it is his duty to recognize, through the plans and specifications, by fairly placing before the contractor full information upon points which otherwise would escape the contractor's knowledge. His duty is something more than to vaguely suggest possible difficulties and requirements, and then create for himself a refuge, by ignoring all responsibility for lack of reliable data, by providing that the information upon essential points in the specifications is not guaranteed, and that the contractor through his personal knowledge and examination will be assumed as having full and correct information upon all matters involved in the work, even though the engineer may have suppressed a part of his information. It goes without saying that the contractor has, in the end, to assume such responsibilities; but it should be based as far as possible upon a full knowledge and frank avowal of all that the engineer knows of the work.

This duty of the engineer is a delicate one, and the personal equation of the individual will largely determine his action in the matter. Should his personal views be interfered with by those of his employer, then the engineer must determine for himself how far the ethics of his profession and his duties to himself and his fellow-man will rightly permit his judgment to be overruled by his superiors. To intentionally suppress important information which would be difficult or impossible for the contractor to obtain is at once a crime against the public and an error which is more than likely to assert itself unfavorably in the work with which it is connected. Dishonesty in the administration of work will surely result in dishonest execution, and this in turn may lead to disaster, involving both property and human life.

There never was an alleged wise saw that had less foundation in fact than that which states that "competition is the life of trade." If the word *death* were substituted for *life*, the statement would be nearer the truth. In nearly all callings, intelligence, ability, and its proper accompaniment, reputation, count for much in winning business success. In the other professions we never hear of assignments made on the basis of competition; and yet the engineer is too often forced to carry his plans into effect under a system of unqualified competition that is at once destructive of good results and unfair to the contractor who will only do his work in a proper manner, and whose prices are based upon such a method of work as will ensure satifactory results to the engineer and to those for whom the work is done.

Open, unqualified competition, without reservation as to awards thereunder, is an invitation and an encouragement to the incapable, unwise and dishonest contractor to enter into competition with the contractor who believes that capacity, experience and honesty are essential elements both to his success and to the success of the work that is to be carried into execution. When incapacity, inexperience and dishonesty are joined with political pull and favoritism, the premium placed upon the dishonest execution of work is such as to forbid competition on the part of contractors who do not adopt such methods.

The duty of the engineer under such adverse conditions is plain, for he must either be in a position to demand and secure the proper execution of the work entrusted to his charge, or he must retire himself from a responsibility which is almost sure to result in the dishonest execution of his plans and designs. The engineer owes at once a duty to his employers and the public, through which, by all legitimate means, the incapable and dishonest contractor is excluded from the possibility of competing for work to be done under the engineer's direction; and if it is impracticable to accomplish such an end by not allowing this class of contractors to bid upon work, the power and authority should be inherent in the specifications to permit the exercise of a discrimination which can be used to prohibit his securing the work.

The undesirability of unqualified competition is well recognized through the manner in which individuals and many large corporations invite proposals for required work or materials; viz, by placing their proposals only in the hands of such parties as are known to be capable, experienced and honest. In the main, our cities and the general Government are the only parties who do not adopt ordinary business methods in selecting their contractors, and where the only criterion is the lowest prices offered for the work to be done or the material to be furnished.

With the United States Government this method of unrestricted competition is carried to the extreme, upon the theory that the bidder's or contractor's bond establishes the responsibility of the bidder or the contractor; and more attention is given to very exact compliance with instructions as to the seals and notarial attestations upon the bonds than is given to the ascertainment of the fact whether or not the bonds have any real financial value. As a result of this method the Government has constantly upon its public works failing and defaulting bidders and contractors, against whom legal action is seldom taken toward the enforcement of the penalties provided in the contract. While there may be a theoretic value in the moral effect of bonds and penalties named, such effect is lost upon the irresponsible and dishonest contractor, who through a long experience has gained a valuable knowledge of shrewd methods and tricks by which he can escape their enforcement, and upon which he fully counts when he enters into contract.

The engineer who is brought into administrative contact with the irresponsible and dishonest contractor will find himself quickly engaged in a conflict, whereby the efforts of the engineer to enforce the proper performance of the work will be met by every effort on the part of such a contractor to cheapen the work, or else to prepare the way for a successful escape from the penalties of his bond, if the work is not carried to satisfactory completion. The engineer who has gone through such experiences emerges from the conflict always a disappointed, but generally a wiser, man.

From an experience of many years the speaker has been brought to feel that many engineers are inclined to hold a responsible and conscientious contractor to a more rigid enforcement, even of non-essentials, than an incapable and dishonest contractor to matters essential to the proper performance of the work. The reason for this is that it is easier to secure exact compliance from the former than even approximate compliance from the latter; but the question arises whether the engineer has a moral or professional right to attempt to move in such matters along the line of least resistance.

Considering the engineer as the direct agent of the parties who are to pay for the work done, it may not seem unnatural for the engineer to yield to the temptation of seeking the accomplishment of his work at the least possible cost to his employer, regardless of what he knows to be the real intrinsic value of the work. Adopting this view, some engineers encourage unqualified competition to its extreme, and attempt to reduce each letting of work to the methods and principles which surround the bargain-counter.

Every work is worth its absolute cost as carried into proper execution under wise, economic and efficient administration, plus a reasonable profit to the contractor. The engineer who seeks to accomplish his work at less than what he knows to be its true value violates the fundamental principles of sound business, and thereby lends himself to the perpetration of a fraud upon the public, and an injustice to his employer and his contractor.

The engineer in responsible charge of work cannot give his unqualified time and attention to the details as they are carried out in the field; he therefore must delegate this duty of immediate supervision to his assistants or inspectors. Frequently this duty falls into more or less inexperienced hands, with the responsible engineer often far removed from the work, or else not easily accessible. The value is very great to the contractor and to the work of having at all times immediately accessible a representative of the engineer who, through training and experience, is qualified in an emergency to promptly act for his superior. Wisely as plans and specifications may be prepared, they are nevertheless not inspired and inerrant, and often the unexpected and unprovided-for contingency will arise that demands correct judgment and instant action, based on experience, and a large amount of level-headedness and common-sense. If at such times the representative of the engineer does not possess these qualities, both the work and the contractor will be sufferers; and these are injuries the engineer has no moral or professional right to inflict on either the work or the contractor.

Carefully as plans and specifications may be prepared for works involving much detail, they can seldom provide for every variation from the normal which may occur; and when such variations do occur, the representative of the engineer who reads his specifications as though they were his Bible, expecting to find therein provision for all things, will surely be disappointed, and the work and the contractor will as surely suffer through the inspector's ignorance and misguided faith. No more unsatisfactory representative of the engineer can be found than he who is unable to call to his aid experience and common-sense in interpreting the true spirit and intention of the plans and specifications.

It follows from these conditions that among the duties which an engineer owes to his contractor is that of being represented upon the work by an assistant who has other qualifications than those of being related to somebody, or one who votes on the right side, and who may therefore enjoy the favor of the district politician. An assistant or an inspector whose employment is based upon qualifications other than his fitness for the work, and whose tenure of office is not measured only by his capacity and known honesty, is an injustice to the contractor, and a standing menace to the work upon which he is employed.

The position which the engineer holds as to his employer and his contractor is without its parallel in the other professions, and his duties which arise thereunder to these parties are at once responsible and delicate. The engineer is quite generally made the only authoritative interpreter of the true intent and meaning of the plans and specifications; and the specifications more or less definitely provide that he shall determine every question, difference or doubt in relation to and arising from the work undertaken, and shall decide every question which may arise relative to the execution of the contract on the part of the contractor; that his estimates should be held as final; and that his specific conclusions and decisions shall be beyond appeal.

These broad and conclusive powers would suggest that the engineer

is an arbitrator between his principal and the contractor, and clothed with the fullest power of decision and action; and yet the analogy is not complete. An arbitrator should be a disinterested party, and such the engineer is not. An arbitrator should not be under the pay or influence of either party; the engineer is manifestly under both from his principal. An arbitrator should have no interest in the questions he is to decide; the engineer is called upon to support his interpretations of his own plans and words, and to justify his estimates and conclusions generally. The position and its duties are anomalous, and a legal authority, commenting on the situation, said: "Under these conditions the contractor's rights depend upon his good luck in having his work under the supervision of an honest and conscientious engineer; and that the employer's obligations to pay or to perform depend upon his approval and the behavior of his engineer"; and that under such conditions "the courts undertake to guarantee the contractor that the employer or his engineer shall not capriciously nor unreasonably exercise his power to defeat the contract, or deny the contractor his just and reasonable compensation." No engineer has a right to force a reasonable contractor to carry into the courts the determination of questions that arise between them; for most contractors know that after resort to such an expedient their subsequent lot would not be a happy one; and that their position thereafter would be sadly prejudiced.

The apparent arbitrary power given to the engineer in the usual specifications and engineering contract, and which are probably generally conceded by the contractor, have their limitations in practice. Numerous decisions of the courts stamp with disapproval contract stipulations which tend to bind parties, before the occurrence of an event, to the arbitrary reference of matters arising from such events to an arbitrator without judicial functions. Neither have the courts regarded with favor the attempts of parties to oust their jurisdiction through unqualified agreements for arbitration. It should not be forgotten that all agreements for arbitration are revocable by either party at any time before the decision has been rendered by the arbitrator. This further indicates the attitude of the law toward arbitration. A very recent case decided by Judge Lawrence, of the New York Supreme Court, well illustrates this subject. Under a contract it was provided that, to prevent all disputes and litigations, it was agreed between the parties to the contract that the engineer should determine all questions of difference, and was to fix the amount and quality of the work to be done; and that the findings, estimates and decisions of the engineer were to be final and conclusive. The Court held that this provision in the contract was clearly to make the engineer the absolute and final arbiter as to all questions arising between the parties; that the provision in question, if made operative, would oust the courts of jurisdiction; and therefore it was decided as being void on the ground of being adverse to public policy. This decision is in harmony with well-established judicial maxims and conclusions, and is supported by a long line of decisions.

Through the very powers which are, of necessity, given to the engineer, he owes a duty to his contractor and to his employés to treat all situations and conditions which may arise with judicial fairness; and while entitled to insist upon the full and proper carrying into effect of the work undertaken, he should not forget that his contractor holds rights which honesty and justice demand shall receive fair recognition. To fully meet the requirements of such a situation and its duties bespeaks for the engineer the admirable traits which we believe are an accompaniment of the profession under its best development.

Contrast such a view of the duties of an engineer to his contractor or his employés with the following, as set forth in a text-book intended for the use of the profession: "The engineer is in the interests of the proprietor, and receives his compensation from him. . . . He is not required nor expected to watch the contractor's business, nor to promote his interests, and any attempt to do so might render his position untenable, change the relations of the parties, and render the stipulation of his choice invalid." Again the same writer states: "The engineer owes no duties to the contractor except what he can demand by the terms of his contracts; he is under no obligations to protect his interests or assist him in his affairs." I should be sorry indeed to believe that such a doctrine could be held by the engineer who dignifies his profession and its duties, and who believes that these duties have their foundation in honesty, intelligence and justice.

THE PHILADELPHIA CITY-HALL.

ALONG with the announcement that after thirty-one years of work one of the largest buildings in America is nearing completion comes another to the effect that the big pile is so overcrowded that its 4,500 tenants are beginning to call for the addition of another story, says the New York *Sun*. This despite the fact that the structure, Philadelphia's City-hall, has 682 rooms with a total floor-space of 118 acres and has cost about $25,000,000.

George G. Pierie, Chief of the Bureau of City Property, and John M. Bunker, the building's superintendent, are being bothered with another complaint. They are told continually that the building's twenty-two elevators cannot accommodate the thousands of persons who enter the hall daily.

A recent report, in endeavoring to explain this expenditure, reveals some interesting facts. It states that $317,000 has been paid to the architect and his assistants in salaries since 1871, when the building was begun: $351,490 for paint and painting; $5,500,000 for 1,464,000 cubic yards of marble for marblework; $4,000,000 for fitting-up rooms; $1,343,000 for watchmen and cleaners; $736,000 for electric-installation; and so on.

The installation of electricity furnished an interesting incident in the hall's history. When the walls were erected electric-lighting was unheard of, but when its usefulness was demonstrated the now extinct Public Buildings Commission ordered electric-equipment.

The electricians had to chisel through the stone walls for the wires at an expense of thousands of dollars, and it took them the better part of five years of steady work to wire the building. Now, however, the hall has a plant capable of furnishing all the light a city of 30,000 or 40,000 inhabitants could possibly use.

The dynamo-room is one of fifty-nine in the building's basement, which runs not only under the hall, but the plaza in the centre as well. These basement-rooms teem with surprises. For one thing there is a sand-bed filter with a daily capacity of 1,000,000 gallons of water, and the employés and thousands of strangers who daily tread the corridors manage practically to consume this amount. Thousands of gallons are carried to their homes by the employés, for the water furnished the Philadelphia householder is about the worst on earth and will be until the city gets its big filter-beds in working order.

Like the lowest portion, the highest part of the building, the tower, is an interesting and curious place. It contains the largest stone in the building, a block of granite weighing 30 tons. It is 12 feet wide, 23 feet long, and 8 inches thick.

The tower's walls are 22 feet thick.

The second highest elevator in the world is in the tower. It runs from the seventh floor, 138 feet above ground, to the base of the Penn statue, an upward course of 372 feet 9 inches. The air-cushions alone cost $25,000. One of the 400 telephones in the building is located in the tower, at the base of the statue.

Then there is the great clock, and the little clock that governs it. Compressed air is the motive-power.

The dials of the great clock are 361 feet above the earth, and the diameter of each is 26 feet. The long minute and hour hands are 12 and 15 feet, respectively, and their weights 225 and 175 pounds. The weight of the dial-frames, with glass, is 5½ tons, and the total weight of the clock is 50 tons.

The little, or master, clock, the clock that really runs, is 143 feet below the great clock by which the city and country folks for miles around regulate their watches. Two years were spent in building it, and its mechanism is as delicate as that of the finest watch.

It rests in a metallic case on a platform built into a wall so no vibration can affect it. Quite unlike the big clock, which in four years collected 3 tons of dirt, the case keeps it free from dust.

Once every minute this clock, which is regulated from Washington, opens the valves which admit compressed air to the tubes connected with the gears. The air moves the hands of the clock up in the tower, which, after all, is just a dummy-clock, for it has only four faces and lets the little clock down below do all the actual work.

Another peculiar thing about the tower is that in the course of a day contraction and expansion, due to the sun's rays, make it lean ¾ inch out of plumb. This peculiarity has been determined by means of a tub of molasses placed far up in the tower, the surface of the molasses varying ¾ inch, according to the lean of the tower.

Then, too, the tower is an insatiable and inveterate destroyer of the birds of the air. The ring of sixteen powerful arc-lights that glow at the base of Penn's statue blinds the birds so that they fly against the tower, are killed and fall to the roofs below. One of the hall's employés has a collection of over a thousand birds that were killed in this manner.

The statue of William Penn that caps the tower weighs 53,348 pounds and is 37 feet in height. The hat is 9 feet in diameter, the rim 23 feet in circumference, the buttons on the coat are 6 inches in diameter, and the coat-cuffs are 3 feet long.

Penn himself has a nose 13 inches long; eyes 12 inches in length and 4 wide; a mouth 14 inches from corner to corner; hair 4 feet long; a face of 3 feet 3 inches from hat to chin; a waist 24 feet; fingers 2 feet 6 inches long; nails 3 inches long; legs 10 feet from ankle to knee.

Between tower and basement are many queer things. The largest room measures 58′ x 71′ and has a floor-area of 4,118 square feet. This is the Common Council chamber, and two three-story houses, Philadelphia style, could easily be placed in it.

Thirteen of the rooms occupied by the city-solicitor's department are furnished in steel. The only things inflammable in them are the wooden tops of a few tables and a half-dozen carpets.

Desks are of steel, as well as doors, window-frames and thousands of fireproof boxes for municipal documents. Four hundred and seventy-seven tons of steel were used in fitting up these rooms and it took seventeen months to do the work.

Another room entirely of steel, except the table-tops, is the Law Association Library, where 38,000 volumes are kept. This library, the second largest of the kind in America, has among its many other treasures one of the two existing sets of transcripts of the complete records of the United States Supreme Court.

The seating-capacity of the seventeen court-rooms is about 8,500. In addition to these 8,500 chairs, 5,000 chairs are scattered among the various offices. Every room has a clock, and each room contains on an average three roll-top desks, making about 2,000 of these in use in the building.

Two chandeliers cost $4,800 each. They are gold-plated. They

hang in what are known as the conversation-rooms, in decorating which tens of thousands of dollars have been spent. These rooms are really reception-rooms for the use of the Mayor and Councils.

The biggest stone column is 24½ feet high and 2 feet 8 inches in diameter. It weighs 14 tons and is of one piece. It and nearly all the stone used in the building came from a single quarry in Massachusetts.

There are nearly three miles of main corridors and one-half that distance of branches.

The five guides declare that, on an average, 600 persons, who have no object in view other than that of sight-seeing, are daily shown through the building. This makes a total of 150,000 yearly.

Bridal couples are in evidence by thousands. When the courts are in session the corridors are so blocked that one can scarcely push his way through.

Twenty-two persons have met death while working on the City-hall. All have been killed by falls. One man recently fell from the brim of Penn's hat. Another was killed by a fall of 12 feet.

THE LATE WALTER COPE.

PHILADELPHIA, PA., Nov. 8, 1902.

TO THE EDITORS OF THE AMERICAN ARCHITECT: —

Dear Sirs,— At a special meeting of the Philadelphia Chapter of the American Institute of Architects, called to take action upon the death of Walter Cope, the enclosed resolutions were adopted.

Trusting that you will find an opportunity of publishing the same, I am,

Very truly yours,
ARTHUR H. BROCKIE, *Secretary.*

Resolved, that in the overwhelming sadness which the sudden death of our friend and associate Walter Cope has cast about us, we still rejoice in the beauty of his life and his labors, which leave behind them so precious a memory and so stimulating an example. Deeply skilled in his art, there were brought to him from far and near problems of ever-increasing difficulty and importance. He bore joyously the burden of these many tasks, and stood before us steadfast in the discharge of duty, untiring in the pursuit of excellence and beauty, firm in upholding a noble standard of conduct. And yet it is not his work as an architect, distinguished as it is by volume and quality, that leaves with his companions the deepest impression of him, but rather his constant sincerity, his limpid truthfulness, his spontaneity and frankness, his joy in art, his splendid scorn of wrong.

Resolved, that in the death of Walter Cope, the architects of America have lost one of the ablest of their number, and that we his immediate associates mourn him, not alone as a fellow-artist, but as a friend tried in many ways and true in all.

NOTES AND CLIPPINGS

TELEPHERAGE MAILS IN ITALY. — Tests are being made upon a telepherage-system of postal-communication in Naples which seems to be simple and satisfactory. The plant consists of a small aërial railway whose track is made of steel wires, supported at the height of 45 feet on poles 300 feet apart. Small motor-cars run suspended to these wires, and are fed with electric current. The motors are so designed as to communicate to the car a speed of 400 kilometres (250 miles) an hour. With a speed of this kind, all the Italian post-offices would be in communication on a very rapid schedule. In Rome a main post-office is to be installed in conjunction with eight or ten sub-stations, each sub-station being in a tower 75 feet high, provided with a mailing-box at the bottom. All letters mailed are automatically stamped with indications of the month, day, hour, and minute at which the letter was mailed. The letter is then conveyed to the top of the tower, where a special employé is in charge of putting all the mail in the small motor-car, which is then sent to the general post-office. Thence the mail is then forwarded to the different cities of Italy in less than two hours. Each steel wire of the line is designed for carrying a weight of two tons. The motor-cars for letters weigh 75 pounds, and the cars for printed-matters are able to carry 2,000 newspapers. With this scheme, it will be possible to read at 10 o'clock in Milan all newspapers printed at 8 o'clock in Rome. The cost of installation of this kind of plant reaches 3,000 lires ($600) per kilometre, or about $950 per mile. — *N. Y. Evening Post.*

USE OF WHITE-LEAD IN FRANCE. — The Minister of Commerce and Industry has submitted for signature by the President of the French Republic the following decree regulating the use of white-lead for house-painting, accompanied by a report stating that the text has been approved by the Consultative Committee of Arts and Manufactures and also by the Council of State, while the last-named body has for the present declined to sanction total interdiction of the deleterious substance in question. Article 1. In painting shops, white-lead must only be used in the state of paste. Art. 2. The direct use by hand of products with white-lead base is forbidden in house-painting works. Art. 3. The dry scraping and rubbing with pumice-stone of white-lead paint are forbidden. Art. 4. For wet scraping and rubbing with pumice-stone, and generally for all work of white-lead painting, the masters must provide overalls to be used exclusively for the work, and must enjoin their use on the men, having these overalls frequently washed and kept in good condition. All that is necessary to ensure cleanliness must be provided for the men at the spot where the work is carried on. The tools and appliances are to be kept in a good state of cleanliness, but without dry scraping. Art. 5. The masters must have the text of the present decree posted up in the localities where men are taken on and paid. Art. 6. The Minister of Commerce, Industry, Posts and Telegraphs is charged with the execution of the present decree, which will be inserted in the *Bulletin des Lois* and the *Journal Officiel* of the French Republic. — *Journal of the Society of Arts.*

MARTINMAS.—Apropos of Martinmas, Zitella Cocke writes in the Boston *Transcript:* "That St. Martin has supplanted Bacchus in Italy and other parts of the Old World is no doubt true. The god of the grapes and the vintage has been compelled to yield to the humble and amiable saint. Spain is eminently enthusiastic in her celebration of Martinmas, and surely in the northern and mountainous region of this country, St. Martin's summer is as beautiful as poet or artist could dream. Her finest bridge, which is, in fact, one of the most superb structures of the kind in the world, spanning the famous river Tagus, near Toledo, bears the name of San Martin, and it was in the soft, sweet time of Martinmastide that the wife of the architect who designed the bridge stole away from her home at midnight and burned it, because her husband had revealed the secret to her, that upon the very day of its completion he had detected a fault in the construction which rendered the whole bridge unsound, thereby costing him the favor of the King who had so generously entrusted the undertaking to his skill. His despair forbade all hope of remedy, but the wife, with a woman's intuition, knew what to do, and she did it. Inasmuch as the bridge, through this untimely accident, needed rebuilding, the commission was given, of course, to the same architect, who did not make a second mistake. It was rumored that the King heard the cause of the 'accident,' and, with a royal guffaw, exclaimed: 'Capital wife, by St. Martin, a capital wife. I wish every man in my kingdom had so good a one!'"

GAS AS HEAT, LIGHT AND POWER.— The use of gas as a fuel and source of power has made wonderful strides during the last decade, and present indications point to a still more marked advancement in the methods of production and systems of lighting, heating and power supply. The systems of incandescent gas-lighting, so prevalent and popular at the present time, depend for their efficiency wholly upon the heating-power of gas, rather than on its luminosity. Water-gas or producer-gas will undoubtedly be the future heating and lighting agencies, and along the lines of their production will be directed most of the forces of investigation and improvement. The future trend of gas-production will probably be in favor of generator rather than retort gases, which ought to result in purer gases; *i. e.*, gas of a fairly constant chemical composition. — *Mines and Minerals.*

THE SHORTENING OF EYESIGHT IN WINTER. — Experiments in German schools have shown that in October pupils can on the average see letters of a given size a yard farther away than at the end of the winter months. — *Exchange.*

NOTES AND CLIPPINGS. 63

WASHINGTON UNIVERSITY, in St. Louis, opens this year its regular course in Architecture, which has been for some time in preparation. The course occupies four years, and is modelled upon that of the other great architectural schools in this country, resembling most, perhaps, that of the Massachusetts Institute of Technology. The Professor in charge of the Department of Architecture is Mr. Frederick M. Mann, who is well known in the profession, and will undoubtedly be a sympathetic and successful teacher. In addition to Professor Mann, Messrs. William B. Ittner, James P. Jamieson, E. L. Masqueray, J. L. Mauran and Thomas C. Young constitute a special committee, which has in charge the management of a Travelling Scholarship, offered to draughtsmen and young architects, under the auspices of the University. By a commendable innovation in the ordinary routine of travelling scholarships, candidates are required to spend the whole winter in work upon six rendered problems, and six sketch problems, after which they must pass a satisfactory examination in construction, architectural history and elementary French. Immediately after this examination, the award of the scholarship will be made, by a jury of three prominent architects residing outside the State of Missouri, three rendered problems and two sketch problems being selected, to be submitted by each candidate. In order to secure uniformity of conditions, as well as to utilize the work of the candidates as far as possible for the benefit of all, it is required that all the competing drawings shall be made in the rooms of the Department of Architecture, which are kept open until ten o'clock every evening for this purpose.

DR. LEDERLE, the President of the New York Board of Health, is rapidly making a name for himself by his energy in studying the public good in his own province. Recently, he determined to see, if possible, how far, and in what way, leakage of gas into the cellars of houses through defective pipes affected the health of the occupants of such houses. In the course of his investigations, his attention was directed to a gas main, two and one-half inches in diameter, in a single length of which, fifteen feet long, there were twenty holes. Naturally, the gas escapes in enormous quantities from such mains as this, and a large part of it finds its way, usually, into the neighboring cellars, the walls of which are often as permeable as the pavement over the pipes. Another way in which gas is said to be brought into buildings is through pneumatic tubes, which are often placed in the same trench, or conduit, with gas mains, and draw in gas from the leaks in the latter, to discharge it into the rooms served by the tubes. As pneumatic tubes, to be operated successfully, must be at least nearly airtight, it is difficult to see how gas could be drawn into them except from a source practically saturated; and the infection of cellars around such a spot would be likely to be much more serious than that carried through the pneumatic tubes. Dr. Lederle is said to be trying to trace an apparent connection between the infection of houses from leaky gas mains, and the occurrence of typhoid fever in the same houses. Of course, no one would expect to find the typhoid bacillus in gas, but the typhoid germ does not usually propagate itself in persons in full health and vigor, and it is very possible that the breathing of air contaminated with small quantities of gas may produce such a depression of vitality as to expose the system to bacterial influences.

THE so-called "Drainage Canal" case, in which the State of Missouri is plaintiff, and the State of Illinois defendant, has come up before the Supreme Court of the United States, and, by agreement, the plaintiff is to have four months to prepare and present its evidence, and the defendant is then to have four months to present its reply. After this, each side is to have fifteen days for rebuttal of the evidence presented by the other. The attorneys for the State of Illinois had petitioned the Court to dismiss the case, on the ground that Missouri had neglected to prosecute its complaint; but it appeared that the Missouri authorities, instead of neglecting the matter, had spent a large amount of money in having analyses made of the water of the Mississippi below the inlet of the drainage canal, as a preparation for presenting its case, and the motion to dismiss it was therefore withdrawn. The testimony offered by Missouri, when the case is formally opened, will be of the greatest importance and interest to the whole civilized world. For many years, engineers and sanitarians have been unable to agree as to whether sewage can be discharged into a river without danger to persons who take water for drinking from the same river at any distance below. Even after the theory that sewage was immediately rendered innocuous by dilution with river water had been abandoned, the great majority of engineers believed that if the sewage was diluted with a certain proportion of water, and then exposed to the air during a flow of a certain number of miles, it was so changed as to lose its noxious properties. As time went on, various mishaps began to cast doubt upon this theory, and, ten or twelve years ago, one of the most eminent of English sanitarians declared that no river was long enough to purify sewage. The terrible cholera epidemic at Hamburg, which was traced directly to sewage in the river Elbe, cast additional doubt upon the river purification theory; and the tendency of science now is to consider that, while analysis may show a rapid decrease of albuminoid ammonia in flowing river water, it does not follow that specific germs are quickly destroyed, or that some of them may not preserve their vitality for a very long time in such water. Positive evidence on this point has not, however, been made public, and the investigations of the experts for the State of Missouri, corrected, if necessary, by those of the State of Illinois, will afford the first important contribution to the knowledge of the subject.

DR. AMBROSETTI, of Argentina, made an important contribution to the recent Congress of Americanists, in a paper describing the remains which still exist in Argentina of a race which seems to have resembled very closely the Pueblo Indians of Arizona and New Mexico. While, however, a remnant of the Pueblo Indians of North America still maintains its tribal organization and its habits of life, the Calchaquis, as the Indians of the corresponding race in the South are called, have totally disappeared, the few who escaped the weapons of the Spanish conquerors having been taken to Buenos Ayres, in the middle of the seventeenth century, where they intermarried with other natives, until their identity was lost. Before the Spanish invasion they seem to have formed a populous and powerful community, living in collective habitations, or pueblos, traces of which are scattered over the plains and mountains through a tract some nine hundred miles long. Although the Spanish soldiers were experts in the art of plundering the poor Indians whom they conquered, they overlooked some of the objects contained in the Calchaquis' pueblos, and Dr. Ambrosetti has collected a large number of gold and silver ornaments, beads of turquoise and shell, weapons of bronze and pottery, decorated with the figures of serpents which play such a singular part in the art of Central America and Egypt, as well as of South America. Among the villages Dr. Ambrosetti found many groups of stones, standing vertically, each a little higher than a man, and carved with a rude human face. These groups are surrounded by rings of stone, and recall the so-called Druidical monuments of Europe. In general, the Calchaquis seem to have been inferior to the people of the

Entered at the Post-Office at Boston as second-class matter

Incas in wealth and intelligence, and appear to have formed a community apart from them, living an agricultural life, something like that of the Northern Pueblo Indians, but adopting a scientific system of irrigation which would be beyond the intelligence of the latter. That they were on terms of hostility with their neighbors, even long before the Spanish invasion, is indicated by the care with which the mountain passes leading to their territory were fortified; and it seems not improbable that they may have represented the aboriginal inhabitants of Argentina, who had retreated to the mountains before an invasion of the Incas, and maintained themselves there until the oppressors and oppressed alike were overpowered by the still stronger Spaniards.

ONE of the most sanguinary battles ever fought in Europe is recalled by the dedication of a large and beautiful church at the foot of the Shipka Pass, in Bulgaria. In this pass, the Pass of the Wild Rose, to translate into English its poetical name, was fought, in August, 1877, a battle, which lasted five days, between the Turkish and Russian armies. The soldiers on both sides fought with a heroism which will make their names immortal, and it was not until eighty thousand men had fallen that the Turks gave way, opening the route through which the victorious Russians marched, later, to Constantinople. With characteristic piety, the Russians, after the close of the war, prepared to commemorate the struggle by the erection of a church, which has been carried out by the Russian Government, and presented to the Principality of Bulgaria.

THE Academy of Fine-Arts in Berlin holds every third year a competition of a peculiar kind. Only Prussian architects are admitted to it, and candidates must not have passed their thirty-second year. Persons qualified under these conditions are required to submit plans, elevations, perspective drawings, sections and photographs of some building entirely carried out from their designs and under their direction. These documents are inspected by a jury, which awards to the author of the best a prize, consisting of the sum of thirty-three hundred marks, or about eight hundred dollars, which the winner is obliged to spend in a year's travel and study, at his discretion, the only restriction being that, unless he is familiar with Italy, he must spend a part of his time in that country. As the prize is awarded only once in three years, it does not constitute a very heavy drain upon the resources of the Academy, while it affords a valuable stimulus to young architects to study their early work to the utmost, in the hope of winning such a distinction.

ONE of the English magazines calls attention to the enormous development of the trade in spurious antique furniture which has marked the last few years. Americans, and, especially, American ladies, have a good deal of the passion for articles possessing some sort of historical association which is natural to people of cultivated minds and lively imagination, who see in their own homes very few objects endowed with such interest, and this sentiment, joined with their wealth, not to say their extravagance, and their inability to judge from experience of the truth of the stories told them, makes them easy victims. It is said that the factories of Rouen alone turn out more than a hundred specimens a day of "antique family clocks"; and the manufacture of old furniture is carried on in nearly every city in Europe. The clumsy old tricks, such as that of firing small shot at a chair or table, to give an imitation of worm-holes, have been superseded by more ingenious ones, and only an expert can detect imposition in such matters. In fact, a large business is now done in furniture actually made of old fragments, originally quite unrelated, but put together in such a way as to make a tolerably consistent whole. Even the ancient fabrics, such as brocades and laces, are now reproduced by thousands of yards, and sold in fragments to unsuspecting tourists, at an enormous price. These objects are sold, in many cases, by agents, who call upon the tourist at his hotel, and pretend to be old family servants, or impoverished heirs, who have come into possession of authentic relics of immense value, which they are willing to sacrifice for ready money; while, in the case of furniture, a great deal of use is made, everywhere in Europe, of cottagers, or inhabitants of dilapidated town houses. These persons are furnished with specimens of fictitious antiquity, which they arrange in such a way as to catch the eye of a person passing. Before long, some credulous tourist is tolerably sure to happen by, and to make the fortunate discovery of this ancient heirloom "in the last place where anybody would have thought of looking for it." After an animated dialogue in broken German or French or Italian, the object changes owners, and is carried away by the triumphant victim, to be immediately replaced by another from the same manufactory. Even with antiquities of a more ambitious class, imposition is the rule. At least two establishments exist, or did exist, not long ago, in Switzerland, which carried on a flourishing business in the manufacture of "relics of the lake-dwellers," consisting of stone spear-heads, and other objects, of course imitated from those in the museums. In the same way, Greece, Italy and Egypt are flooded with spurious "antiques," many of which are made with such skill as to deceive even experts. The fact that the Boston Museum of Fine-Arts has recently removed from its shelves, as spurious, a considerable number of Greek terra-cottas, which had been exhibited as genuine for many years, shows that, where the most eminent judges are occasionally deceived, the amateur collector is practically defenceless.

WE have already mentioned the fact that the highest waterfall in the world was to be utilized in driving turbine wheels. The installation is now complete, and *Le Génie Civil* gives an interesting description of it. The water is derived from a little lake, the Lac de Tanay, situated on the side of a mountain at the upper end of the Lake of Geneva, about three miles from Bouveret. The mountains in this part of the world are steep, and the Lake, or, rather, pond, of Tanay, although so near the Lake of Geneva, is nearly four thousand feet above it. The Lake of Tanay covers something more than one hundred acres, and, by building a dam, can be increased in extent to nearly two thousand acres. A brook runs out of it, with an average flow of about eighty gallons per second; and, with such reservoir capacity for maintaining an even flow, it is not surprising that the idea of utilizing the brook should have attracted the attention of engineers. The first step was to build a power-house at Vouvry, a little station on the Bouveret-St. Maurice Railway, near the foot of the mountain, the upper valleys of which contain the lake. The difference in level between the lake and the power-house is about thirty-one hundred feet, and it was calculated that, with this head, one quart of water per second would give nine and one-half horse-power at the turbines, with all necessary allowance for friction and leakage. At this rate, the little brook would give a constant force of more than three thousand horse-power, but, by increasing the storage, by means of a dam, this could be greatly increased, and the pipes and valves, as well as the plans of the power-station, were arranged for a constant output of ten thousand horse-power. For the present, however, only four machines, of five hundred horse-power each, have been installed. The water is taken from the lake by a tunnel, a thousand feet long, with a slight inclination, and a branch from this tunnel serves as an overflow. From the tunnel the water is carried partly through other tunnels, and partly through pipes, to the power-house. The pipes are of Siemens-Martin steel, welded by hand, the joints being held together with rings and bolts, and kept tight by washers of copper. For the present, it is intended to use the power for the production of electric light, but it can easily be utilized for other purposes, if necessary.

THE *Builder* gives, in a letter from a correspondent, a very easy and useful method of laying-out an elliptical arch. The width and height of the proposed arch being given, a rod is cut, equal in length to the sum of the rise of the arch and one-half the span; and a notch is cut on the rod, at a distance from one end equal to the rise of the arch. A line is then to be drawn vertically through the middle of the proposed arch, and another horizontally across it at the springing line; or a strip of wood may be secured in each of these positions, so that the ends of the notched rod may rest against the strips, and move upon them, Placing the notched rod upright, in contact with the vertical strip, and holding a pencil in the notch, the rod, keeping the pencil in place, is to be moved along the sticks, so that one end is constantly in contact with the vertical stick, while the other is constantly in contact with the horizontal stick. The pencil will then describe one-fourth of a true ellipse, or one-half of a truly elliptical arch of the height and width desired; and, by shifting the rod, the other side of the arch may be drawn in the same way. For the use of plasterers, carpenters and decorators, who often have occasion to lay out elliptical arches of a given height and span, and who can always find three sticks and a pencil, this method is the readiest and simplest that we have ever seen described, and our readers will do well to keep it in mind.

LABOR-ISSUES IN THE BUILDING-TRADES.[1]

THE practical student of labor-issues, no matter in what field he may investigate, is confronted with an almost universal condition — namely, a failure upon the part of the employer to act in the matter of labor as he does in all of the other relations connected with his business. He takes into account the factors of location, of transportation, of climate, of supplies, of cost of material of every name and nature that affect the business in which he is engaged; he assures himself that the parties he purposes dealing with are responsible, he fortifies himself by contracts of agreements so that on these points he may be reasonably assured that he can carry out the contracts he enters into, but he omits to protect himself in the most vulnerable part; like Achilles, he is practically out of danger, save at one point; unlike Achilles, however, the vulnerable part is not remote and insignificant, but in the most conspicuous position and one most open to danger. In spite of all the lessons which the experience of the last fifty years in this country, and a much longer period in the older countries, has offered, employers, as a rule, still go into the market and contract to "do and perform," without reckoning with labor.

The result from this blind policy, or lack of policy, is hardly different from what might fairly be expected: the wide-open gates invite invasion, the unprotected conditions suggests methods of attack, and a strong advance is made by those who see their opportunity and take it.

It is perfectly safe to say that the movement in the social and business world during the last hundred years, which has become known, somewhat too comprehensively perhaps, as "the labor movement," has not concerned, and does not concern, itself with the interest of employers, but is almost wholly addressed to gaining advantages, or supposed advantages, *from* employers and *for* a certain section of those engaged in the world's work, namely, those who work for wages. It may also safely be asserted that a large part of the objectionable features that have resulted from this labor-movement are due to the failure of employers to realize and act upon a common rule of business, namely, that if one does not look out for himself there will be nobody to look out for him. In other words, had employers recognized that labor-issues are as much a part of their concern as of those who are employed by them, and have participated, in legitimate and proper ways, in an effort to systematize and better the conditions under which labor is performed, the dangers which now threaten would have been largely modified, if not wholly avoided. The crux of the whole matter is this: that a field which is indisputably a joint possession has been cultivated exclusively by one party to the equation, with the inevitable result that the crop grown in that field is unsuited to the joint uses of the two parties; and as they *must* live upon the product of the field, and must live *together*, the unsuitable crop distresses and weakens each instead of giving life and strength to both.

What has happened is simple enough in its operation, but terribly complex in its results, and the whole world, awakened at last to the situation, exclaims with one voice that the labor-problem has become the most important and the most difficult of all problems.

These general statements apply to all lines of work, at all events to those lines where any considerable number of individuals are concerned, and, with the increased and increasing facility of communication and of bringing widely separated *small* groups into federated relations, thus making a most considerable interest, there are few lines of work which, at the present time, are outside this general condition of associated action.

The difficulties and dangers inherent in all associated effort are greatly increased by federation, centralization and concentration. Principles which in themselves are, perhaps, simple and admirable become difficult of manipulation and dangerous in application when many of varying nature are put into a crucible with the purpose of making them mingle into a consistent and workable whole.

The temptation is great to exercise undue power and to *force* by these measures of concentration that which can only *safely* come by growth, and the danger in the process is greatly enhanced by the fact that there are no trained minds available to safely direct and control the varied interests thus brought together.

There is no evidence that any one has yet been developed, and it is hardly conceivable that any one will be developed, capable first of comprehending and then of controlling the infinite complexities which cannot but be present in ever varying character in the aggregations of associated interests represented in the large federated or concentrated bodies. It is beyond all experience in Nature and Life to expect such capacity, and yet that is the condition with which the world is confronted, resulting from effort of a one-sided character, unrestrained and untempered by the application of those balancing forces which alone can create and maintain equilibrium.

The labor-problem comprehends three distinct interests — the interest of workmen, the interest of employers, and the interest of the public. It is usual to affirm that in all movements resulting from the agitation of labor-issues the interest of the workman and the interest of the employer are primary interests, almost paramount, while the interest of the community is collateral; but it is not at all certain that this relative position and definition is correct. The community, as the consumer of all products and the customer for all interests, is beginning to claim that its right cannot be ignored, and may *insist* that it shall be first protected.

The movement of the interests, however, has, up to the present time, been largely in the order in which I have first named them — workmen, employers and public, and the character of these movements stated in the same order are aggressive, defensive and passive.

In the evolution of this social economic problem these movements are, in a sense, but natural — that is, they may be expected to occur as stated; but it does not follow that they may not be otherwise ordered, or that they cannot be replaced or adjusted through a wiser, saner process, in a different order and character, resulting from clearer comprehension of the true relation of these interests to one another.

It is easier to comprehend that the wage-worker was first stirred to activity, for it is he who will receive the most immediate and direct benefit from any improvement in conditions. At first he may have groped rather blindly for the changes which he as blindly hoped for, but the initiatory movement could certainly not have been expected from any other quarter, and the groping and blindness were soon supplanted by positive and clearly conceived action. From groping uncertainty to arrogant aggressiveness the stages have been infinitely varied and divided, and though the results in many of their manifestations have been, and are, familiar as household words to this assemblage, it is essential to the purpose of this paper to describe the principal route which the labor-movement has followed and indicate its growth from feebleness to uncontrolled and, apparently, under the present *régime*, uncontrollable power.

In a general way, the movement may be described as following the same route as natural forces, namely, the line of least resistance; for although there has never been a time when barriers have not been set up against the movement, they have been so superficial in character, so weakly unintelligent, that they have almost contributed to the rapidity, if not the smoothness, of the passage.

This line of least resistance has been the employer.

Although the community has always in the last analysis to foot the bill, the demands of labor have never been made directly on the community, but on that servant of the community, the employer of labor, who acts, in a sense, simply as the community's agent, but in such fashion that he ofttimes is subjected to almost all the difficulties and more than his share of the risk and ultimate loss. I shall hope to show before the conclusion of this paper that the time is fast approaching, if not already come, when a reversal of this process will be established, and the community will make its demands on both workmen and employer in a very direct manner, using its power to compel observance of rational rules of conduct in these labor-issues, which have been so radically ignored in these latter days.

Under present conditions demands are presented to, and attacks are made directly upon, an intermediary, who practically engages to deliver either to some specific member of the community or to the community in a more general way certain values which are the joint product of his labor and the labor of those whom he assembles, controls and directs in the process of production. This intermediary, the employer, is, under our present social status, indispensable. While it is possible that under some social polity which the world has not yet practised, a way may be found to dispense with the employer of labor, a way by which every one may work directly with and for the community, it is unquestionably true that such a socialistic condition has not yet arrived. But it is too plain to escape notice that in all the movements made by labor through its organized forces and under the conditions which I have described as existing, the principal effort, tendency and result is to injure this same indispensable intermediary — the employer. It is of course true that when an injury to either workman or employer occurs in these constantly increasing struggles, the community ultimately bears the burden, although it is often so thoroughly distributed that little notice is taken, but the aim thus far recognizable in the history of labor-movements is to catch the employer on the hip and make him bear, vicariously, the burden; a burden which, in this concentrated application and through his inability to escape or shift it, temporarily if not permanently cripples him. He is in the line of least possible resistance apparently, and, willy-nilly, he must take the consequences — at all events, he has taken the consequences thus far, and it is generally conceded that the employer's lot, under existing conditions, is not a happy one.

What is the character of this force which makes itself felt so widely, and often with such brutal disregard of individual rights, either of fellow-servants of same degree or those other servants whose work is equally indispensable with those who work for wage? Let us try and discover and define!

The study of associated effort is most interesting, and would be more so were it not for many painful stages through which one must pass in experiencing the character of this force, and one cannot study properly a practical, concrete question like this without experiencing its manifold vexations and suffering from its sharp pinches.

A principle in itself may be most admirable, and an individual in making application of that principle may be as admirable as the principle and ennobled in its application, but let a group of people attempt to operate the principle and almost invariably we have an illustration of the old adage, "Too many cooks spoil the broth."

A curious psychological change takes place when the minds, the souls, of men mingle.

[1] An address by William H. Sayward delivered at the Thirteenth Convention of the National Association of Builders, Washington, D. C., October 28, 1902.

Six or sixty men may individually be capable of dealing with their fellow-men on a given principle with practically the same result, but let them unitedly attempt to operate the principle and it is an altogether different matter, and that which should be a healing and helping becomes a wounding and hindering. I do not wish to convey the idea that this is peculiar to those who are connected with labor-issues *per se*, but rather that, whatever the kinds or conditions of men, their associated effort is full of dangerous possibility however clear the principle which actuates them may be.

In the first place I think we may say that the character of this force is selfish. However altruistic may be the purpose — and almost universally the claim is made of an altruistic purpose — the force as applied is eminently selfish. It is primarily an attempt to gain certain advantages, or supposed advantages, for certain chosen ones, without special consideration, or, rather, concern, for those who may be outside the artificially-fixed boundaries of the sect; but beyond this, and by far the most threatening aspect of the movement, is the deliberate intent to deprive those who may be within the charmed circle, or not in sympathy with its doctrines, of those privileges and rights which, until these notions were promulgated, it was supposed all human beings had as a natural inheritance, and which our American code describes as "life, liberty and the pursuit of happiness." This latter-day cult says you may have life, liberty and the pursuit of happiness only if agreeable to us, and provided it does not conflict with views we may hold, even though we do hold them under no authority from the State and exercise them regardless of the will of the community. The cult says, we are a power outside of the power of State or Nation, and may, and will, traverse all regions on a plan of control which the community cannot successfully interfere with through any of the recognized instruments which usually have compelled the observance of law and order and which have usually been sufficient to uphold the principle that the rights of the individual shall not be interfered with by powers outside the laws of the land.

The character of this force is, secondly, covert, disguised, evasive. Its primary operations are in secret, and its designs are hidden.

Thirdly, its effect is destructive rather than constructive, and, fourthly, its result is to keep the whole body-politic in a state of disturbance which makes sane and safe conditions practically impossible.

I believe this to be a reasonable statement of the character of this force which has been manifesting itself with ever-increasing significance for the last fifty years and with astounding power and alarming effect during the last dozen years, particularly in the United States.

Having thus briefly described the route which has been taken by the labor-movement and shown how it has naturally assumed authority and clothed itself with power outside all recognized boundaries, I wish to emphasize that power acquired and exercised under conditions where no balancing influences operate is certain to become despotic, and eventually harmful to those who exercise it, as well as to those against whom it is directed; and that we have no right to expect any other result when such conditions are permitted.

I have thus far treated labor-issues generically, and this method might be continued to the end of the discussion which I wish to give to the question, but we are here as builders, and therefore it will be wise to now address myself to those specific manifestations of labor-issues with which we, as builders, are familiar, and endeavor to show how we may modify our attitude so that more satisfactory conditions may prevail in our special business.

What I have said thus far may be considered as introductory to our special interests, and may serve to show that while we have troubles of our own, they are of the same class and character, arise from the same causes, and operate through the same channels as those in all branches of business where labor-issues are a factor, and I hope my conclusions as to what we may, and, I believe, *must*, do in our special field may seem also feasible in any lines which are subjected to difficulties common with ours.

The business of building in any or all of its branches is peculiarly open to disturbances arising from agitation of labor. This is partly the result of the preponderance of a lower grade of service than in some other lines, for instance, the finer lines of manufacture, which invite a perhaps higher intelligence than the ruder, harder tasks incident for the most part to building-work; but by far the greater influence which makes the building-business more liable than many others to these harassing troubles arises from the many distinct trades involved in the production of a single piece of building-work. The simplest structure, the least important undertaking in the building-line, calls into operation, on the premises, many distinct trades, all of them practically essential, the absence of any one making a gap which cannot be filled by any substitute, while in the more elaborate undertakings so common under the demands of modern business or domestic life, the trades which contribute to complete such buildings sometimes number more than two score. This great diversity, this specialization, which splits up building-work into so many parts, with a distinct employer and a distinct set of workmen for each part, invites disturbance, by the ease with which the whole machinery of operation toward a completed structure may be blocked. A portion of the work which in its relation to the whole may be absurdly insignificant may become the focal point upon which all the rest depends, and a labor hold-up in that trade may, in practical result, operate as effectively upon the whole building as in the relatively larger trades.

The sympathetic movement, of course, becomes peculiarly significant in the building-business, whether it be operated upon a single building, to bring either a general contractor or a sub-contractor to terms, or whether it be applied to a general group in a community, to bring all to terms.

One of the newer and most trying developments in later years is that arising from the conflicting claims of rival Unions in the same trade; with no grievances against the employer by either of the rival bodies, their grievances against one another are made to result in more injury to the employer, an injury which even the most easy and conciliatory of employers can find no escape from.

No doubt, many of the employers present here can furnish a long list of actual occurrences illustrating how the diversity of occupations grouped under the one general head, building-work, produces a danger which perhaps does not exist in such extravagant manifestation in any other calling.

From the character of actual disturbances that are taking place in the building-business under the present *régime*, one can readily understand that the opportunity for disturbance is practically limitless.

It seems to me that what I have said, coupled with what you, as practical men engaged in carrying on the various branches of building-work, know from your individual experience and observation, indicates beyond question that, as the case stands at present, the relations of employer and workmen in the building-trades are far from ideal, indeed they are full of danger as a building-proposition, not to say anything of the unsettling, undermining and, possibly, destroying of inspiration, satisfaction, delight in working out problems of construction or decoration upon which depends the development of power and ability to these ends in both employer and workman.

I would like to discuss somewhat fully this demoralization of purpose in work, which flows very directly from the maladjustment of relations of employer and workman, but it is more purely the business aspect of the question which engages me, and which is enough for the reasonable limit of a single paper. I will simply say in passing, however, that there is much in the attitude of antagonism of these two elements that tends to breed deterioration in quality of work; the workman who is constantly urged through unwise and inflammatory counsels, in his organization or elsewhere, to seek solely what he can get, the *uttermost*, without much consideration as to what he shall give in exchange, gradually loses all other purpose, and, by the inevitable working of the law of cause and effect, the question of quality in what he does drifts, without his deliberate intent, into the background and finally disappears; while the employer, gradually ceasing to expect that which he is forced to believe he cannot get, lapses into the same attitude of get-as-much and give-as-little as possible.

Under such conditions as these, the ability to execute becomes gradually a lost art. This is no fairy tale, as many of you can testify, who already find it difficult to secure skilful hands to manipulate stone and iron and wood and all the materials for building into structures and things of usefulness and beauty.

The business aspect of the situation is most appalling.

I can conceive of no more threatening condition than that which grows more and more impressively evident as ultimately possible with every new phase of the labor-problem now rapidly developing in every direction.

While the disturbances which quickly reach the individual, so that he personally feels their sharp pinch, like the coal strike, for instance, appeal glaringly to the public and result in volumes of wise and unwise discussion, mostly from those who have no practical experience in the fields of work involved, who "never set a squadron in the field nor the division of a battle know" more than a spinster, the disturbances that take place in the building and other trades are none the less destructive, though the public, from the smallest and most insignificant consumer up to the President, be not keenly on the alert and insistent that "something be done" to ameliorate the conditions.

Labor-issues in the building-trades are fully as difficult to meet as those of any business, not excluding the business of mining coal; indeed, I think more so, and, as respects the extent or volume involved, either in money values or number of workmen affected, there is but little question that it — the difficulty — is equalled in few callings. I have previously indicated how the problem with us is complicated by the number of trades that are inextricably interwoven — the *completion* of a building being as dependent upon one as another — and I wish to emphasize the point now, as the action which I shall immediately recommend is made more imperative by the complexity referred to. The building-business is not, like mining or manufacturing, concerned principally with one general movement and one product, but is made up of many independent parts, independently conducted.

The independently conducted parts of a whole movement, as in the building-business, make possible a pressure upon the whole through some comparatively insignificant part. This interdependence is suggestive. It suggests weakness, and strangely enough, it suggests strength — and most of all, it suggests obligation. It suggests weakness because insufficiency in any one part blocks the wheels of all parts; and it suggests strength because under intelligent direction, based upon a proper principle of action, all parts may act together to defend any one or more parts from attacks that may be instituted against them. The suggestion of obligation is the strongest, because each part may not, with a proper sense of its duty to the other parts, pursue a course which may result in injury to all,

and for this reason, in the building-business more than any other, each of the blended trades should, in these labor-issues, feel its obligation to so arrange its affairs that others may not be made to suffer on its account.

Three compelling reasons exist for the adoption of a consistent policy as regards labor-issues in this business which immediately concerns us.

1. *Obligation* of each part to every other part.
2. *Weakness* which prevails most peculiarly in the building-business where there is no common policy.
3. *Strength* which is peculiarly available for the building-business when a common policy is positively adhered to.

Now, what policy *is* possible?

It would be a useless consumption of your time and mine, if this discussion should not bear fruit in the shape at least of a suggestion of possible remedy for what I believe to be a most serious mistake in the attitude of employers generally toward the labor-problem, and especially *our* labor-problem.

I am of the opinion that the attitude of employers generally in all kinds of business where labor is an issue should be radically changed. Instead of holding themselves as they too often do, either indifferent or opposed to organizations of workmen, I feel that they should take the matter up with liveliest interest and determination and insist that workmen in their various trades *shall* be organized; that they, the employers, will have no settled policy with them until they be organized; and organized in such fashion as will produce proper, and therefore safe, bodies to be recognized; that they, the employers, will coöperate with the workmen to this end, and that the organizations thus formed will be treated with in fullest, freest and most open manner, so that agreements shall be made at seasonable times of the year, governing terms and conditions for each coming year, or series of years, these agreements to be made public so that the community may know what the contract is and where to place the blame if contracts are not kept. Such a policy of participation will render it practically impossible for the affairs of labor-organizations to be one-sided or to drift into the hands of unworthy or dangerous men. The one safeguard that workmen's organizations need, to make them wholly valuable, is the coöperation of employers. I will not say they are entirely helpless without this coöperation, but I may say with truth that this coöperation will be their greatest defence against those evils which now most glaringly assail them and so often discredit them in the eyes of the public. At all events, an intelligent recognition by employers of the fact that they are a part of the labor-problem, that no inattention or discrediting on their part can alter the fact, but, on the other hand, that frank and complete co-operation insisted upon as, not only a duty, but a right, will furnish the element so greatly needed to balance a machine which often has seemed ill-adjusted for the work it aims to accomplish.

A policy of this nature, persistently and patiently followed, will put the employer in the same relation to the element of labor that he is to the other elements which, as I pointed out in the beginning of this paper, he feels it imperative should be fixed and stable in order that he may secure in his undertakings.

Now, what are the difficulties?

There are many, but none, I believe, so great that they may not be surmounted.

In the first place we have the difficulty arising from the prejudice which an untenable attitude and unwholesome action on the part of labor-organizations have engendered, and from the fact that in many cases their leaders have been irreconcilables and wholly unworthy of the important offices they have been permitted to fill; but I wish to make my belief entirely clear, that this prejudice will vanish when coöperation modifies the action taken, and puts that power of selection back into the hands of the conservative rank and file which has ofttimes been wrested from them; for be it also clearly understood that when I say that "labor must be reckoned with" I do not mean any and everything which presents itself as labor, or as a representation of labor — it may be a counterfeit presentment — but until employers put themselves in a position where they can participate in the issues, they cannot tell the true from the false and cannot help the true to oust the false. Employers must get near enough to the problem to be able to understand the difficulties which the honest and true men in labor-organizations have to struggle with, and it is only by so doing that they can help the good element to overcome the dangerous and bad. Wherever you find a labor-organization which constantly assumes the attitude and acts upon the assumption that the employer is an enemy to be attacked — alas, this is too often the sentiment which prevails — there you will find an organization which has drifted away from wise counsellors and into the hands of demagogues and dangerous men, and that is the organization which, more than any other, needs the help of the employer to rescue it from the danger into which it has fallen; — for an organization which fosters this sentiment of antagonism widens the breach, increases difficulties and deteriorates character. It needs help. Shall it be denied?

On the other hand, I wish to express with equal emphasis that when you find an organization of employers which goes no deeper into the labor-problem than to resist indiscriminately all measures sought by labor, and fails to address itself to the more significant and promising effort of coöperating with labor in an intelligent way, so that labor may be saved from its self-inflicted errors — and, alas, too many organizations of employers and too many individual employers seem to have no clearer vision of their opportunity and duty than this — there you will have an element which tends to increase rather than diminish the conflict between capital and labor, that conflict which has no sane reason for existence.

Another difficulty to be overcome is that sentiment so often expressed by employers that they will not treat with unions *until* they reform themselves and become proper bodies to deal with. This must be met by showing that the chief hope of reform lies in the introduction of that element which the employer alone can furnish and that to demand that the reform must be effected *before* this element be introduced is of the same nature as the restriction placed by a mother on her child, when she insisted he should not go into the water until he had learned to swim!

Another, and one of the greatest of difficulties in the way of setting up new and more wholesome relations, is the unfortunate attitude which unions have assumed toward non-unionists, and which they seem disinclined in most instances to either abandon or modify.

If we put ourselves in their places, I think we may readily understand how this feeling has become deeply rooted. Human nature is about the same whether it be of one condition of life or another, and we are all liable to become prejudiced against those who persistently oppose us. We must grant that the great bulk of those who are members of trade-unions believe in them thoroughly as their only hope for betterment of conditions, and in this view our intelligence and our fairness compel us to concur, even though we may severally condemn some general principles of action and many specific acts — for it is plain that employers or the public generally would not of their own motion have brought about the changes which the unions have secured — and we must also admit that non-unionists have participated in the general improvement. Is it not easy, therefore, to understand why the union man, as a rule, looks with contempt upon the man who sneers and flouts him, refuses to pay his share of the bill of expense, and yet takes all the gain that others have won?

It is easy of comprehension, I say, this deep-rooted antagonism of the union man against the non-union man, and yet, twist it how we may, there is a still deeper rooted feeling which compels us to say that, however galling it may be for a group of men to see others profiting in an increase of wages or by a reduction of hours secured through their concentrated efforts, *the inherent right of the individual to work or not to work must not be interfered with.* This principle is so based on the very foundation of our faith in independence of action, that independence for which this country stands, that it cannot be successfully assaulted; therefore it is the height of unwisdom for labor-unions to make it an issue. As has recently been well said by a sociological writer, "unions have rights to be as exclusive as they please and are within their rights so long as they control only the labor and movements of their own members, but they pass the limits of right and common justice the moment they use their organizations, either directly or indirectly, to exclude even one human being from the chance to make his own livelihood in his own way." This right to make a livelihood is inalienable in every human being so long as he does it within the law, and any man or any group of men who set themselves up against it injure their own cause by so doing. They injure their own cause also by setting up an argument which, if tenable at all, is equally tenable against themselves, for if the non-union man cannot, without interference, pursue any lawful course under any agreement or condition agreeable to him, then the union man must submit to the same injustice. It is time for unions to drop this most unfruitful endeavor; it is time for them, for their own good, to quit claiming that *they* have the right to work or not to work, and then, by the measures they adopt or support their members in adopting, practically deny that right to others.

It is my thorough conviction that the quickest road out of this folly is to coöperate with unions to help them, among other things, to see that this non-union opposition is wholly untenable; it will then soon cease to be a factor. As the attitude of resistance has created evils and dangers, so will coöperation banish them.

If employers abandon their distrust of unions and enter into friendly business relations with them, unions must abandon their distrust of non-union men and concede the right of their fellow-workmen to join, or refrain from joining, their bodies. If a labor-union is recognized as a fit and proper representative body to act for the class — and it must be fit and proper and representative or it cannot be dealt with — then all is gained which it may properly seek; and, by the abandonment of its attempt to coerce people into joining, it opens the surest road for accession to its ranks of those who may *come* of their own accord, but *won't be driven.* Relieve the unions of unworthy methods (and coöperation by employers will accomplish this more quickly than anything else), and those who now object to joining will be much more ready to do so, and if they still stay outside and no notice be taken of them, it will soon be demonstrated that they are entirely harmless, because they have no effect. When employers and employés take each other mutually into confidence and thoroughly discuss matters of mutual concern, antagonism to labor-unions, to employers of labor and to non-union men will soon disappear; and I further believe, and my belief is based upon actual experience, that if the dropping off of non-union opposition be made a prerequisite of recognition, it will be dropped without hesitation.

Two minor difficulties should be mentioned. One is the trouble connected with joint-committee work, which every employer holds as

a bugbear, and the other the claim that labor-organizations should be incorporated so that they may be held financially responsible for their acts, even as the capital of employers is the basis of their responsibility. As to this last feature, I must confess that I see very little real increase of responsibility, such responsibility as is argued for, financial responsibility, through incorporation, unless the capital of such corporations should be very great (a practical impossibility) and made available only for damages under broken agreements; but I *do* think that employers and workmen alike should seek to give their respective organizations some legal status which should result in making them subject to removal of rights granted under State charters when failing to adhere to agreements, or causing stoppages of work, or creating interference with privileges and rights of others. As to the objection that any form of coöperation entails trouble, I can only reply that this is a most unworthy plea; better any amount of trouble to defend ourselves and the community from the harassment and larger trouble which is inevitably connected with strikes and lock-outs.

In summing up it may be said that in labor-issues, either for the building-trades or other lines of work, these intricate and involved matters will not take care of themselves; they cannot safely be entrusted to *one* of the interested parties alone; *both* parties must have equal concern, must act *jointly*, not only in their own interests, but, in effect, in the interests of the community.

This being done and agreements formally made and legally entered into, if *contracts* are then broken it will be *penalty*, not *arbitration*, and the community will be the chief factor in imposing the penalty.

Now, in conclusion, I wish to point out what seems to me a peculiar advantage for the building-trades in carrying out this policy, showing, as I have previously indicated, the strength given by the very conditions which primarily seem a cause of weakness. It will be remembered that I endeavored to show that the diversity of trades involved in each and every building-operation, each trade standing by itself, with a distinct employer and a distinct set of workmen, gave opportunity for almost limitless interference; in some cases a small and comparatively insignificant trade blocking progress of work as effectually as a larger trade. This may be turned to advantage by so concentrating the action of employers that any strike in any single trade, even on the work of a single employer, shall result in a lock-out of all trades by all employers.

This is coercive action, and it should be the study of employers to avoid it. But it would be legitimate under certain conditions which I will endeavor to indicate, in describing specifically how I think these labor-issues can be most effectively met on the lines of the policy I have been discussing.

I should begin by having those employers in the various building-trades, the best, the most responsible in each branch in every community, united together for the specific purpose of dealing with labor-issues. I should have this central body, acting in the general interest, at a seasonable time in each year, issue a call to all organizations of workmen in these various trades, requesting that they formulate their desires as to wages, hours and general conditions for the coming year, and transmit them to the central employers' organization, this latter organization committing itself to laying the desires of the workmen thus expressed before the employers' organizations in each respective trade, and engaging still further to bring about agreements between the employers and workmen through joint conferences. All conferences to be upon a uniform plan and all agreements to be under the observation of the central body, in order that there may be no conflict in the terms and conditions of the various trades.

These agreements being effected and made public, so that the community may understand exactly what has been done in its interest, the central body will then be in a position to demand and secure observance by both parties of the terms of the agreement.

For instance, should any branch be embarrassed by stoppage of work in apparent violation of the agreement, the central body will immediately take it up and make public investigation and fix the blame and penalty. Should the blame be upon an employers' organization, it would have to withdraw from the position taken, or lose affiliation with, and the support of, all the rest of the central body; a serious matter. Should the blame be upon a workman's organization it would have to withdraw from the position taken, or the central body would at once cause all work to be stopped in all trades; an equally serious matter, and one which would speedily end the recalcitrancy of the guilty organization.

If it be too difficult to get a central body thus effectively organized, the same thing can be accomplished by the most prominent general contractors banding themselves together for the same purpose and with the same policy of action. In some respects this is the more attractive form, inasmuch as it limits those who must be in harmony to a much smaller number. But, in any event, this line of action gets all its strength and value upon setting up preliminary agreements to settle all matters of mutual concern by and through joint committees, these joint committees to formulate working rules under said agreements.

With these agreements existing, it will be hard for either party to evade the penalty which breaking of the contract will bring, hard for the guilty parties to avoid the just condemnation of the public.

But, in my opinion, and this opinion is based upon many years of experience, the discipline spoken of will rarely, if ever, have to be applied, for agreements fairly entered into and made public are seldom violated.

I have one word more and a suggestive one.

I received a letter last week from one of our good builders, a man of large experience and extensive business operations, a letter in reply to an urgent request from me that he be present and discuss this most important topic. He wrote, "I am sorry. I should like to be with you in Washington, but I am too much occupied with actual business to spare the time."

Ah, my friends, until employers realize that the labor-problem is as much "actual business" as any part of that "business" which seemingly demands their whole attention, they will fail to take those steps which the old adage comprehended when it declared that "An ounce of prevention is worth a pound of cure," and they will go on as they have in the past, blunderingly refusing to protect themselves and honest workmen against the dangers that threaten, and permitting bad men and measures to obtain control.

PURIFICATION OF SEWAGE.[1]

HERE is, perhaps, no more difficult problem to be solved than the successful purification of sewage, and certainly nothing has given so much hope of a satisfactory solution of the difficulty as the recent experiments which have been conducted on bacteriological lines. In the past, many methods have been tried with more or less success, but none have been supported by scientific investigation to the extent accorded to this system. Exhaustive experiments have been carried out on bacteriological lines in many towns in England, especially in Exeter, Manchester, Leeds, and, under my own direction, at Leicester. The particulars and results of the Leicester experiments were fully set forth in the report I prepared thereon, and largely embodied also in the evidence I had the honor of giving before Lord Iddesleigh's Royal Commission on Sewage Disposal. The workers in the bacterial purification of sewage have become very numerous, but one may fairly mention broadly such distinguished men as Klein, Houston, Frankland, Roscoe, Woodhead, Parry Laws and Andrews, Dibdin and Thudicum, Clowes, Dupre, Adney, Rideal, Scott-Moncrieff, Waring and Ducat, and the well-known eminent officers of Lord Iddesleigh's Commission.

Much credit is also due to Mr. Cameron, the late City Surveyor of Exeter, for the untiring energy and ability with which he has devoted himself to his now famous idea of adapting to modern bacteriological practice the septic action which has for ages past prevailed in the old and familiar cesspool, but with this difference, that, although some advantage was derived from partial liquefaction of solid matters in those cesspools, they were a source of great danger to health from defective design and construction and from their close proximity to dwellings and sources of drinking-water, and the offensive overflowing liquid therefrom dangerously polluted the neighboring ditches and brooks; while Mr. Cameron's septic tanks, with his excellent automatic appliances, are so designed, arranged and located as to effect a large amount of liquefaction of suspended matters without the drawbacks and dangers peculiar to the old cesspool. The effluent from the septic tanks, which is usually then treated on bacteria-beds on the intermittent-contact system as introduced and developed by Dibdin, is passed through one, two, or three beds successively, according to the strength of the sewage, in order to reach the necessary standard of purity. The continuous process of slow filtration through bacteria-beds is now also much advocated by some; it is really the old system of filtration, but adapted to modern practice. It has not yet, however, made such successful headway as the contact, or intermittent, system.

Broadly speaking, the respective artificial bacterial systems, apart from land treatment, which are now practised may be grouped as follows: —

Ordinary subsidence-tanks of comparatively small capacity, followed either by contact-beds or continuous filtration in beds; open or closed septic tanks, followed by contact-beds or continuous-filtration beds; contact-beds or continuous filtration alone.

In some towns where the trade liquids render the sewage very stubborn to treatment, some preliminary chemical precipitation, in conjunction with subsidence-tanks and contact-beds, or continuous-filtration beds, has been resorted to. These artificial processes are defined and dealt with in detail by the present Royal Commission.

There are several combinations of these systems which cannot be done justice to in the scope of this address; but from my own experiments, extending over a period of thirteen and a half months, treating volumes of 60,000 to 467,000 gallons per day by seventeen different processes, I have been led to certain conclusions, which I will briefly refer to, viz: —

That neither contact-beds nor continuous-filtration beds, without previous treatment of the sewage, will be permanently successful unless the sewage is extremely weak and largely free from matters in suspension.

That open or closed detritus, or subsidence, tanks, with a capacity of about one-sixth of the dry-weather flow per day, in conjunction

[1] Extract from the Presidential Address of Mr. E. George Mawbey at the Annual Congress of the Royal Institute of Public Health.

with first and second and, where necessary, third contact-beds, effect a thoroughly efficient purification, and in these experiments gave, with two contact-beds, an average purification of 83 12 per cent in albuminoid ammonia, and 90.15 per cent in oxygen absorbed, at 80 degrees Fahr., in four hours, the average strength of the crude sewage being 1.2481 grains per gallon of albuminoid ammonia, and 7.5929 grains per gallon of oxygen absorbed. The same process, but with the addition of a third contact-bed, gave an average purification of 86.74 per cent in albuminoid ammonia, and 91.32 per cent in oxygen absorbed, the average strength of the crude sewage being 1.3641 grains per gallon of albuminoid ammonia, and 7.8160 grains per gallon of oxygen absorbed.

The experiments with the use of a closed detritus tank, followed by a closed septic tank, and then double contact beds, gave an average purification of 79.91 per cent in albuminoid ammonia and 89.72 per cent in oxygen absorbed, the average strength of the crude sewage being 1.0094 grains per gallon of albuminoid ammonia and 7.2152 grains per gallon of oxygen absorbed; and this same process, but with the addition of a third contact-bed, gave an average purification of 83.68 per cent in albuminoid ammonia and 89.64 per cent in oxygen absorbed, the average strength of the crude sewage being .8837 grains per gallon of albuminoid ammonia and 7.2019 grains per gallon of oxygen absorbed. In these last two experiments, the volume treated in the septic tank for each twenty-four hours was equal to one and a quarter times its capacity in addition to the detritus tank.

Other important experiments which were carried out throughout the whole thirteen and a half months included the preliminary bacterial treatment of the sewage, with final purification on old pasture-land with a heavy clay subsoil. The most successful of these was an eight months' continuous test of treatment with a closed detritus tank, worked at the rate per day of six and three-quarters times its capacity, then through first-contact bacteria-beds (three fillings a day), with final purification by broad irrigation on the old pasture. An average of numerous analyses gave a purification effected of 86.76 per cent in albuminoid ammonia and 91.08 per cent in oxygen absorbed, the average strength of the crude sewage being 1.1823 grains per gallon of albuminoid ammonia and 7.4419 grains per gallon of oxygen absorbed. It will be seen that this process of detritus tank, first contact-beds, and broad irrigation effects a purification quite equal to closed detritus tanks with triple treatment in contact-beds.

For the last eleven years, the bulk of the sewage at Leicester has been efficiently purified by broad irrigation on a farm with a heavy clay subsoil; 1,350 acres have been specially laid out on a newly devised method, so that the effluent from the drains as well as from the surface can be intercepted and treated over and over again until a high standard is reached, and upon this work we expended about £60,000. Owing, however, to the great increase of the population, and the abolition of a subsidiary sewage-farm, it was found necessary to enlarge the system of treatment, and these experiments were carried out with the object of deciding (1) whether it would be better to increase the area of land laid out, (2) or adopt a system of preliminary clarification with subsequent final purification on the land without extension, (3) or even to adopt complete bacterial treatment to supersede the land.

The results of these experiments proved that the second-mentioned scheme — viz, bacterial clarification and land — gave an effluent at least equal to the best system of bacterial treatment on artificial lines, and the utilization of the land already laid out gives a greater certainty of permanent success than there has yet been time to establish in connection with complete bacterial treatment.

One very important fact in connection with this system is that the clarified effluent from the detritus tank and first contact-bed does not, when applied to broad irrigation, foul the grass land; in fact, in my opinion, it is an almost ideal process where plenty of land is available. I therefore designed a scheme to deal with our eight million gallons of sewage a day, comprising detritus tanks, with a capacity equal to one-sixth the daily dry-weather flow, 12 acres of first-contact bacteria-beds, the clarified effluent therefrom to be finally purified by broad irrigation, chiefly on old pasture and rye-grass land. This scheme, which included some additional pumping-plant and sewerage, estimated to cost about £170,000, has been adopted by the Corporation, and is now before the Local Government Board. I may add that, so satisfactory has been this combined bacterial and land treatment, the Corporation have, on my recommendation, purchased an additional 1,269 acres of this sewage-farm land which they previously held on a lease expiring in about fifteen years' time. — *The Builder.*

NOTES AND CLIPPINGS

A NEW FIRE-EXTINGUISHER. — George C. Hale, ex-Chief of the Kansas City Fire Department, has invented an automatic chemical fire-extinguisher which appears to work well. The invention is in the nature of an addition to or an improvement upon the regular chemical extinguishers, but, instead of the small tanks carried by firemen, a tank capable of holding 500 to 1,000 gallons is installed in the building to be protected. The tank is connected with an automatic alarm which sets the extinguisher in operation, and at the same time notifies the Fire Department. In a recent test a seven-gallon tank was used. This was set up in one corner of a yard. To the tank was attached a line of 1-inch pipe leading to another part of the yard. At the far end of the pipe a regular sprinkler-head was attached and on the ground immediately beneath it material for a good-sized bonfire was piled up. It is in the attachments inside the tank that the main idea is evolved. In the bottom of the tank was seven gallons of a solution of water and bicarbonate of soda. Near the top of the tank there was suspended an open-mouthed bottle containing sulphuric acid. The mouth of the bottle was covered by a circular cap pressed down by a piston descending from a valvular arrangement by which the tank was closed. This piston was connected with a spring, the action of which was to raise the cap off the bottle. This piston was depressed by air pumped into the lead pipe, and it held the bottle upright. When the fire was started and the heat caused an expansion that opened the distant sprinkler-head, the air was released from the pipe, the piston in the tank shot upward and released the bottle, which tilted over and precipitated the acid it contained into the solution of soda. This created a terrific pressure of carbonic-acid gas, which, with the soda-water, was projected with great force from the sprinkler-head. The fire, which had made considerable headway, was extinguished almost instantly. In a subsequent test the air was allowed to leak from the pipe until the pressure was only three pounds, but that proved sufficient to operate the sprinkler. To meet the contingency of premature action on the part of the extinguisher through a leakage of air, a gauge is attached, and Hale is getting up a device by which the indicator on the gauge, when the air is reduced to a certain number of pounds, will make an electrical contact and sound an alarm. In the same manner the release of the air through the opening of the sprinkler-head in case of fire will turn in a fire-alarm. In a closed room the carbonic-acid gas will extinguish a fire by smothering it, without much damage from water. — *N. Y. Evening Post.*

ELECTRIC-RAILWAY REGULATIONS. — The municipal authorities of Leipsic, Germany, appear to take the position that the grade-crossings of an electric street-railway service, when the cars maintain a speed higher than that which vehicles drawn by horses would ordinarily have, constitute a hazard comparable in a number of ways with the grade-crossings of steam-railway tracks; and in the past the street-railway company maintaining its service there has either had men with flags stationed at crossing roads to give warning of approaching cars, or the conductor on one of these cars, on coming to the crossing of a street, has been obliged to run ahead for the purpose of seeing that no vehicle was crossing, or was likely to cross, which would be in any way endangered by the passing of the electric-car. This system has either militated against the time made in running these cars, or has involved a very large outgo in paying the wages of flagmen. The company has

now introduced a system of light-signals at each crossing. Cars coming in one direction, when within a given number of feet of the street-crossing, cause the signal to glow with a red light, or, if coming in the other direction, the signal shows a green light, and this is said, by means of reflectors, to be effective both during the day and night. They are, doubtless, much more careful of human life in Europe than we are in this country, and yet when it is taken into account that our various suburban electric street-car services are frequently run at a speed equal to that of the ordinary railway-trains, and that the modern long-distance electric-car is a very heavy vehicle, it would seem as though this German method of giving warnings at street-crossings is one which might be wisely investigated by supervising authorities in this country, for the purpose of seeing whether its introduction here would not be both feasible and desirable. — *Boston Herald.*

Charlemagne's Burial-place. — The perennial controversy over the exhumation of Charlemagne has revived of late in Germany. It is one of the most desperate of its class. We are accustomed to read, as a simple matter of fact, that the Emperor Otho III resolved to test the value of tradition which asserted that Charlemagne sat in a chair of state beneath the altar of the Church of the Holy Virgin at Aix la Chapelle. In the year 1000 he carried out his purpose. A manuscript almost contemporary gives an account of the operation in the very words, as it professes, of Count Otho of Lourello, Captain of the Imperial Guard, who was present. They cut through an "alcove" by the altar, and found the great King, exactly as legend described him, upright on his throne, the crown upon his head, and the sceptre in his hand, a gold chain round his neck. A snow-white beard covered his chest, and the nails had grown through his gloves. So well had he been embalmed that only the tip of his nose was decayed, and Otho replaced this with gold, removed the crown, sword, and other valuables, also one of the teeth; draped the figure in white, and rebuilt the alcove. The story could not be more circumstantial, and it is told by an eye-witness, apparently. Further, the crown and sword are preserved to this day at Vienna, and no one has ever questioned their authenticity. There was a "talisman" also, which Otho bestowed upon the city; the city presented it 800 years afterwards to Napoleon, who gave it to the Earl of Holland. His representative restored it to Napoleon III, and it is now at the Louvre. Upon the whole, the evidence seems indisputable. But on the other hand we have the positive statement of Eginhard and Thegan, his friends and Ministers, that Charlemagne was buried on the day he died. They say nothing of embalment. It seems very improbable that the science of those days could have preserved the flesh of a man who died of dropsy; certainly it could not have done the work in a few hours. Had it not been for this picturesque story, no one would have questioned that Eginhard's description refers to a simple burial beneath the pavement of the church. But there is another objection. No "alcove" can be found which shows signs of disturbance, and, though the pavement has been tested again and again, no vault can be discovered. Further, the Chronicle of Cologne reports, under the date 1165, that Frederick Barbarossa "lifted the bones of Charlemagne out of the sarcophagus in which they had lain for 351 years." Apparently they had not heard at Cologne of Otho's remarkable discoveries. A sarcophagus is still shown to visitors, but, to complete the confusion, it is far too small to have held the giant. The crown and sword and the rest have still to be accounted for. But it is recorded that when the Danes were advancing on Aix in 880 the treasures of the church were removed to Stablo. It seems more than likely that any valuables in Charlemagne's grave would be sent away with them. — *London Standard.*

The Balzac Statue. — The statue of Balzac ordered by the Paris Society of Men of Letters will be unveiled in the Avenue de Friedland this month. Never was an attempt to honor the memory of a famous writer attended with more difficulties. The Society gave the commission some years ago to the sculptor De Vasselot, who, for some reason best known to himself, produced a sphinx, which was promptly rejected. Then Rodin undertook the work, and produced a Balzac which was likened by adverse critics to a porpoise in a bath-robe. After the flood of discussion which it aroused had subsided, Rodin sold it to a wealthy Englishman. Next Falguière, the noted sculptor, took the commission, and died, after which Dubois finished the work. Even after the statue was done, there was trouble concerning the site and the pedestal, which required more than a year to settle. — *Exchange.*

Russian Izbas. — A fireproof village is the latest plan to which the Russian administration has resorted in order to prevent conflagrations, which have retarded so much the development of Muscovite country lands. It is known that the "izbas," or huts, of the moujiks are built of wood and roofed with straw, so that a whole village is likely to be destroyed entirely if only one hut catches fire. This was the fate of the prosperous village of Bazina. The inhabitants asked the Government for permission to establish themselves in a neighboring locality. Authorization was granted, but on the condition that houses shall be built in a manner different from the traditional one; that is, they should be constructed of fireproof-material. A subsidy of 100 rubles was granted to each inhabitant, and the municipality furnished iron at cost price. The village was built according to those conditions, but the peasants do not like it; the majority of them regret the old "izbas" where their fathers were born and where there is always a chance of being burned alive. — *N. Y. Tribune.*

Cast of the Colleoni for the Boston Museum of Fine-Arts. — The Museum of Fine-Arts has just received, as a gift from Francis Bartlett, of this city, a full-size cast in plaster of the great equestrian statue of Bartolommeo Colleoni in Venice. Negotiations for the production of this copy have been in progress for a number of years. As the supports of the statue are no longer considered strong enough to warrant the taking of a mould directly from the original, the authorities of the Berlin Museum have generously permitted the reproduction of their cast, which is one of three that were made about fifty years ago, the only full-size copies known to exist at the present time. Unfortunately, the Museum has at present no place in which it can exhibit a work of this size and scale, so the new gift will have to be placed in storage to await the growth and completion of the new Museum Building. — *Boston Transcript.*

Burning of the Château d'Eu, near Rouen. — The virtual destruction on November 11 of the Château d'Eu, the seat of the Duke of Orleans, was caused by a fire in one of the chimneys, and owing to the great height of the building the pressure of water was insufficient to reach the flames. The greatest efforts were made to save the art-treasures in the building, but they were not entirely successful. Many objects of great value were destroyed, including two-thirds of the library of 30,000 volumes. Among the art-works which were rescued was a statue of Psyche, which was presented to the late Duke of Orleans on the occasion of his marriage, in 1837, by the city of Paris. A large bronze statue by Princess Marie of Orleans was also saved. — *Exchange.*

Rumored Aztec Find in Mexico. — A remarkable story of the discovery of hidden Aztec treasures has just been reported to the Government authorities at Tepic by the Rev. Pablo Martino, the parish-priest of Yesca. The priest makes a statement, which is concurred in by several reliable witnesses, that a party of Americans headed by an archæologist who gave the name of Heverick arrived at Yesca several weeks ago and went from that place into the mountains accompanied by three Mexican guides. The archæologist directed his course by means of a chart which he claimed to have copied from an Aztec stone tablet in the National Museum in the City of Mexico. He found a vast cavern in a mountain near Yesca. Immense stone images stood about this chamber and in one end was a handsome altar. In a chamber adjoining this main temple was found a great store of ornaments and utensils belonging to the Aztecs, or some other prehistoric race. Twelve burros were required to transport the articles taken from the cave to San Blas, where they were shipped to San Francisco, accompanied by the Americans. As such articles cannot be removed from Mexico without the consent of the Government, an investigation is in progress. — *N. Y. Evening Post.*

Test of a Twenty-story Stand-pipe. — Severe and successful tests were made by the fire-department of the 6-inch stand-pipe in the "Flat-iron" building, at Broadway and Twenty-third St., recently. Chief Croker declared that it had demonstrated that no matter how high a building might be it could be safely protected from fire if properly equipped with stand-pipes. He added that such a pipe as in the "Flat-iron" building erected by the side of the pier of the East River bridge would have saved that structure. The purpose of the test was to determine if the 6-inch pipe would stand the great pressure of twenty three stories of water and to find out how much force could be given to a stream from the hose attached to the stand-pipe at so great an altitude. In the second trial nine streams were thrown, one from each of the eight floors above the twelfth story and one from the roof. Three 4-inch nozzles were used, and a pressure of 200 pounds was obtained upon each of the nozzles. When the trial was finished Chief Croker said: "In every respect the test has been perfectly satisfactory. The stand-pipe in this building is made of galvanized-iron and stands the great pressure all right. Summarized, we have done here with two engines, I might say with one, what it would have taken a second alarm, or eight engines, to do without the aid of the stand-pipe." — *Boston Herald.*

The Seismograph and Bridge Vibration. — An engineer named Omori has become familiar with the apparatus used in detecting and registering earth-tremors through his service on the Imperial Earthquake Commission of Japan. He was thus led to consider the question of utilizing seismometers for another purpose. Some of the strains to which bridges are subjected, especially the ordinary bending from stationary loads, can be easily computed in advance. But another set, due to moving loads, are not so readily ascertained. These are vibrations, up and down, crosswise or endwise. They have more to do with the security or insecurity of a given structure than the bending strains. Mr. Omori has tried his seismometers on bridges long enough to prove that they are so delicate that they will afford valuable information. He advises making tests at regular intervals, as in this manner warning would be given when a bridge was weakening through age. — *N. Y. Tribune.*

Luini's Portraits of the Sforzas. — The municipal museum of Milan has acquired from Count di Cigada fourteen fresco portraits which Bernardino Luini painted on the walls of a house originally belonging to Leonardo da Vinci, but which passed into the possession of a favorite of Duke Ludovico Moro. In order to testify his gratitude this person employed Luini to paint portraits for fourteen members of the Sforza family. For a long time these pictures were attributed to Leonardo, until chronological comparisons proved the impossibility of this theory, and experts decided that they were by Luini, the pupil of Leonardi, whose frescos at Lugano and Milan are among the finest specimens of this art. The portraits mentioned have been carefully detached and cleaned. Particularly impressive is that of Maria Sforza, the defender of national independence, under whose rule art attained its golden age in Lombardy. — *Exchange.*

NOTES AND CLIPPINGS. 72

TRADES-UNION matters are exciting, just now, a public attention which promises well for the future. In this country, publicity is the great purifier of politics, business and social relations generally, and the more frankly and thoroughly the interests of capital and labor are discussed, the sooner a healthy and intelligent public sentiment in regard to them will take the place of the atmosphere of lying, bullying and hypocrisy by which they have been so long obscured. The relations of the coal operators and their men, which are now under searching investigation, afford a lesson of which the public has begun to understand the importance, and it must be confessed that, so far, the operators have not gained much sympathy, and, for them, the loss of the credit which the public was once ready to concede to them is a misfortune, from the effects of which they will not soon recover. Their claim, that thousands of men were ready and anxious to work in the mines during the strike, but were prevented by fear of violence, does not seem to be substantiated. Undoubtedly, the disgraceful Pennsylvania statute, requiring miners to be licensed, kept away a great many men who would have been glad of the work; but the fact appears to be that, notwithstanding the assertions of the operators, a general feeling of dissatisfaction on the part of the miners with their wages, their treatment, and the conditions of their labor, had a great deal more to do with the strike than the operators would have us believe; and that Mr. Mitchell, instead of coercing, by his eloquence and intrigues, a hundred and forty-eight thousand prosperous and happy people into abandoning their work, did little more than put himself at the head of a movement which could not, in any case, have been long delayed.

THE singular unreasonableness of the operators in regard to the mere technicality of recognizing the Mine-Workers' Union does not add to the dignity of their position. That the Mine-Workers' Union exists is a fact beyond dispute, and to refuse to recognize facts is one of the surest indications of incapacity on the part of a business man. The operators say, we are told, that they cannot endure that men brought up in bituminous coal mines should claim to speak for anthracite workers; but if the anthracite workers choose bituminous miners to speak for them, it seems to the public not only tyrannical, but foolish, to refuse to listen to their chosen representatives. The operators say that a bituminous miner cannot possibly understand the conditions of the business of anthracite mining; but the anthracite miners would naturally instruct their representative in matters where such instruction was necessary, and the public cannot avoid the reflection that it has, for many years, been obliged to accept, as representatives of the anthracite operators, railroad presidents, who, to say the least, are not likely to know much more of anthracite mining than the bituminous workers. No one can deny that there is now, in this country, a strong tendency to consolidation, not merely of similar interests, but of those only indirectly allied. The anthracite mines are themselves mostly in the hands of railways; the great Steel Corporation makes rails, builds bridges and other structures, navigates ships, works mines, and carries on many other kinds of business; the Western packing-houses kill hogs and cattle, sell fresh beef, salt pork, sausages and beef extract, and make fancy soap, without public condemnation; yet these various industries are much more diverse than those of digging out anthracite and bituminous coal. That it may be inconvenient at times for the anthracite miners to depend, in conferences with their employers, upon men trained in another business, is quite probable, but that is a matter which, among reasonable men, would soon correct itself; and the operators, by struggling over a question purely nominal, not only discredit their intelligence as business men, to say nothing of their good faith in accepting the intervention of the President's Commission, but expose the public to great danger of the reopening of the conflict through what the miners would have reason to consider a violation of a solemn pledge.

AS usually happens, while the anthracite operators, as employers, are not exhibiting themselves to the public in a favorable light, the employed, in various parts of the country, also show signs of a disposition not yet quite regenerate. Fortunately, the antics of enthusiastic workingmen are much less to be feared than the obstinacy, unreasonableness, or cruelty of those who control great enterprises, or great masses of capital, and it is to be hoped that the display which has of late been made of the astounding tyranny and folly of certain unions may influence public opinion in such a way as to assist the respectable workingmen in taking the control of their affairs out of the hands of the reckless or corrupt schemers who now, in so many cases, manage the unions. It is quite as easy to teach workingmen as railroad presidents that all persons who use the power of combination to prevent other people from getting employment, or from procuring materials for their business, or to injure them in any way, are enemies of the community, and must be dealt with in the way that communities deal with their enemies.

IT is quite time that the reputable unions of mechanics engaged in the building trades should express themselves clearly and emphatically in regard to the blackmailing which is practised upon architects in their name. For several years men, sometimes in pairs and sometimes singly, have made the rounds of the architects' offices, at least in Boston, inviting subscriptions to what purports to be a book of some sort, to be issued under the auspices of a certain labor organization. Nearly all architects have a very friendly feeling for the skilled mechanics who help to transmute their designs into enduring materials, and, when the trick was first practised, many paid the two dollars asked for, or even more, supposing that they were contributing to the benevolent fund of a recognized union. A few weeks later, however, a second deputation presented itself, often in a condition suggesting alcoholic tonics, with another subscription-book. Those charitable architects who had already contributed to the first one were sternly told that this was a totally different affair, conducted by an organization which had nothing to do with the other, but which had it in its power to make a great deal of trouble for architects. Apparently, some of the younger members of the profession were frightened by these threats, for they have been made more openly year by year, until the blackmailers do not hesitate to tell architects who refuse to open their pocket-books that they are liable to have strikes declared against their buildings.

CONSIDERING the narrow income of most architects, and the friendly services which they are always willing to render, and do render, in multitudes of instances, to individual workmen with whom they are brought in contact, this system of compelling contributions by threats in the name of labor organizations is a pure and simple outrage. It is not likely that the working members of the unions know anything about the actions for which they are put forward as responsible; and it is not impossible that the collectors of contributions may be, at least in some cases, mere swindlers, masquerading under the guise of emissaries of labor associations; but it is significant that a motion made at a meeting of the Central Labor Union, in Boston, to investigate and suppress all attempts to collect money from architects by threats in its name, was quietly smothered, and there is reason to believe that some of the officials of the various unions and federations know more about

Entered at the Post-Office at Boston as second-class matter

the matter than they would be willing to acknowledge. However this may be, there is no doubt that the practice is one which every right-minded workingman would repudiate at once, and those who carry it on are bringing the organizations which they profess to represent into contempt among the people who have more influence than any others in the community in securing for workingmen, or, at least, for those workingmen employed in the building trades, the consideration and respect which they themselves feel for men who practise faithfully and skilfully the various arts whose difficulties they are trained to appreciate. It will be a sad day for the building trades when architects and workmen come to regard each other with suspicion and distrust; and the sooner the Federations of Labor, the Knights of Labor, the Central Labor Unions and the other influential and respected organizations of building workmen publicly denounce and repudiate those who use their names for extorting money from architects, the better it will be for the continuance of the relations between those who design and those who execute which have been for so many years pleasant and profitable to both.

THE death of Professor Ogden N. Rood, of Columbia College, has called forth some interesting expressions of gratitude from artists. Professor Rood, as every one knows, while very eminent in all departments of physical science, devoted himself at one period, with conspicuous success, to the theory of color, and published a work on the subject which has long been an authority among scientific men. It is, however, remarkable that artists, who, as a rule, consider "an eye for color" to be a heaven-sent gift, and despise scientific discussion, should have found in Professor Rood's work suggestions which they were not only willing to use, but to be grateful for. Mr. Ruskin, as will be remembered, summed up the duty of students in such matters by saying to his pupils, "Whenever any scientific man tells you that any colors are inharmonious, make a note of those colors, and put them together whenever you possibly can"; and this attitude suits many artists, and many more amateurs; but so accomplished a master of color as Mr. John La Farge is not ashamed to say that Professor Rood's writings were "a consolation to me long ago, in my attempts at disentangling what was right in my instinctive apparitions"; and other painters, little less distinguished as colorists, speak in similar terms.

MR. JULIUS F. MUNCKWITZ, for many years Supervising Architect of the Central Park, in New York, died at his home in that city a few days ago. Mr. Munckwitz was born in Leipsic, seventy-three years ago, but had spent nearly all his life in New York. From the time of the first laying-out of the Central Park he interested himself in its development, and was employed, almost from the first, in various ways in connection with this and other parks, becoming Supervising Architect and Superintendent of Parks in 1871. In that capacity he designed many of the buildings erected in the Central Park. His son, who bears the same name, some years ago succeeded him as Architect of the Park Department.

SOME student of chemistry might do worse than to undertake, perhaps as thesis work, the study of the alloys of aluminium and magnesium. All these alloys are easily made; most of them are less susceptible than pure aluminium to the action of alkaline reagents, and they are lighter than pure aluminium; while some of them have been recently reported to have shown a tensile strength greater than that of steel. If this report should be confirmed, and a compound metal could really be obtained, stronger than steel, and weighing less than one-third as much, at a cost comparable with that of pure aluminium, many industries would be revolutionized, and, above all, the art of navigating the air would receive a development such as nothing else could give it. Until now, although aluminium is a cheap and familiar material, it has not been found practicable to use it in balloons, for the reason that a greater weight of it is required, for a given strength, than of steel. M. Santos-Dumont, who has distinguished himself by his minute study of every detail of aëronautics, employs steel piano wire to suspend the cars of his balloons from the inflated portion, and steel is used in other places where tensile strength is required, while the engines and motors, which form a very large part of the load to be lifted into the air, are also of iron and brass, or copper. If an equal bulk of a metal weighing one-third as much could be substituted for these, an immense increase in power could be obtained, and it is hardly too much to say that the future of the navigation of the air depends upon the discovery of such a metal. According to the chemists, an alloy of equal parts of aluminium and magnesium is extremely brittle, but compounds containing not more than fifteen per cent of either metal are malleable.

THE recent accidents in Paris have greatly diminished the confidence and interest with which the public had begun to regard the modern advance in the art of navigating the air. According to Colonel Espitallier, however, who writes in *Le Génie Civil* as an expert familiar with the circumstances of both cases, each of the accidents was due to neglect of simple and obvious precautions. In the first case, M. Severo d'Albuquerque, a Brazilian, like M. Santos-Dumont, but, apparently, less methodical and cautious, had constructed a balloon of a somewhat novel type, propelled by means of two gas-engines. The car was suspended close under the balloon, and the two gas motors were, in consequence, brought dangerously near the atmosphere of mixed hydrogen and air which always clings to the surface of a balloon. Five years ago, a balloon in Germany, similarly constructed, took fire and exploded in the air; and Colonel Espitallier says that M. Severo should have taken warning from its example; but, instead of this, he even removed the wire-gauze casings with which the maker of the gas-engines had been prudent enough to surround their torches, and, at the same time, fastened up one of the safety-valves of the balloon. The remaining safety-valve was at the rear of the balloon, near the propeller, and almost directly above the rear gas-engine. The hydrogen which would inevitably escape from the safety-valve as soon as the balloon was exposed to the rays of the sun, or rose far enough into the air to feel the diminution of atmospheric pressure, was, therefore, likely to be churned up by the rear propeller, surrounding the end of the balloon with a large volume of an explosive mixture, close to the torch of the gas-engine. At its first trial-flight, with its owner on board, the machine behaved as, perhaps, it might have been expected to do. While it was high in air, a flash was observed at the place of the rear gas motor, followed by a second, and brighter one, as the whole mass of hydrogen in the balloon blazed up, letting the car and its occupant fall to the ground.

THE second accident, which occurred in the middle of October last, was not due to such rash neglect of ordinary precautions, but might, according to Colonel Espitallier, have been avoided by greater care and experience. A German Baron, named Bradsky, had been for two years in Paris, engaged in the construction of a navigable balloon, of a new and meritorious type. Being long and narrow, the balloon was exposed to the pitching due to the movement in it of waves of gas; and, to prevent these, it was divided into sections by silk partitions. Baron Bradsky had arranged for a trial of his invention on the morning of October 13, on the plain of Issy, which would give space for its manœuvres. Unfortunately, his confidence in the balloon was so great that he resolved to sail out to Issy from Paris in it, accompanied by M. Morin, an engineer, and an experienced aëronaut. From the very first, the balloon steered badly, and the wind, which was tolerably fresh, drove it toward the hill of Montmartre. In order to clear the lofty buildings on the hill, the aëronauts threw out so much ballast that the balloon rose high into the air. This caused the gas to expand, and a considerable quantity escaped through the safety-valve. The aëronauts then allowed more gas to escape, in order to descend again, leaving the balloon, when they had approached the surface, only partly filled. When they were within some three hundred feet of the ground, M. Morin spoke to a bystander, M. Aubert, asking him if there was an open space near, where the balloon could be brought safely to the ground. M. Aubert pointed to the village of Gonesse. The wind would not carry them in this direction, and the two aëronauts turned the rudder sharply, and quickened the speed of the screw. The sharp twist given to the balloon by this manœuvre seems to have caused a wave in the half-empty balloon, which caused the gas to accumulate at the rear end, lifting it much higher than the front. The bands and wires connecting the car with the balloon were not properly designed to resist a strain of this sort, and the front wires, on which nearly all the weight was thrown, gave way. As the car dropped, through the parting of these wires, the shock broke the next wires, and so on until the car broke entirely away from the balloon, and fell, killing both its occupants, while the main body of the balloon rose into the air, and was blown far out into the country.

THE HENNEBIQUE SYSTEM OF ARMORED-CONCRETE CONSTRUCTION.[1] — I.

IRON and steel have been used in the construction of railroads, steamships, bridges, office-buildings of stupendous heights, factories, exhibition-palaces, markets, theatres, apartment-houses, grain-elevators, water-towers, stand-pipes, smoke-stacks, and water-mains of hundreds of miles in length. Even churches have been built entirely of iron. It is due to the triumph of iron and steel engineering in the latter half of the past century that our profession is recognized to-day as one of the most honored of human vocations.

I ask, is steel really the most suitable material for all these purposes? Is the engineer (who is defined as a person employing the resources of nature with the least amount of human labor to the benefit of mankind) right in using steel only as the skeleton of his constructions? The universal reign of steel is irrevocably past, and we are returning with rapid strides to the old, time-honored masonry construction.

Not to brick or stone work, but to an artificial stone, *i. e.*, concrete, strengthened by steel. This composite material is variously called concrete-steel, ferro-concrete, or armored concrete. Concrete itself is not a new building material. Vitruvius Pollio, the famous writer on architecture and engineering, who lived in the beginning of our era, describes it as one of the most valuable building-materials,

Fig. 3.

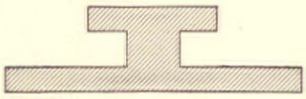

Fig. 4.

and as one which, centuries before his time, had been used for foundations, for walls and in all structures where great strength was required. The great dome of the Pantheon, in Rome, 142 feet in diameter, was built entirely of concrete, and it stands to-day, having braved the destructive influences of nature for nearly two thousand years. In the House of the Vestals, an upper floor of 20 feet span was a simple slab of concrete 14 inches thick. Even in Mexico there are buildings, the remains of an unknown civilization, which have concrete foundations, and in the Italian colonies of Magna Græcia, there is evidence that the ancient Greeks knew what concrete was and how to apply it. The walls of Reading Abbey, in England, were apparently faced with square blocks of stone on both sides, and the core and backing were made of concrete, with the result that, although the stone appears to have perished, the concrete, which was intended to play a secondary part, still remains.

At Badajos, in Spain, the walls of the castle and fortifications still show the marks of the boards used for the moulds. In all parts of the world there is evidence that concrete, as a building-material, was well known and largely used many hundred years since, long before the general introduction of steel and other artificial substances, now recognized as legitimate materials of construction. As Portland-cement was unknown eighty years ago, all the concretes named had lime for their cementitious constituent; but the excellent quality of the lime, and the apparent care and knowledge applied in the selection of the component parts, resulted in the construction of buildings superior in strength and durability to any of modern erection, sky-scrapers not excepted.

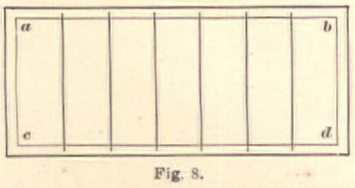

Fig. 8.

The use of concrete alone, however, is confined to that limited number of cases where economy in time and labor does not enter into consideration. This is because concrete has a comparatively high compressive strength, but a very low tenacity, thus forming, like cast-iron, a very uneconomical material of construction. To illustrate this point further, let us consider a concrete beam, *A B* (Fig. 1), of rectangular section, supported at the ends and loaded. The beam will deflect, the upper fibres will be in compression, the lower fibres in tension. The greatest stresses occur in the extreme fibres at top and bottom and are of the same magnitude. The nearer we come to the centre of the beam, called the neutral axis, the less will be the stresses. Their distribution in any section of the beam is graphically represented by the diagram *a a′ n b b′*. The greater the load the greater will be the extreme fibre stresses, and, in increasing the load, we reach a point where the ultimate tensile strength is reached and the beam fails. It fails because the lower part of it, which is in tension, is destroyed, while the upper part is strained to only from one-tenth to one-twentieth of its ultimate strength, concrete having a tenacity of about 200 to 250 pounds per square inch and a compressive strength of 2,000 to 3,000 pounds per square inch after two months, which might increase to 5,000 pounds after two years. This unfortunate property of concrete can easily be remedied by embedding steel rods where tensile stresses might occur. This expedient, however, is not new. Monier, a Frenchman, as early as 1876, took out his first patent on concrete-steel construction, and thousands of water-tanks, sewers and water-mains were built of concrete armored with wire nets, and a new field and new possibilities were opened, which will soon revolutionize our building-practice.

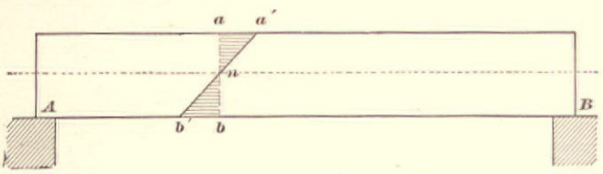

Fig. 1.

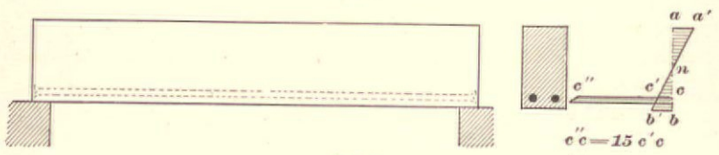

Fig. 2.

All rational combinations of concrete and steel are based on the following facts: —

First. — The coefficients of expansion of concrete and of steel are practically equal, as many scientists of Europe and America have demonstrated.

Second. — A perfect bond exists between concrete and steel. Their adherence has been determined by different authorities, and found to be 570 to 650 pounds per square inch.[2]

Third. — The concrete fully protects the iron against corrosion.[3] We know, besides, that iron nails were preserved by the mortar of Roman walls for 2,000 years, and in view of this fact can we doubt the preservative efficiency of our first-class Portland-cements?

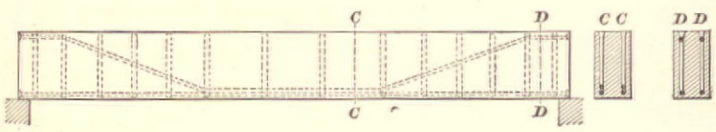

Fig. 5.

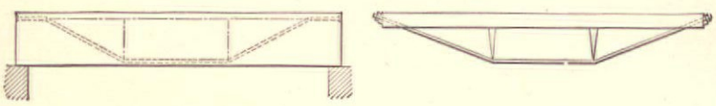

Fig. 6.

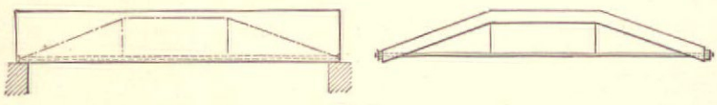

Fig. 7.

Fourth. — The ratio of the moduli of elasticity of concrete and steel is as 1 : 15. In other words, if two fibres of concrete and of steel, respectively, of the same length, be subjected to equal elongations, their stresses will be in the ratio of 1 : 15.

Let us now revert to our concrete beam, embed steel rods in the lower part and apply our loads. The beam will again deflect, the upper fibres will be in compression and the lower fibres in

[1] A paper by Mr. Leopold Mensch, C. E., read at a meeting of the Civil Engineers' Club of Cleveland, and printed in the *Journal* of the Association of Engineering Societies.

[2] It may be interesting to know what the length of an iron rod, embedded in concrete, must be in order that it may fail by tension before rupturing the bond. If we assume the ultimate tensile strength of iron to be 57,000 pounds per square inch, we have the force required for breaking the rod bodily $= 57{,}000 \frac{\pi d^2}{4}$; for breaking the bond the force required $= l\, d\, \pi \times 570$; $l\, d\, \pi$ being $=$ area of surface in contact. Equating these two expressions, we get, as minimum length, $l = 25\, d$. Thus, if a bar of round iron has a length of more than twenty-five times its diameter, it will break before it can separate from the concrete.

[3] An experience of 2,500 years has proved that concrete is absolutely indestructible, that it resists the disintegrating effects of air, moisture, water and steam, even of sea-water and of sulphuric and chlorine gases; and that, if the metal embedded in concrete were not thus protected by the latter, concrete-steel structures would be impracticable. Happily, however, wherever such work has been taken up after years of exposure, the steel has been found free from any trace of oxidation. To remove any possible doubt, Mr. Hennebique resolved to urge upon the city authorities of Grenoble, France, an official investigation into the preservation of steel in concrete. In that city a water-main, constructed on the Monier system, of 12 inches internal diameter and 1⅜ inches thickness, laid in 1886, had borne, for fifteen years, a head of 75 feet of water. The sections of the pipe were 6 feet 3 inches long, and the iron skeleton was formed by thirty longitudinal rods, ¼ inch in diameter, one interior spiral of 5-32-inch wire and one exterior spiral of ¼-inch wire.

On February 2, 1901, 16 feet of this conduit were taken up. The tubes were found in a perfect state of preservation; the steel did not show the slightest trace of oxidation; the adhesion of the steel to the concrete, despite the slight thickness of the pipes, was such that it could be separated only by heavy blows from a sledge-hammer.

tension; but the diagram of stresses, which in Figure 1 was represented by $a\,a'\,n\,b\,b'$, is now distorted by the new stresses which are produced in the steel rods, forming the diagram $a\,a'\,n\,b\,b'\,c'\,c''$ (Fig. 2). We have learned that a perfect bond exists between the steel and concrete, therefore it is evident that the extension of each steel fibre is the same as that of the adjacent concrete fibre. But, by the fact stated above, this involves stresses in the steel fibres fifteen times as great as in the adjacent concrete fibres, since these are necessarily at the same distance from the neutral axis. This has the same effect on the moment-of-resistance of the beam as if we had added to the lower part of the section an area of concrete having fifteen times the area of cross-section of the steel rods (Fig. 3). This will at once be recognized as the section which, in rational design, is given to cast-iron girders; but the great difference is that, in our case, we get a very considerable increase in strength of section with only a very small increase in weight. The more steel we embed, the less will be the tensile stresses in the concrete itself and the greater will be the part of the tensile stresses taken by the steel. In fact, in all rational designs the resistance of the concrete to tension is entirely disregarded.

Fig. 9.

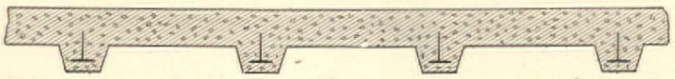

Fig. 10.

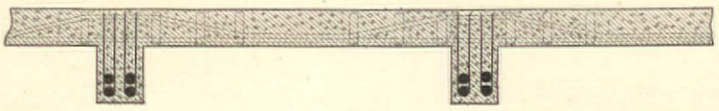

Fig. 11.

But we have to guard against an excess of steel. If the ideal T-section becomes excessively wide at the base, the relatively small compression-flange, formed by the concrete, has to take too large a compressive stress, and might fail by crushing. We thus see that, in a given section, there can be but one proper proportion of steel to concrete. In building-practice there are many cases where the depth of the beam is limited, and where a very high capacity is required. In such cases we can further strengthen the beam by embedding steel rods in the upper part of the section, as well as in the lower part. This gives an ideal T-section, as shown in Figure 4. It is clear that we require a less area of steel in the upper than in the lower part, and we must maintain the proper ratio between the moments-of-resistance of the top and bottom flanges. Otherwise waste of material or failure of the beam will follow.

As in any steel and wooden beam, we have also to take care of the shearing stresses. The first engineer who grasped the importance of this consideration in connection with the strength of concrete beams was M. François Hennebique, and his scientific designs have made him the most successful concrete-steel builder in Europe.

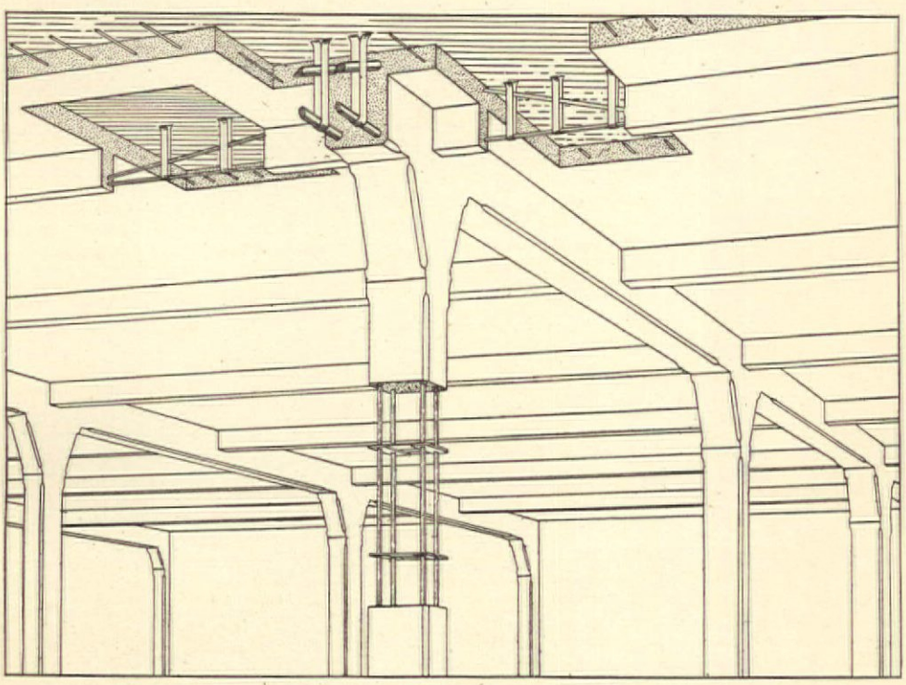

Fig. 12.

The girder (Fig. 5) which he has patented in all civilized countries of the world can hardly be improved. Its principle consists in embedding pairs of rods, in vertical planes, in the beam, one being always straight, the other bent upward near the supports, both being united by a number of bent straps, or stirrups.

The concrete, in connection with the steel rods, may be regarded as forming queen-post trusses, as shown separately in Figures 6 and 7; the place of the wood being taken by the concrete, and that of the verticals by the stirrups. These stirrups take up also the horizontal shearing-stresses, which are greatest at the ends near the neutral axis, and for this reason they are placed close together near the supports (Fig. 5).

Numerous tests, made by M. Hennebique, with girders with and without stirrups, showed the great gain in strength which results from their use.

It might be objected that we rely on the bond of the steel with the concrete; and that yet, in the most vital part of the beam, namely, in the centre, the concrete of the bottom flange will first fail when the beam is overloaded, and destroy the bond. This will surely happen; pieces of concrete may even drop out and lay the rods bare; but that is also where the real truss action of this combination commences, in which case we need the bond in the centre no longer; the steel rods will be strained in a much higher degree than before, the beam will very appreciably deflect, and at last failure of the beam will follow, either through breaking of the rods, through crushing of the concrete, or through simultaneous failure of both. But the dropping out of pieces of concrete long before half of the ultimate capacity of the beam is reached gives a timely warning, such as occurs neither with steel nor with wooden beams.

The theory of concrete-metal construction is at least as well known as that of steel beams; in fact, the successful builder in concrete-steel will guarantee his work with greater confidence than can the structural-steel works.

But economy and safety are attained only through scientific design, and the greatest calamities would follow if such structures were designed and built by so-called practical men.

One of the earliest applications of concrete-metal was in the construction of fireproof floors. Let us assume that we have to cover an area, $a\,b\,c\,d$ (Fig. 8), by a fireproof floor. In simple concrete floors we use steel beams, spaced 4 feet apart, and the whole is filled with concrete, as shown in section in Figure 9. It was soon found that these floors could carry a slightly greater load than that indicated for the beams alone, and that a more economical floor could be constructed by using T-sections instead of I-beams and placing them lower (Fig. 10). A similar floor was used in the building of the Citizens Savings and Loan Association in this city, only that T-sections of special shapes were employed. But M. Hennebique went farther. He substituted rods (Fig. 11) for the T's, a shape which is very easily procured in the market, and, especially to-day, at nearly half the cost of the T's. The girders, corresponding to

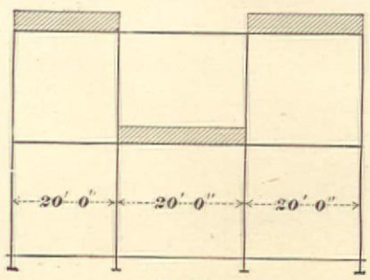

Fig. 13.

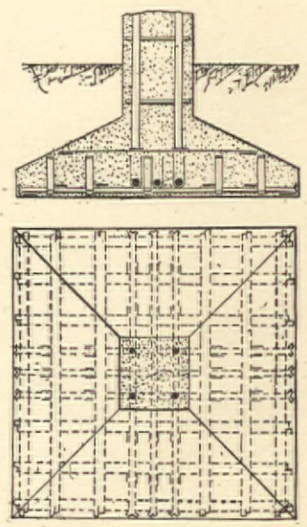

Fig. 14.

the steel beams in Figure 9, are substantially the same as shown in Figure 5. The slabs, between the girders, form a continuous beam, therefore tensile stresses are set up also above the girders. These are taken care of by horizontal rods at the bottoms of the slabs, and by bent rods approaching the top fibres over the supports. The whole floor forms the compression-flange of this composite girder, while the rods form the tension-flange; and the result is that we get a moment-of-inertia eighty to one hundred times greater than that of ordinary steel beams; and, as the ratio of the moduli of elasticity is only 1:15, we see that the Hennebique floors must be at least six times stiffer than steel girder floors.

In this connection I may cite a very interesting experiment made by the Engineering Department of the Orléans Railroad at the Austerlitz Station in Paris. A Hennebique floor, figured to carry a machinery load of 280 pounds per square foot, of a span of about 16 feet, was subjected, for a length of 17 feet, to a load of 420 pounds per square foot. The maximum deflection was $\frac{1}{8}$ inch, without any permanent set. In order to compare the resistance of this floor to shocks with that of steel-girder floors, this floor and a floor of the Quai d'Orsay station, built for the same purpose and of the same span, but consisting of I-beams and brick arches, were subjected to the blows of falling weights. The dead weight of the Hennebique floor was 60 pounds per square foot, that of the other 96 pounds per square foot. A weight of 110 pounds, falling from a height of $6\frac{1}{2}$ feet, produced, in the steel-and-brick floor, vibrations of an amplitude of $\frac{5}{32}$ inch, lasting two seconds, while a weight 220 pounds, falling from a height of 13 feet on the Hennebique floor, caused a maximum vibration of only $\frac{1}{32}$ of an inch, lasting $\frac{5}{7}$ of a second. Thus, twice the weight falling from twice the height caused only one-fifth of the deflection, with vibrations lasting only a third of the time.

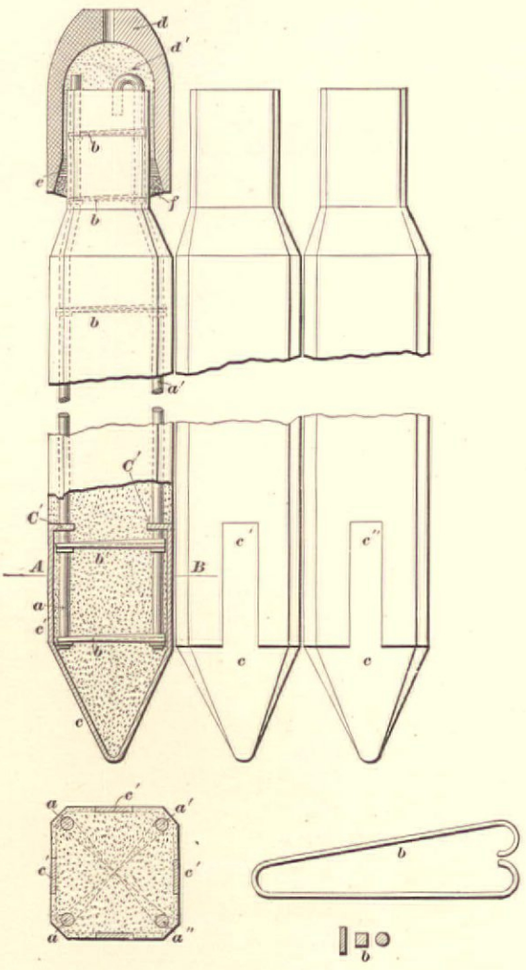

Fig. 15.

This is of enormous advantage in bridges, and especially in factory-buildings, not only because the lives of such structures are threatened by vibration, but also because freedom from vibration preserves the tools and makes better work possible.

The high price of steel, the long delays in deliveries of steel structural work, the difficulty (and often the impossibility) of securing economical sections, suggest the use of concrete-steel in the construction of wholly fireproof buildings.

Whether office-buildings, apartment-houses, residences or factories are to be built by the Hennebique system, the skeleton principle of construction is strictly followed.

If concrete walls are used they are strengthened by rods, and rarely exceed 6 inches in thickness. The columns consist of four or more rods, connected at short intervals by flat bars, and the whole is embedded in concrete. The rods (Fig. 12) are placed in the periphery only, thus giving the maximum radius of gyration and being in position to take any tensile stresses. The connections between the columns and the girders and beams are effected by ample brackets and are monolithic; and, as the floors are six times stiffer than steel-girder floors, the stresses, due to eccentric loading, are about one-sixth as great.[1] The columns can be so designed as to suit any exigency. Recesses can be formed for gas and water pipes and electric-wiring; brackets can be provided for transmission-shafts, electric travelling-cranes, etc. The diameters of these columns are only from 1 to 2 inches greater than those of steel columns without fireproofing; but for theatres and other architectural purposes they allow of a considerable reduction in width.

Hennebique columns were subjected to a severe test by the authorities of the last Paris Exhibition. The Palais de Costume was entirely built on the Hennebique system. The columns were 20 feet apart, and of such small diameter that the engineers doubted their resistance to eccentric loading, and applied a load of sand weighing 150 tons, or one and a half times the load for which the columns were calculated, in alternate panels of two stories (Fig. 13). The deflection of the columns could hardly be measured, and was a minute fraction of $\frac{1}{32}$ of an inch.

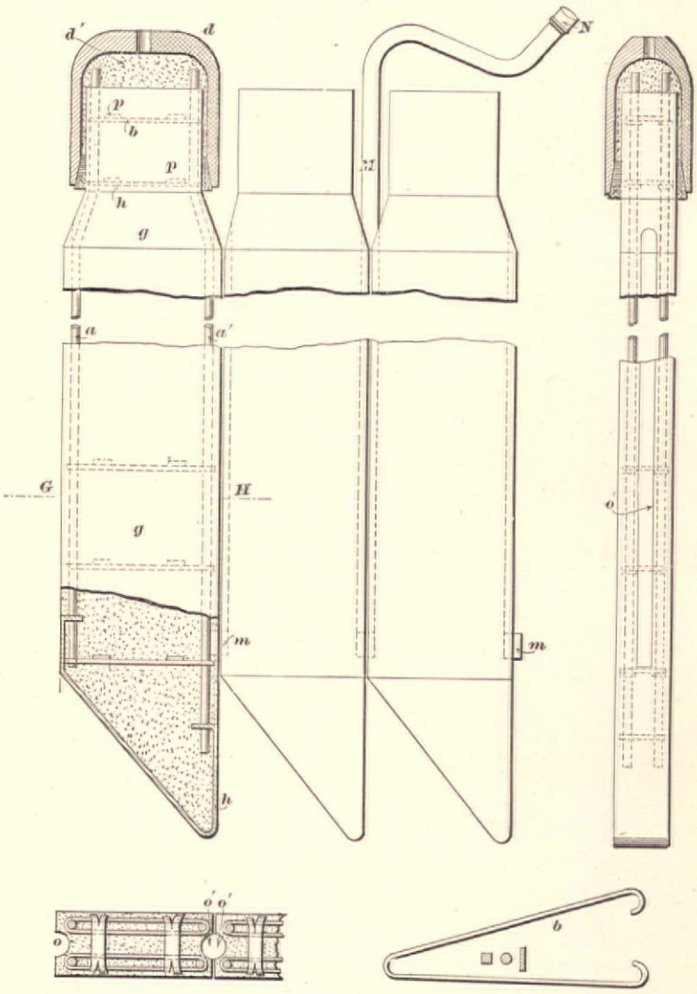

Fig 16.

A notable economy is obtained in the use of armored concrete for foundations. The ordinary methods heretofore in use can be described by saying that enormous masses of either concrete or steel beams were buried in the ground, making expensive excavations necessary, and cutting into the hard crust which generally overlies the yielding stratum. Hennebique's column-footings consist of a layer of concrete a few inches thick, in which are embedded steel rods in the two main directions (Fig. 14), and a monolithic truncated pyramid connected with the column they support. Such a footing may be considered a girder affected by uniformly distributed loads in an upward direction, and a nearly concentrated load acting downward in the centre. These forces tend to bend the pyramid in the two main directions, and this tendency is effectually resisted by the concrete in compression and by the rods in tension. The largest of these footings thus far constructed has a side of about 70 feet.

Where pile-driving is necessary concrete-steel piles are driven into the ground, and the columns are directly connected with them.

[1] See Handbook written by the author for Homan & Rodgers, London.

These piles are formed in moulds, and the concrete is strengthened by steel rods of suitable dimensions, connected at short intervals by stirrups (Fig. 15). At its lower end the pile is armed with a pointed shoe with side-plates, the ends of which are turned in, so as to lock the pile securely in place. The head of the pile is of less width than the body, allowing a clearance between the heads of two adjacent piles. In order to ensure uniform blows from the ram in the process of driving, and to prevent injury to the pile, the head is protected by a cap of cast steel and closed at its lower end by a clay ring held by a plug of hemp or spun yarn. The cap is previously filled with dried sand. A very regular cushion is thus formed on and all around the head, which cushion distributes the pressure in an absolutely uniform manner. This arrangement renders it permissible for the iron rods to project beyond the head of the pile, so that, in case of need, they may be connected with other parts of the structure or bent into hooks for convenience of handling.

The sheet-piles (Fig. 16) are strengthened by four rods, connected by wire clamps, which, in their turn, are cross-tied by flat-irons. At the lower end we have again a shoe, and the head is again of less width than the body, allowing room for the insertion of a cap. About 6 inches above the shoe on the longer of the narrow sides a projection, *m*, is formed, while the remainder of both narrow sides is grooved for the entire length. The projection on one of the piles slips into the groove of the next pile in ramming.

A special arrangement is provided to ensure the desired direction of driving. An iron pipe which fits the groove of the sheet-pile last driven, and that of the pile which is being driven, connects, by means of a hose, with a pump or water tank. This pipe serves also as guide, and the water forces out the sand which might jam the grooves, thus facilitating the driving of the pile. Once the pile is down to the desired depth, the pipe is withdrawn, cement is run between the grooves and a perfect water-tight joint and wall are established. Tongue-and-groove joints are also sometimes used.

These piles are somewhat more expensive than wooden ones, but are practically indestructible and of enormous resistance to bending. They are affected neither by the rise and fall of ground-water nor by sea-water, nor can they be attacked by teredos, which, in certain parts of the globe, destroy wooden piles in a very short time. What an ideal member in the construction of sea-walls, breakwaters, recreation piers, etc!

[To be continued.]

ROMAN AND ROMANESQUE FRANCE.[1] — IV.

ARLES.[2]

PLUTARCH, who gives a detailed account of the campaign of Marius in Gaul, 104–102 B. C., does not mention Arles; but in the "*Commentaries*" of Cæsar, and by other writers it is called a Roman colony of the Sixth Legion of Veterans; and it is probable that it was, after Narbonne, the most important place in that part of Gaul. Cæsar, during the siege of Marseilles, speaks of twelve vessels being built there (*naves longæ*) and armed ready for war in thirty days, so it must have been an important place with all the resources of a great city and shipyard. Honorius also, in a letter to Agricola, Prefect of Gaul, writes enthusiastically of the city, and of the crowds of merchants trading there; it was "the market of the world." In fact, "all the riches of the East, of fertile Africa, Arabia, Assyria, beautiful Spain and prolific Gaul . . . all send their produce . . . by sea and by land, in boats, in ships and in wagons." So, too, it was beloved of Constantine, and there his eldest son was born. It was from Arles that the Emperor started for his campaign against Maxentius, and it was during this journey to Rome that occurred the apparition of the luminous cross with the well-known legend: *In hoc signo vinces*. Moreover, the medals struck to commemorate the miracle, a hand holding a cross issuing from the clouds, had for the reverse the legend: *Aretas civitas*. After his victory over Maxentius, Constantine was baptized by Pope Sylvester, and, returning to Arles, he opened the celebrated Council in 314. It would be interesting to know where the Council was held, but history is silent upon the point. The Emperor embellished the city by erecting an Egyptian obelisk, and by decorating his palace with splendid colonnades and statues. He also constructed an aqueduct to supply the people with pure water from the mountains, and made Arles the political equal of Rome and Constantinople by establishing there the seat of the Governor of Gaul.

After the division of the Empire under Charlemagne, his son Charles became King of Arles and Provence. Charles le Chauve turned the city into a kingdom with a sovereign of its own, including Provence, Dauphiné, Orange, Bourgogne, Franche-Comté, Piémont, and Savoie as far as Genève. For 250 years it was governed by eleven kings succeeding Bozon, and then by consuls. Troubles succeeded; during which, in the eleventh century, the great church of S. Trophîme and its famous cloisters were commenced.

It is probably from this variety of ancestry, Greek, Roman, Gallic and, later on, Saracen, that the women of Arles have received their peculiar type of beauty — for there is no doubt that "*la belle Arlésienne*" is not a mere figure of speech. Their features are somewhat of the ancient Greek type — delicate straight noses, black velvety eyes, with faces of oval form. Their hair is generally dark brown, their complexions clear and pale. Some have olive complexions like the Italians — descendants, doubtless, of their Eastern ancestors. Others of Gallic origin are fair, with blue eyes and light hair. But the mass are dark-eyed with pale faces and beautifully chiselled features, holding themselves as if all the world belonged to them; grand creatures picturesquely clad, generally in black, with a *fichu* of lace over the shoulders gathered in at the waist; open necks with necklaces, and the quaint little *coiffure* on the top of a twist of hair. Such is the *belle Arlésienne* whom Bizet has immortalized; one can almost hear his music as they trip down the streets in the sunshine; and even when the icy mistral scuds round the corners like a whirlwind, they go on their way, nothing daunted, impervious alike to cold and its consequences, in spite of their uncovered necks.

Although the plain upon which the city is built is full of canals, rivers and dykes, it was far more so during the Roman period. The Rhone and the Durance spread their waters all over the country, and what are now shallow inland lagoons or marshes were then deep and navigable seas with innumerable islands. Montmajour and Les Baux, which are now hills rising from the plains, were then islands of a little archipelago; and Arles itself was connected with the sea by a series of navigable lagoons or canals.

The Amphitheatre suffered much from civic troubles. In the eighth century three square towers were erected for defensive purposes either by the Saracen Wali, of Narbonne, who obtained possession of Arles, or by Charles Martel, who expelled the Saracens in 739, the Amphitheatre itself being turned into a fortress, from which it degenerated into a small city of squalid hovels which remained until recent times. In an old print, the number of houses that were built into the colonnades may be seen, as well as several chapels; behind, to the left, is the tower of the cathedral, S. Trophîme.

Arles is full of fine portals and niches at the street-corners supporting figures of saints; and considering that the Roman theatre, the Cathedral, the cloisters and the Museum all deserve the most careful study, it is somewhat amusing to read in one's guide-book that the city "may be visited in a few hours." Why, one could spend a few hours in the Museum only, filled as it is with bas-reliefs, capitals, sarcophagi, and innumerable fragments telling of Roman splendor in the old days.

An interesting, though not a very beautiful, object is the water-pipe stamped with the name of the Roman plumber — *C. Canthius Porthinus fac.*, which was discovered in the bed of the river. Many of the sarcophagi, both Pagan and Early Christian, have been brought from the Aliscamps, the ancient cemetery (*Elisii Campi*), where the empty and uncovered tombs are witnesses of pillage and desecration. A few of them are sculptured on the sides with Early Christian or Roman designs, but the mass of those bearing any artistic value have been carried off by public authorities or private individuals.

One very interesting slab in the Museum deserves some description. It is called the *Miracles*. It is divided into seven compartments by stems of trees and foliage, and where the stems divide and form a sort of arch, a bird is placed. In the central division is the "Blessed Virgin," the clumsiest of all the figures. On the right we see "The Turning of the Water into Wine," "Restoring the Blind Man's Sight," and "Curing the Lame Man." On the left: "The Miracle of the Loaves and Fishes," "Healing the Sick Woman," "Raising the Dead." In each division Our Lord is depicted as the same short-haired youth, unbearded, which is uncommon, if not unique. The costumes are Roman; also the type of features and short hair of the Apostles; two or three of the heads recall the busts of Marcus Aurelius and Pliny. The persons upon whom the miracles are performed are of diminutive size.

Of the other sarcophagus, "The Miracle of the Loaves and Fishes," it will be noted that the faces are of the same type, and that the two Apostles holding respectively the basket of bread and the dish of fish are clean shaven, as represented on the first slab. The head of Christ is of a nobler type, with long curly hair, but still clean shaven, and recalling the type we associate with the young Siegfried, Gothic or Gallic.

"The Tomb of Phædra and Hyppolitus" is of finer workmanship, probably by a Greek sculptor, not of the best period. The drapery and some of the heads are fine, but the proportions of many of the limbs are incorrect. Above this is the noble fragment of a draped figure found on the Camargue, and a headless and armless "Victory" of beautiful form.

The entrance to the cloisters of S. Trophîme is an elegant pointed arch with graceful little columns of thirteenth-century workmanship. The cloisters are most ornate, and beautiful in the extreme, and are illustrative of architectural details of the twelfth to the fifteenth centuries. The older half is very rich in sculpture; on the outer face may be seen a bold specimen of dog-tooth ornament. Some of the capitals have a strong tendency towards Classical foliage. The first oratory at Arles was dedicated to S. Stephen, hence, his statue is placed by the side of that of S. Trophîme, the first Bishop in an important position. The west front of the Cathedral is a very fine example of Romanesque work, and owes its exquisite state of preservation to the hard material (marble) of which it is built.

It is characteristic of the compatriots of our old friend Tartarin that every one of whom one buys photographs has "les plus belles photographies d'Arles." You assure the man in the Museum that you have seen as fine elsewhere, that you have even bought some at two or three of the various stationers. "Ah, now," he retorts, with

[1] Continued from No. 1398, page 15.

[2] In this series of papers, I have purposely tried to steer clear of repeating what has already appeared in the *American Architect* upon the subject; consequently, much that is noteworthy in all the towns of Provence has been omitted. This applies also to the illustrations.

a patronizing air, "you mistake." (Madame and Monsieur are apparently superfluities in this part of France.) "Mine is the only complete collection." Then, you go round the corner to Mademoiselle ———, and she impresses upon you with her grandest manner that hers are unrivalled. "Assuredly it would be impossible to find the like in all the city." Nor are you contradicted in the most m· assured and polite terms; the whole air of the Arlesien is: "It is a privilege to buy of me; but if you would rather not, pray do not trouble about it." Some of them have courteous manners, but their characteristic style is roughness; indeed, my only and unique experience of rudeness in France, north and south, was at Arles, where I inadvertently walked into a church, to find a workshop and its owner, who reproved me, to put it mildly, in most unmannerly language for not perceiving the board: *Defence d'entrer*. Churches usually are for the use of the public; but S. Césaire is a workshop and coach-house for hearses. Many are the desecrated churches in the dead cities of Southern France. S. BEALE.

A SEARCH FOR THE TIBER'S TREASURES.

PROF. CIRO NISPI-LANDI, the author of the latest scheme for exploring the bed of the river Tiber, is no mere "dreamer." A man of profound learning, he now holds the responsible position of inspector of the national monuments to the Italian Government, and is the author of several thoughtful works on ancient Rome. It was the Professor's historical studies and researches that inspired him with his great idea of searching the Tiber for treasures. They directed his attention first to the length of time during which Romans, rich and poor alike, cast into the slow-flowing river their most cherished possessions, and also to the period, unexampled in history, of thirty-four centuries in which the Tiber was the centre of momentous events. Professor Nispi-Landi's notions were strengthened by what he saw while in charge, several years ago, of the work of building the Tiber's embankment. The Professor noticed, as he tells me, that "whenever and wherever the Tiber was searched in the course of bridge-building or of the work on the embankment, ancient and valuable things always came to light." Generally they were valuable enough to pay the entire cost of the operations. For instance, one Italian bridge-building firm, in laying the two pillars of the Ponte Palatino, discovered antiquities to the value of several million lire. In adjusting the foundation-pillar of the Ponte Garibaldi three beautiful antique bronze statues, one of Bacchus and one of Venus, came to light, and in widening the Ponte Cestio antique jewelry, one piece of which was a wonderful gold collar of turquoise, and other valuable relics were drawn up from the depths where they had lain for years. In the course of the complete work on the embankment enough ancient works of art and other relics were discovered to stock one of the richest museums in Rome, that of the Baths of Diocletian.

"Most of the treasures," remarked the Professor, in response to one of my questions, "are certainly to be found in the most central part of the river, and have remained undiscovered for that very reason." He consented to give a hint of his plans. He has, for this purpose, divided the Tiber into "zones," or districts. They are eleven in number, No. 1 covering most of the Tiber in Rome proper, the others the course of the river outside the Eternal City. "We shall proceed," said the Professor, "by digging parallel trenches for the first zone, where the ancient source of the river is dried up, with the aid of steam-pumps, and where the Tiberine waters follow their natural course with pneumatic tanks modified and adapted to the special use of river exploration." The enterprise will be financed by Chevalier William Millar, a wealthy Anglo-Italian of Leghorn, who has implicit confidence in the savant's scheme. Just when the actual work will be begun is not yet decided. The permission of the State was given to the enterprise some time ago, but recently some "recommendations" have been made by the museum of antiquities. Compliance with them has delayed matters, and it may be some time before the delving begins in earnest.

Search in the Tiber always has been richly rewarded. The Professor goes back as far as the thirteenth century, quoting one of its historians, Falminio Vacca, who described how, a small boat having sunk near the Ponte Sublicio and several swimmers being engaged to fish it out, arrows, swords, breastplates, arms of every description, "and other beautiful objects" recognized as purely Etruscan, were discovered and brought to the surface. But, after all, it is necessary only to review one's Roman history a little to convince any one that there should be riches in the Tiber. That they were put in is certain, and Professor Nispi-Landi states that in all his research he has been unable to find any record of any large quantities of them having been taken out. The records of sacrifices to the Tibertine deity go back to the beginnings of Roman history. Even Virgil tells how Æneas promised Father Tiber that if he would protect him from peril, "Thou shalt ever be worshipped by me with homage and with gifts." The example of Æneas was followed by the generations that came after him. Sacrifices were made on the eve of great events, such as battles, during times of national peril, to make sure of having the god on the suppliant's side, during great rejoicings, and to commemorate illustrious men who had died. These were the great public sacrifices, of course, but private individuals in prosperity and grief offered personally similar sacrifices, generally the most precious things they owned. Back in the time of the Arcadians, men used to be hurled into the Tiber, but soon they were replaced by puppets and graven images, and after this the offerings of money, jewelry and precious things began.

It was not only the Romans who sacrificed to Father Tiber. The superstitions of all the Southern races seem to have been pretty much alike at this time, and whatever force was near the river made votive offerings to it. The Huns, the Goths and the Vandals all hurled a large part of the plunder derived from their sacks of Rome into the ancient stream. "Such offerings were," says Professor Nispi-Landi, "the cause which contributed chiefly and for the longest period to enrich the bed of the Tiber with precious relics." Another cause, however, was the casting into the stream by the Romans of their possessions in order to prevent their being captured by enemies. For instance, after the defeat of Maxentius Saxa by Constantine, say the records, "Not only a great number of dead and wounded men and an immense quantity of arms and valuable objects, but even the treasures of Maxentius and the military chest of his army were thrown into the river to prevent their falling into the hands of the victorious foe." To save them from the Huns, and, later on, from the French, marbles, bronzes, statues, busts and costly images enriched the Tiber. Add to all this treasure the hundreds of rich Pagan statues and temple ornaments thrown into the river by the Christians, and the property of all who conspired to bring about the assassination of Cæsar, which had a similar fate, and an idea will begin to form of the vast treasures on the Tiber's bottom.

This Italian scholar, whose works, "*Rome before Humanity*" and *M. Agrippa and his Temple*," are, by the way, well known in Italy, has not by any means contented himself with the conviction that treasures in the aggregate are below Tiber waters. He has drawn up for himself a list of individual relics of which history speaks, and has attempted to locate each in one of his "zones," according to the details which he has been able to gather as to its sacrifice. For instance, the Professor believes that the sacred candlestick of Moses, the object that he would like best of all to recover, will be found in its first zone, or in that part of the Tiber near the famous Castel Angelo, close to the Vatican and St. Peter's, probably that part of the river that most Americans have seen.

Says the Professor: "It is certain that religious objects were left untouched by the superstitious Alaric and Genseric; indeed, in 509 and 529 the candlestick was still to be seen in Rome. I regard it as certain that the emblem ordered on Mount Sinai, which stood in the Tabernacle of King David, which was carried round the walls of Jericho and was venerated by Cæsar and Pompey, was eventually lowered by the Jews down from the bow of Esculapius's ship on Tibertine Island in our first zone. The Jews themselves always have asserted that it is there. Consider that more than 1,900 years have passed since then, and that the candlestick was then about 1,550 years old, making a total of 3,448 years! What importance would its discovery have? Who should have the greatest claim to its possession? How much should be paid to the discoverers? It is not easy to answer these questions. Everything should be as wonderful as the candlestick itself."

Professor Nispi-Landi will be one of the most disappointed men in the world if he does not bring up from the Tiber's bed thousands of suits of rich armor, of swords and shields, the property of the wounded men who through custom were hurled into the river and those that fell in the fearful battles on the bridges. Among these he expects will be the armor of brave old Horatius Cocles and his men, who kept the Pons Sublicius against the Etruscan army and finally leaped into the Tiber. "There must be," he writes, "in that part of the river arms, coins, ornaments, jewels, such as buckles, collars and rings, all rare and valuable as the only relics of the Romans and Etruscans of those days." He expects to find the famous Minerva statue of Phidias, as well as those of Hercules, Mars and Venus, with the pearl of Cleopatra. He believes he will bring to light the solid gold statue of Claudius II, which once stood in the Capitol and which was thrown into the Tiber to save it from the Goths.

Probably one of the first questions that will come into the mind of any one who reads this story of Professor Nispi-Landi's great project will be: If the Tiber is so rich in treasures, why has no one tried to get them before, or at least why has no one thought of doing so? Well, for hundreds of years men of an ingenious turn of mind have been pondering upon doing and attempting to do that precise thing. For his scheme of searching the Tiber's bed, Professor Nispi-Landi claims no originality; he claims only to be the first man who has yet set doing it with the proper mechanical devices. The list of those who in modern times have attempted to make the Tiber disgorge is headed by the name of the learned Cardinal de Polignac, who planned to deviate the Tiber from its course for about two miles, and then to dig for the antiquities which he believed were discoverable. Pope Benedict XIV smiled on the Cardinal's project, but while the necessary capital was being gathered the Pope died, and his successor was dissuaded from aiding De Polignac, on the ground that the climate of Rome might be injured.

In 1773, Don Alfonzo Bruzzi undertook the exploration of the Tiber by means of a cofferdam of his own invention. The device did not come up to expectation, for the water rose and overturned it. Yet, for the short time it worked, enough was found to pay all costs and leave a profit. The scheme of Joseph Naro, in 1815, was not so successful. He, too, believed the Tiber to contain treasure, but he tried to get it by means of a kind of mud-scraper, a "grattina," as he called it, which, whenever an incumbrance was met, was planned to strap it and draw it up. Only fragments of statues, marble blocks and funeral columns were, however, brought up by the

"grattina." Garibaldi dreamed of searching the Tiber, but he, too, wished to deviate the course of the river, and this the Italian Parliament refused to allow. The most recent man of celebrity to consider exploring the Tiber was the late Prince Alexander Torlonia. He, however, wanted to keep so much of what he found that the Government refused to grant him permission to make a trial. The Prince had felt so certain of success that he offered to deposit as a guaranty for the work the sum of a million and a half of lire, $300,000.

Professor Nispi-Landi believes that he at last will succeed. He says: "I have now fulfilled all the formalities required by the Minister of Public Works, and the ministerial decree will enable us, with new means and a positive and practical prospectus, to see the great river searched at last, and the abundant riches of intrinsic and artistic value of every ancient epoch triumphantly recovered. Let only fortune smile on our enterprise and merit and riches are ours!" — *London Correspondence of the Springfield Republican.*

NOTES AND CLIPPINGS

PETERBOROUGH CATHEDRAL'S WEST FRONT. — The restoration of Peterborough Cathedral has been completed, the scaffolding has been removed from the west front, and "the finest portico in Europe," as Ruskin styled it, is once more revealed in all its beauty. The walls have been most effectually secured, and the gables rebuilt where necessary, the old stones being used. It is 18 years since the restoration-work was begun; it has been carried out at a cost of $400,000. — *N. Y. Evening Post.*

RIGHT TO USE FLUES IN A PARTY-WALL. — Between the two buildings at 853 and 851 Lafayette Avenue, Brooklyn, there is a party-wall 12 inches thick. The building at No. 853 was erected first, and the flues in it extend 2 inches beyond the centre-line of the party-wall. When the adjoining building was constructed, flues for it were provided in the wall on the other side. A Mr. McKnight, the original owner of both buildings, sold No. 853 to Simon Batt before he built No. 851. The latter building he sold to Adelaide Kelly. Her attempt to cut into the flues in the party-wall was restrained by an injunction, and the action of the Supreme Court in doing so has been upheld by the Second Appellate Division. The cutting into the flues by the defendant caused the plaintiff's house to fill with smoke. Mrs. Kelly's contention was that, inasmuch as the flues extend 2 inches into her half of the party-wall, she could lawfully connect with them. A case cited by her counsel recognizing the principle that where flues are constructed in a party-wall for the common use of the contiguous buildings and accessible to either, they may be used by either, and another case where flues were built in a party-wall for the use of both houses, cannot be used, said Justice Hirschberg, for the Appellate Court, as authority to confer an easement upon one owner to use flues designed for the other owner where independent provision has been made for the former, and the use would be detrimental to the latter's enjoyment of his unquestioned rights. — *N. Y. Times.*

PROF. MCGEE AND THE AMERICAN INTERNATIONAL ARCHÆOLOGICAL COMMISSION. — Prof. J. W. McGee, of the Bureau of American Ethnology, one of the best-known scientists in the country, has been appointed by the President, through the Secretary of State, to represent the United States on the American International Archæological Commission, whose creation was recommended by the second International Conference of American States held in Mexico last winter. Each of the American Republics will appoint one or more members of the Commission, appointments to be for five years. Each Government interested will contribute to the expenses of the Commission on the same basis as that on which the Bureau of American Republics is supported. The idea of the Commission is to preserve the ruins of the principal prehistoric cities, establishing at each of them a museum to contain objects of interest found in the locality, and at such exhumed cities to establish conveniences for the visiting public. It will be the effort of the Commission to establish an American international museum in the city selected by the majority of the Republics participating in the work of the Commission which shall become the centre of all American archæological investigations and interpretations. — *Exchange.*

RIGHT TO LIGHT AND AIR. — In the case of Stevens *vs.* Salomon, Justice Steckler granted an injunction restraining the defendant, who was erecting an extension to the rear of the building 19 West Forty-second Street, thereby shutting off light and air from the windows. The plaintiff was a tenant of the building before it was purchased by the defendant in August last. Salomon collected rent for September and October, and in the latter month leased the premises to plaintiff for three years and six months from November 1. Justice Steckler said in part: "When the lease was made there was no structure in the yard interfering with the light and air coming into plaintiff's rear room. Although it does not appear that the plaintiff had a right of access to the yard, the light passing into the windows from the yard was essential to the beneficial use of the premises. The evidence establishes that at the time the lease was made it was the intention of the parties that plaintiff should have such use of the premises. To the extent of the light and air coming from the yard into the rear room the plaintiff was therefore entitled to an easement in the yard, and an attempt to change the condition of affairs to her detriment may be defeated by an injunction." — *N. Y. Times.*

TAKING DOWN A STEEL CHIMNEY. — The tallest steel chimney in New York was recently torn down. The stack, which was 18 feet in circumference, consisted of thirty sections, each weighing a ton. In taking down the chimney the workmen rigged up a scaffold about 10 feet from the top. Perched upon this support, they punched out the rivets that held the adjacent sections together, and lowered the two sections, weighing two tons, by ropes connected with windlasses. The scaffold was then lowered to the next two sections, where the disjointing work was continued. The removal of the chimney was effected at a cost of about $2,000. — *Boston Transcript.*

ITALIAN STREET-BOYS AND ARCHITECTURE. — The façade of a beautiful old church in Siena has been seriously defaced by boys, who discovered that sparks were emitted when they threw stones at the marble. When some French visitors protested last winter to the guardians of the church, it was said that the sport could not be interfered with, because for generations the boys of the town had been accustomed to amuse themselves at night in this manner. Three of the ancient windows in the Church of St. Etienne du Mont in Paris have been broken by boys throwing stones at them. — *N. Y. Evening Post.*

THE EPHESIAN FINDS. — "The more important 'finds' made by the Austrian archæologists in Ephesus," says the *Athenæum*, "are temporarily lodged for exhibition in the 'Tempel' of the Vienna Volksgarten. The latest of these is a rediscovered masterpiece of Greek sculpture which originally stood in the splendid market-place of Ephesus. It represents a boy of two or three years old, sitting upon the ground and holding a duck with his left hand, and is supposed to have been a companion work to the 'Boy with the Goose,' by the sculptor Boëthus of Chalcedon, which was praised by Cicero and Pliny, but is only known through later copies."

SUCCESS OF THE TURIN EXHIBITION. — The London *Times* correspondent at Rome says that the exhibition of modern decorative art at Turin closed November 15. The financial and artistic success of the exhibition, the correspondent observes, may be said to prove that what is known as the "new art" has taken firm root, and, having shaken off the grotesque and fantastic excrescences which marred its inception, is developing along lines assuring a future industrially successful and æsthetically wholesome. Incidentally, says the correspondent, the exhibition raises the question whether one of the effects of the huge modern fortunes may not be to create, especially in the United States, conditions under which masterpieces equal to the classic models may again be produced.

BRONZE HOUSEHOLD GODS OF THE JEWS. — The Musée Guimet, in Paris, the great storehouse of materials for the study of the history of religions, has received from the traveller Dinghello, now engaged in archæological work in Palestine, a number of recently discovered bronze images which, no doubt, are specimens of the household gods of the Jews so often mentioned in the Old Testament, but of which none had ever before been found. They show undoubted Semitic features. There are a Baal and an Astarte with plaited hair, the latter with a crown. The height of these images is 37 centimetres. — *Exchange.*

NOTES AND CLIPPINGS. 79

THE New York *Evening Post* has a rather startling editorial upon the frauds practised upon rich American amateurs of works of art. Dr. Bode, the Director of the Berlin Museum, furnishes some of the material for this editorial, in an article in the new German artistic periodical, *Kunst und Künstler*, in which he traces the early history of some of the gems which now enrich great American collections; but the *Evening Post* has some information of its own to add, which goes to show that American amateurs of the present day, although richer than those of the last generation, and, as a rule, more familiar with works of art, are still unmercifully fleeced by the dealers and agents in Europe in whom they confide. As an example, the recent purchase of the Massarenti collection, in Rome, by Mr. Walters, of Baltimore, is mentioned. The *Evening Post* has a story to tell about this transaction which, for the present, it keeps to itself; but it justifies the warning which it gave when the collection was first offered for sale to Mr. Walters by quoting from Dr. Bode, who says that, "Whoever, like myself, has had the pleasure of seeing this collection knows that it would be difficult to name a second that is so void of good things, and contains so many mediocre pictures, and forgeries of great names." He adds that the Italian Government assessed a twenty per cent export tax of forty thousand francs on the collection, indicating that its experts valued it at two hundred thousand francs, or less than forty thousand dollars. The Italian appraisers were not likely to undervalue intentionally a collection of pictures to be shipped out of the country to an American purchaser; yet Mr. Walters is said to have paid five million francs for it, although, as Dr. Bode says, it "does not contain one noteworthy picture, one remarkable statue, or half a dozen works of a respectable mediocrity." It should be said that it does not follow from all this that Mr. Walters, who was brought up from childhood among the works of art collected by his father, one of the most discriminating amateurs that America ever produced, was deceived in his purchase. It is quite likely that he may have been imposed upon in the case of individual works, but if, as has been alleged, nearly all the experts and connoisseurs in Europe have for a hundred years been admiring, in the Sistine Madonna at Dresden, a copy, instead of an original Raphael, an amateur can hardly be expected to pass at first sight upon the genuineness of every work in a large collection; and it is much more likely that Mr. Walters was quite aware that the pictures were not of the first merit, but, knowing that pictures of the first merit of the Italian school are absolutely unattainable, and that works of the second merit will soon be equally so, he decided to take what he could get, and to pay what was demanded for it, rather than go without it. Nearly all our great museums have been glad to get specimens of Titian, or Rubens, or Rembrandt which would make but a sorry figure in the Salon Carré of the Louvre, but which, for all that, are priceless in America, as examples to students of the methods of the great painters. In the same way, although it is probably true that the Raphael recently purchased by Mr. Morgan has been offered to the European museums for a much smaller sum than Mr. Morgan paid for it, and refused, it does not follow that any amateur would ever have been able to buy it for the price which would have been accepted from a museum, or that, while it would probably be eclipsed by the Ansidei Madonna, on the Belle Jardinière, or the Madonna della Seggiola, it may not be of inestimable value to artists and the public in this country as the only available example of the one painter of the world in whose perfect art there is not a single false note.

ALTHOUGH men so thoroughly familiar with good art as Mr. Morgan and Mr. Walters, while they may be willing to pay high prices for inferior specimens, if these specimens are the best to be had, and cannot be purchased for any less, are not likely to be grossly deceived in what they are buying, it must be acknowledged that a great deal of trickery is practised upon American amateurs of less discrimination; and the *Evening Post* is justified in its desire that some method might be devised for equipping rich people who wish to buy pictures with the knowledge requisite for escaping deception. Unfortunately, our millionaires cannot often afford the time necessary for studying antique sculpture and cinque-cento painting, to say nothing of the lack of examples here to study; but we might suggest that it is always within the power of amateurs to observe the beauties of nature, and a person, particularly a person of the American race, the most sensitive of any to beauty, who follows his own instinct, cultivated by the observation of American sunset and sunrise skies, morning mists, flowers, and the faces and forms of young and innocent Americans, without allowing himself to be led astray by famous names, will not often be grossly deceived. If there is anything which impresses itself particularly upon the student of painting, it is that no one but a great artist can paint a beautiful face, as Americans understand beauty. The beauty may be of a superficial kind, like that of Greuze's smiling, pink-cheeked damsels, or it may be the ineffable purity and love of the Sistine Madonna, or of the Pre-Raphaelite saints and angels; but the amateur, particularly the American amateur, may be quite sure that if he sees in a picture a face that charms and touches him, the picture is worth buying, whatever may be the name appended to it; and, on the contrary, if the faces in a picture which he is asked to buy do not positively attract him, he had better let the picture alone, whoever may be its reputed author. It is true that there is often some quality in figure-painting which may give it value, independent of the beauty of the faces, as, for example, the color-effects in the curious daubs of Monticelli, or the tricks of chiaroscuro of some of the inferior Italians; but these qualities are easily copied, so that an amateur capable of appreciating them could not, without life-long study of details of touch, be sure of the genuineness of such pictures; while a beautiful face can never be copied, or, at least, can be copied only by an artist of as great power as the one who originally painted it. A painter of inferior capacity, whether he copies, or paints from nature, or from his own inspiration, can never get rid of the woodenness, or the theatrical exaggeration, or the affected simper which is in his own mind, and which, in spite of him, shows itself in his work. When he can get the affectation and insincerity out of his own mind, he can get it out of his painting, but not until then; and the man who can paint with absolute truth, either to nature or to his own ideal, is already great.

EVEN in figure-painting, the American eye, when unprejudiced by theories or fashions, is singularly correct in its judgment. It would be far too much to say that great artists have always led moral lives, or that morality alone can make a great artist; but we believe that most painters will say that no one who does not keep in his soul some little sanctuary of purity can paint the figure, particularly the nude, as the great artists paint it; and Americans, who are still preëminent in continence above all other civilized people, are, for that reason, quick to discover the apathetic indifference, the affectation, or, worst of all, the venomous brutality, with which the cold-blooded, the hypocritical or the degraded artist inevitably treats what to a great painter or sculptor is the incarnation of love.

IN regard to landscape-painting, it is much more difficult for the amateur to escape imposition than in figure-painting, but even here Americans, if they will forget all about schools, and pay no attention to the names signed on the pictures, are capable of excellent judgment. It would hardly be too much to say that American collectors were the first to discover the merits of the Barbizon School of French landscape painters. Corot was still neglected in France when American amateurs began buying his pictures, and many of the most beautiful pictures of Rousseau, Daubigny, Diaz, Corot, Ziem and others of the modern French school of landscape-painting were brought to America before their authors had become famous in France. This seems to have been the result of the greater quickness of Americans, sensitive by nature to landscape beauty, and indifferent to the artistic traditions and prejudices of the old world, to appreciate the truth of the new work; and the same instinct may be relied upon by the amateur to a much greater extent than is generally supposed. If he is careful not to put into a picture, from his own imagination, what is not really there, a form of self-deception which is not uncommon, the cultivated American, accustomed to feel the sentiment of actual landscape, can easily pick out of a dealer's or an auction-room collection the pictures which inspire in him the sentiment of the real scene. There are not likely to be many of them in an average collection, but those that do fulfil this condition are tolerably sure to be the work of great artists. Some of the artists may be young, and still unknown to fame, but their pictures may still be bought with confidence that the talent which produced them will meet with its reward in due time.

MR. JOSEPH M. WILSON, of Philadelphia, of the noted firm of Wilson Brothers, equally distinguished as an architect and engineer, died suddenly in his office a few days ago. Mr. Wilson was born in Phœnixville, Pa., sixty-four years ago, his father being an engineer of great distinction. Young Wilson graduated as a civil engineer at the Rensselaer Polytechnic Institute of Troy, N. Y., and after devoting himself for a short time to the study of analytic chemistry, took up engineering again in the service of the Pennsylvania Railroad Company. He was rapidly promoted, and, a few years later, was made "Engineer of Bridges and Buildings" to the Company. In 1873, he entered the competition for the buildings of the Centennial Exhibition in Philadelphia, in association with John McArthur, Jr., and was one of the ten architects selected for the work, the Main Exhibition Building and the Machinery Hall being entrusted to him, jointly with Henry Pettit. Although so much engaged in outside work, Mr. Wilson was still retained in the service of the Pennsylvania Railroad Company, and continued his connection with it for many years after the firm which he established with his brother, for engineering and architectural work, had grown famous. Naturally, much of Mr. Wilson's work in architecture was carried out for the Pennsylvania Railroad Company, for which he built the Broad Street Station, in Philadelphia, and many smaller ones; but he also designed, in connection, we believe, with Mr. Kimball, the Philadelphia and Reading Station, in Philadelphia, and was the architect of the Drexel Building, in Philadelphia, the Drexel Institute, the Presbyterian Hospital, and many other noted structures.

A NEW element has been introduced into the discussion over improvements in the New York Court-house by the declaration of Justice Truax, of the Supreme Court, Chairman of the Justices' Committee on court-house improvements, that it is impracticable to alter the present building by adding stories, in the way which has been suggested by the Municipal Art Society, so as to make it acceptable to the justices; and that, if the building cannot be extended on the ground, which is opposed by the Municipal Art Society, as well as by all those who interest themselves in the preservation of the Park, it would be best to abandon it, and build a new and modern court-house at least as far up town as Twenty-sixth Street. There is, apparently, no reason why this suggestion should not be carried out, to the advantage of the courts, which would find in the neighborhood of Madison Square better air and light, and less noise, than on Chambers Street, and also to the advantage of the City-hall Park, from which the old building could be cleared away. Some of the newspapers express the fear that the removal of the court-house from the Park would be inconvenient for lawyers, many of whom have offices in lower Broadway; but most lawyers care very little about being near the court-house, proximity to their clients being with them a much more important consideration. In fact, very many eminent lawyers never go into a court-house, devoting their time entirely to consultations, and leaving to assistants or junior partners the care of filing papers and conducting cases. This is especially true of New York, and, if the court-house should be moved to Madison Square, very few legal firms would think of following it.

THE city of New York is likely to be made, in time, as safe against fire as Vienna, if official action can bring about that result. Notice has already been given that the storage, sale and use of parlor matches in the city will be prohibited after January 1, next; and it is quite likely that the use of gasolene may be next regulated; and, in another branch of official activity, Commissioner Stewart, of the Department of Buildings, has been vigorously enforcing the law in regard to the use of fireproofed wood in lofty structures, more than one hundred thousand feet of this material, which had been tested by the department experts, and found defective, having been rejected in a single week.

IT is astonishing that a city like London should think of building, or, rather, of rebuilding, a great bridge without the aid of a trained artist. The Tower Bridge, although the architect who designed it was an official, known more for his amiability and business talent than as an artist, meets with considerable cleverness and success a very difficult artistic problem; and the Vauxhall Bridge is not only more conspicuous, but lends itself far better than the Tower Bridge to artistic treatment. In Paris, where all the permanent bridges, except the railway viaduct, are beautiful, and the last, the Alexander Third Bridge, is one of the most masterly examples of metal-work design in existence, or in St. Petersburg, where designs for two bridges have lately been thrown open to competition among architects of all nations, or in New York, where designs for new bridges must not only be made under the supervision of the very accomplished architect attached to the Bridge Commission, but must receive the approval of the Art Commission, the idea of giving an engineer license to indulge his notions of the "Gothic" style in cast iron in one of the most conspicuous bridges in the city would be received with universal protest; and it is strange that London should be contented with what the Muscovites and the Yankees repudiate. Even Boston, which possesses few bridges, and those of a very inconspicuous character, has been careful to commission an architect to advise in the design of a simple "rapid transit" bridge; while its park bridges, some of which are of considerable importance as engineering structures, are models of variety and beauty, having been designed by different architects, selected for the purpose. As for the cities of a more ancient civilization it is interesting to imagine what the Florentines of the Renaissance would have thought of a scheme for putting an iron bridge, designed in engineers' Gothic, across the Arno, or what the Romans would have said to such a proposition. The city of London is so rich that it is reproached with the recklessness with which it spends money on objects of doubtful utility, and it can certainly afford to devote some thought, if not money, to the agreeable appearance of one of the most conspicuous objects in the Metropolitan District.

THE Royal Institute of British Architects has petitioned the London County Council to join an architect with the engineer of the new bridge which is intended to replace Vauxhall Bridge. Apparently, the designs for the proposed structure have been prepared exclusively by an engineer, who has conceived them in what he imagines to be the "Gothic" style. They have, through the courtesy of the officials, been examined by the Council of the Institute, and architects will be quite ready to believe that the Council puts the case mildly when it says that, if they are carried into execution, the bridge will be a "discredit" to the art of the century. The Council represents, in colors none too strong, the importance of giving to a monument so conspicuous as a great bridge an artistic character; and, while expressing its wish that engineering exigencies might permit the erection of a bridge all of stone, it says that even one of iron and stone can, and should, be artistically designed.

THE HENNEBIQUE SYSTEM OF ARMORED-CONCRETE CONSTRUCTION.[1] — II.

I HAVE now described in particular the different elements which compose a building designed on the Hennebique system; but it yet remains to prove their resistance to fire. Of the many tests which M. Hennebique and various European Governments have made on buildings of his design, I will describe the fire-test of a two-story pavilion

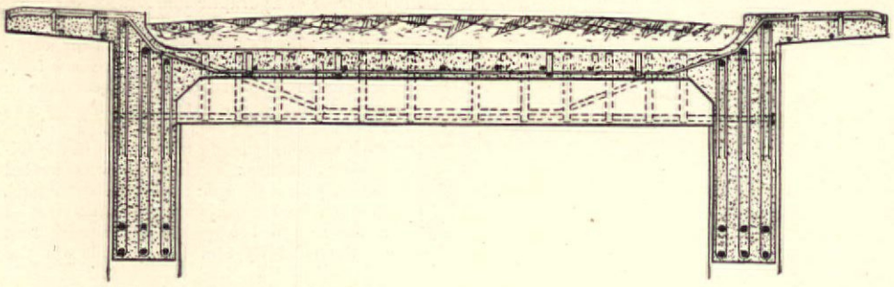

Fig. 17. Cross Section of a Bridge.

at the Exhibition of Ghent, in Belgium, in 1899. This pavilion, measuring 20′ x 15′, was built entirely of ferro-concrete, and the windows and doors were provided with Siemens wire-glass. In all, two tests were made. In the first test the second floor was loaded with 300 pounds per square foot, or one and a half times the load for which it was designed, and a deflection of $\frac{1}{8000}$ of the span was produced. On September 9 the lower room was filled with about 220 cubic feet of wood and coal. This material was sprinkled with petroleum and set on fire. The conflagration lasted one hour, and produced a temperature of about 1,300 degrees Fahr. The walls were red hot on the inside; yet, notwithstanding that their thickness was only $4\frac{3}{4}$ inches, the hand could easily be held on the outside without experiencing any discomfort.

The temperature of the second floor increased only 4 degrees, which means that no mercantile product whatsoever would have suffered damage. The deflection of the floor increased to $\frac{9}{16}$ of an inch, but two hours after the extinction of the fire was diminished by $\frac{1}{8}$ an inch, so that under a very heavy load the permanent deflection resulting from the fire was scarcely perceptible.

In order to prove that an armored-concrete floor which had been subjected to fire was still capable of bearing the same loads as before, M. Hennebique made a new test on September 28; this time loading the floor with 400 pounds per square foot, or double its intended load. When the 300 pounds mark was reached the deflection was found to be precisely the same as before the first test. At 400 pounds per square foot the deflection was only $\frac{1}{8}$ of an inch.

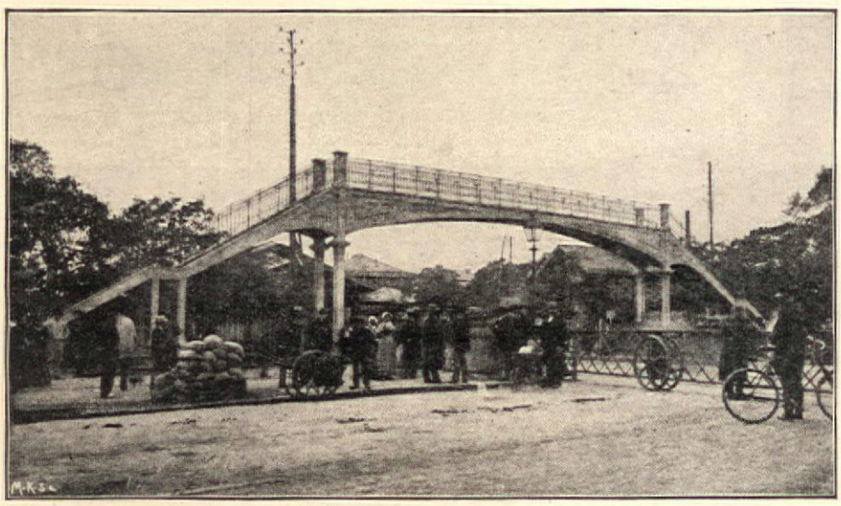

Fig. 19. Footbridge over Railroad, Lorient, France.

The lower room was completely filled with wood and coal, the upper room partially filled with the same materials, and the roof was loaded with 200 pounds per square foot. At six minutes past four the fire was lighted on both piles and lasted until half-past six. The fire played so fiercely against the sides and ceiling that the plastering of the latter was calcined, and the wire-glass of the windows and doors melted.

The building was momentarily forced out of shape (expanded), but showed no cracks and only very fine fissures, which in no case let the hot air escape. Again the contact of the hand with the outside of the walls could easily be endured. The deflection of the second floor reached a maximum of $\frac{3}{4}$ inch at twenty minutes to six; after this time no further increase could be observed.

At half-past six, when, after continual firing, no change in the state of the building could be detected, the commission agreed to extinguish the fire, which was done by directing a stream of water from a hose against the walls and ceiling and afterward against the coal-piles.

When, on the following day, the fire-authorities examined the building, it was found that the conflagration had not injured the general structure in any way. There was no permanent set in the floors and the few fissures caused by the expansion were completely closed. A series of pyrometers indicated a temperature of 2,200 degrees Fahr.

Lime-kilns, constructed entirely of concrete, dispensing with fire-bricks and steel shell, have endured for years a temperature of 2,200 degrees to 2,500 degrees Fahr.

From every point-of-view armored-concrete buildings are superior to those of any other type. They are monolithic; settlement of the ground is properly transferred and equalized by means of their enormous stiffness; they consist of practically one material, and variation of temperature cannot produce unsightly cracks; they become stronger with age, concrete forming an artificial stone better than the best stone which ever came from a quarry; the buildings are cool in summer and warm in winter.

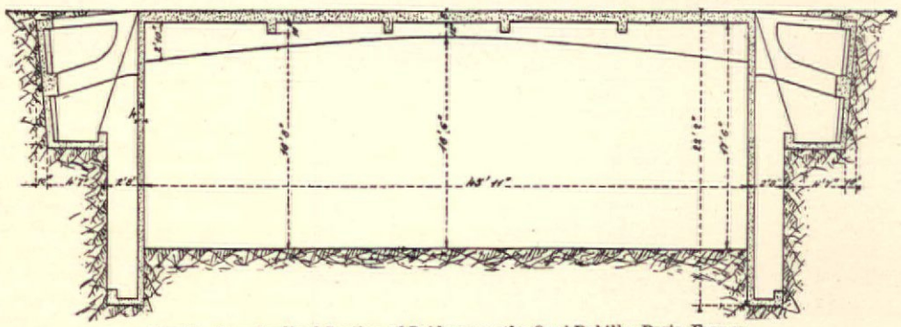

Fig. 18. Longitudinal Section of Bridge over the Quai Debilly, Paris, France.

Considering, moreover, the facility with which the materials can be procured, so that only a few months are needed to erect the largest building, together with the surprisingly low cost, it must be evident that the time of steel-skeleton buildings, with all their flimsy lug and bracket connections, their insufficiently protected columns and their high cost, is past, and that they must give way to a far superior type which will be the construction of the twentieth century.

The photographs show the great range of work done by M. Hennebique, including factories of all kinds, as flour and spinning mills, ice-factories and foundries with heavy travelling-cranes, the runways being also of concrete-steel, smoke-stacks, storage-houses and power-blocks, apartment and office buildings of fifteen stories in height, department-stores, theatres, museums, banks and fireproof vaults, domes and churches, markets, railroad-stations and small switch-houses, free-supporting staircases, floors of any practical span (those in the Grand Palace of Fine-Arts in Paris having a span of 33 feet and a cantilever of 11 feet), exhibition-buildings, coal-bins, water-towers, grain-elevators, power and irrigation canals, tunnels, retaining-walls, wharves and piers, and (last, but not least) bridges.

Armored-concrete bridges are indestructible, requiring no supervision or repairs. If of moderate span, they are cheaper than steel bridges and have always a fine architectural appearance.

[1] A paper by Mr. Leopold Mensch, C. E., read at a meeting of the Civil Engineers' Club of Cleveland, and printed in the *Journal* of the Association of Engineering Societies. Continued from No. 1405, page 70.

Through the columns of *Engineering News* of this year, we have learned the disastrous results of adopting the so-called "leg bridges" for country roads. They consist of steel pipes, forming the abutments, and plate or lattice girders carrying the floors, the two being connected by brace-angles. They failed by scores. A few concrete-steel piles and a 4-inch curtain-wall as abutments, a few armored-concrete piles mid-span and a concrete-steel floor, monolithically connected with these piles, will make a bridge as cheap as a "leg bridge," but far better and indestructible.

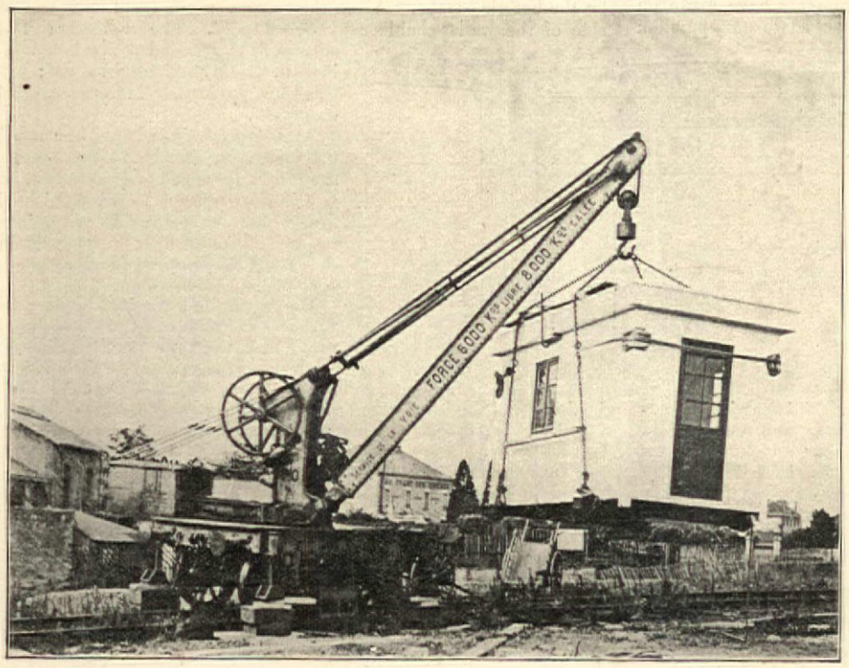

Fig. 20. Transportable Guard-house for Orleans Railroad, France.

Figure 17 shows a typical cross-section of a ferro-concrete bridge of moderate span. The floor of the roadway and the cantilever sidewalks form the compression-flange, while the rods in the bottom of the girders proper form the tensile-flange of a huge girder, and, for the same reason as in floors, this type of bridge is much stiffer than are plate-girder bridges. The cross-girders, roadway and sidewalks are all built of ferro concrete.

Figure 18 shows a longitudinal section of the bridge of the Quai Debilly, in Paris. This is composed of twelve armored-concrete arches of 46 feet span, placed about 8 feet apart. The rise is 2 feet, or $\frac{1}{23}$ of the span. The floor for the roadway and sidewalks varies in thickness, and is supported by armored-concrete cross-girders and is about 100 feet wide. The abutments and foundations, also built of armored concrete, are of special design.

Figure 23 shows a section through the retaining-walls. A curtain-wall, 6 inches thick, is connected by means of deep ribs with a platform at mid-height. This platform supports a load of earth 10 feet deep, which in the simplest manner prevents overturning of the walls. The bridge was calculated for a uniform load of 123 pounds per square foot, and for a train of 10-ton wagons. It was tested on February 6, 1900, by a uniform load of 123 pounds per square foot, 248½ tons in all, and gave a maximum deflection of only ¼ inch, or $\frac{1}{2154}$ of the span.

A second example is the bridge of Chatellerault, over the river Vienne, in France. This is the greatest work of art that has been constructed on the Hennebique system. The total length of the bridge is 443 feet, and consists of three spans, the end spans of 135 feet with a rise of 13 feet, and a central span of 164 feet and a rise of 15 feet 8 inches. Four arched ribs in armored concrete, 20 inches deep, support the floor of 25 feet width by means of 8″ x 8″ posts. The sidewalks partly overhang. The total thickness of the bridge at the crown is only 28 inches.

It will be noticed that this bridge is designed on the same lines as would be expected in steel-arch bridges, such as the Washington Bridge in New York; and the lightness of this structure explains its surprisingly low cost of hardly $35,000.

The foundations of the bridge were easily laid, the calcareous rock being found at 5 feet below low-water mark. The piers and abutments consist of heavy ribs, corresponding to the four arched ribs and connected by curtain-walls 5 inches thick, to give them their external shape and stiffness. They were filled with low-grade concrete of hydraulic lime.

The bridge was calculated for the passage of two 16-ton wagons, and for a uniform load of 100 pounds per square foot. The concreting of the bridge was done in less than three months, and five weeks later the centring was removed. The tests with stationary loads were made in the following manner: each span was loaded over its total length, then on each half, then on its central part, with moist sand at the rate of 165 pounds per square foot on the roadway and 123 pounds on the sidewalks.

The official report of the test says: —

The maxima of the deflections were ¼ inch for the arch of the left shore, $\frac{7}{32}$ inch for the arch of the right shore, and $\frac{13}{32}$ inch for the central arch, that is, $\frac{1}{1800}$ and $\frac{1}{5000}$ of the spans respectively. The specifications allowed deflections of $\frac{9}{16}$ inch for the 135-foot span and of 2 inches for the 164-foot span. After removing the loads no permanent deflection could be detected.

The moving-test load was composed of: —

First. — One 16 ton steam roller.

Second. — Two two-axle wagons weighing 16 tons in all.

Third. — Six single-axle wagons weighing 8 tons in all; making a total of 40 tons moving simultaneously over the bridge, the sidewalk of which had to carry also 80 pounds per square foot. The maximum deflection reached was less than $\frac{1}{6000}$ of the span.

Furthermore, 250 infantrymen were made to cross the bridge, first in ordinary marching order, then in double-quick time. Also, strips of wood were strewn over the roadway in order to produce shocks when the steam roller passed over them.

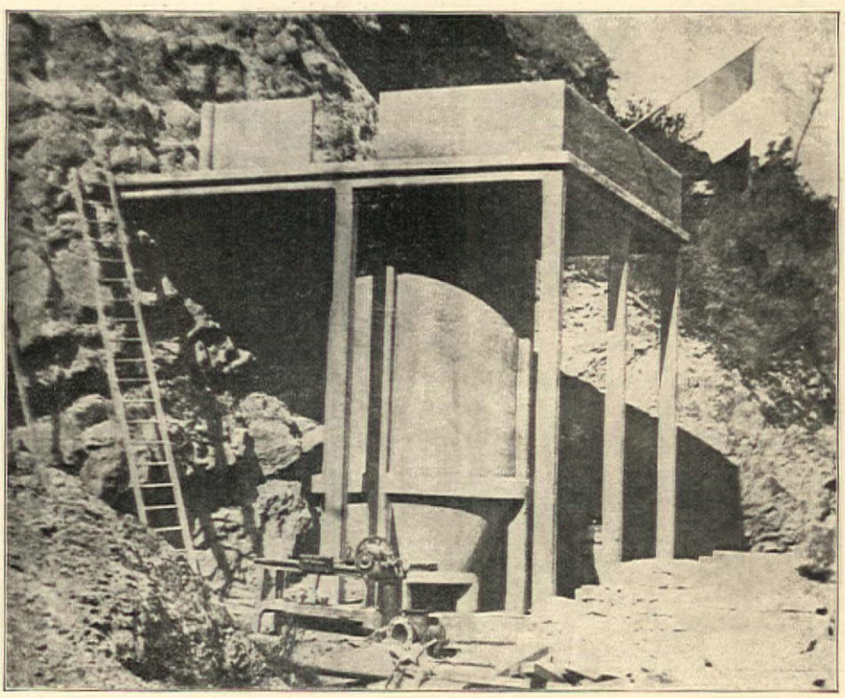

Fig. 21. Limekiln, Luzech, France.

But the most remarkable feature shown by these tests was that the three arches were in fact continuous, so that the load which caused a depression in one arch produced at the same time a rise of the other arches, an evident proof that ferro-concrete structures are monoliths.

You will be surprised at the numerous applications of the

Hennebique system. The explanation is simple. The inventor has been able to interest in his system a great many engineers, architects, practical and scientific men, who have imparted to him their ideas and have become his collaborators.

Europe is to-day in the lead of concrete-steel structures. Let us hope that the enterprising American spirit will, as energetically as formerly with regard to steel, take up and lead in this, which is undoubtedly the greatest industry which we have to expect in the twentieth century.

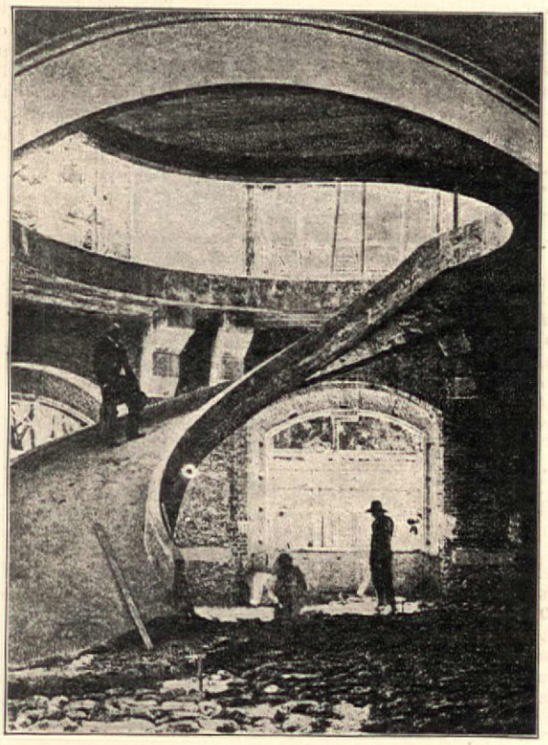

Fig. 22. Staircase in the Palace of Fine-Arts, Paris Exposition of 1900.

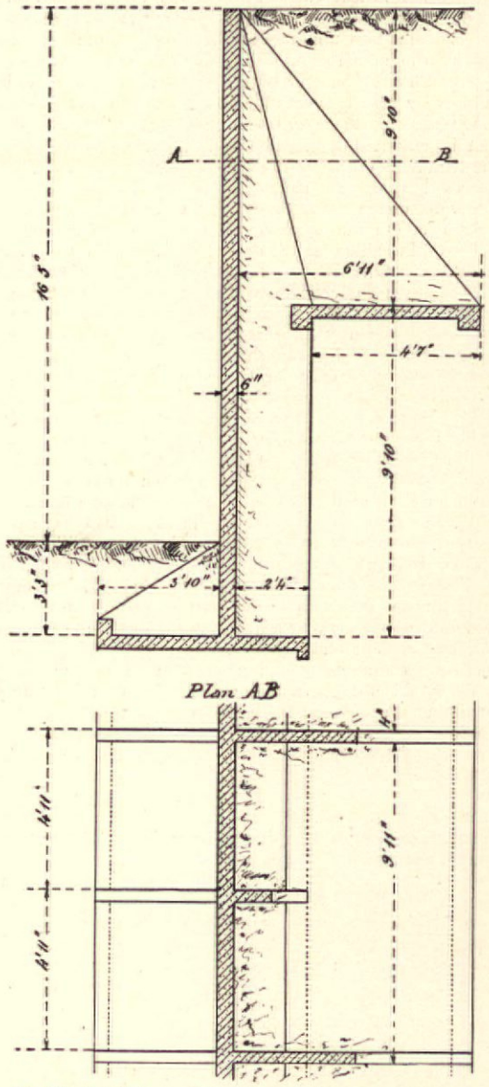

Fig. 23. Retaining-wall of the Quai Debilly, Paris, France.

PARIS

DIPLOMAED AND NON-DIPLOMAED ARCHITECTS. — THE DRY-ROT FUNGUS AND THE RESPONSIBILITY OF ARCHITECTS.

THE profession of the architect is not, in France, an easy one to practise, yet, demanding, as it does, a multifarious practical knowledge and a certain amount of artistic education, it is nevertheless open to every one, and each man can, between one day and the next, assume the title of "architect" without having had to furnish any proof of his capacity. Being obliged to fill the delicate office of proxy for another, an architect is not compelled to give any bond to the man whose interests he undertakes to defend. Physicians cannot practise medicine until they have won the title of "doctor," advocates cannot plead in court until after they have obtained from the Faculty of Law the title of "licentiate," and have passed several examinations; and from engineers are exacted diplomas declaring their successful passage through the great schools of the State. But from the architect nothing is demanded.

The École des Beaux-Arts does, indeed, confer a diploma declaring that an architect has there completed certain studies in a satisfactory manner, but this diploma is a very special affair, and, consequently, elective, and many capable architects cannot have a diploma although they have passed through

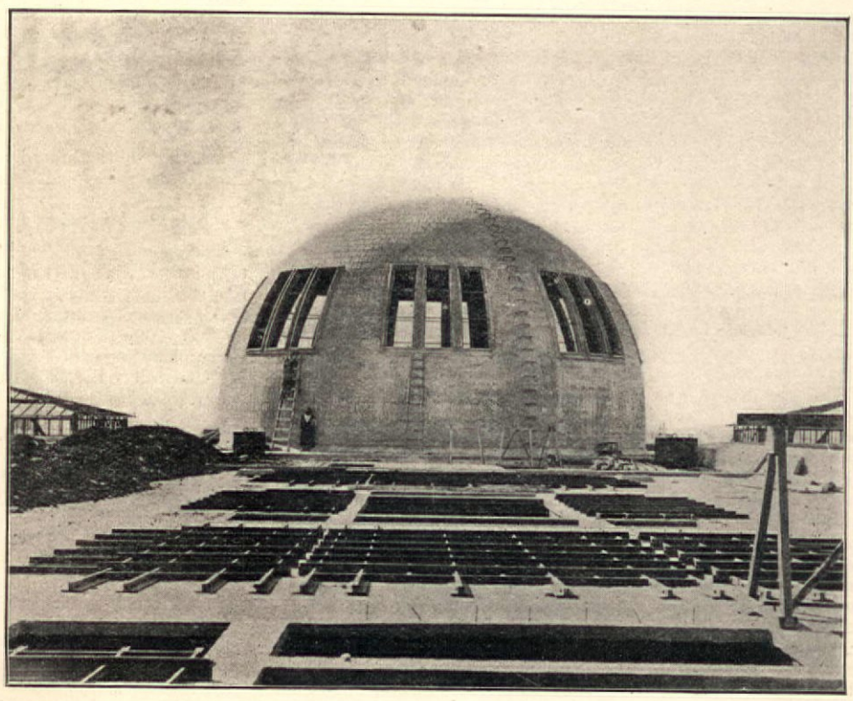

Fig. 24. Dome of the Museum of Egyptian Antiquities, Cairo, Egypt.

the École des Beaux-Arts. The non-diploma-owning architects, especially in the Provinces, complain of the competition they are forced into with architects who have gained their diplomas; while the latter, on their side, express their regret that the obligation of winning a diploma does not defend them against the ignorant and the charlatans who encumber and dishonor the profession.

For a long time this matter of the diploma has been under discussion, and every year it makes its appearance in the programmes of our Congresses, but there will be a great deal of trouble in bringing it to an issue. A diploma, in the first place, can only be pertinent to the technical and scientific side of our profession. Art cannot be described by any certificate, and a client, amateur of modern art, might well mistrust the worth of a diploma issued by our National School. On the other hand, a technical education can be had as well at Marseilles, at Toulouse, at Lyons, in the North, as well as at Paris. One cannot demand that all the architects in France should learn their trade at Paris; there should, therefore, be created in the Provinces regional schools, and this is an aspiration which has been frequently expressed, and which will shortly result in something. But if a diploma should be definitely adopted would it give a satisfactory remedy for the evils of which we at present complain?

At the late Congress, last June, M. Fernoux declared that it would not: a diploma could never confer upon those who have won it the sole right of conceiving plans and carrying them into execution; could never possibly prevent a contractor from building a house, or a client from purchasing this house after it had been built. Since, then, he had the right to purchase it, he must also have had the right to cause it to be built by any one that he chose. The selection of an architect depended upon that which the client wished him to perform. There were cases where a practical man was of more use to a client than an artist would be, and choice in most cases is usually made only after making inquiries, and gathering information as to the capacities of the man who must defend the client's interests. Even though all architects should be diplomaed, in one fashion or another, this would not prevent the client from making inquiries before entrusting an architect with his business; just as he makes inquiries before selecting a physician, an advocate, or an engineer. And this is why the eternal question of the diploma, so much discussed in France, arrived at no definite conclusion this year any more than in former years, and explains why the propositions advocated were not adopted.

Architects, therefore, will probably have for a long time yet to enter a competition which expands ceaselessly. Like all professions, that of the architect is to-day very much crowded in France; and, nevertheless, it is not among the most easy and most tranquil. The architect in France has to observe police-regulations, and very stringent street-front laws which constrain his free action, in sometimes an excessive degree; and, besides, for the last ten years he has had to bear a responsibility which may be terrible in its consequences, and against which all his knowledge and his experience cannot always preserve him. You will find the proof of this in the extremely interesting discussion at the last Congress, apropos of the dry-rot fungus, the "merulius lacrymans," with which the Congress of 1901 also concerned itself. This fungus causes considerable damage in wood, and because of the severity of the *code civil* in this respect, an architect may find himself in a position of responsibility for the damage it produces.

So far as concerns the "merulius lacrymans," is not this responsibility excessive, and can the danger of using the lumber be recognized at the moment when it is introduced into the building? Can the ravages of this growth be stopped? These are the questions which have been discussed in the remarkable report at the last Congress by M. Olive, Architect and Secretary of the Société Centrale. M. Olive, in the first place, described the ravages caused by the "merulius lacrymans" on which, in 1893, M. Crié, of the Faculté des Sciences de Rennes, laid the failure of many scaffoldings in several cities of France, and the falling of innumerable roofs and floors. The same condition of things exists abroad — in Austria, Russia, Germany, where able botanists are carrying on special studies in this subject. In 1898 a commission was appointed by the Association Internationale for the Testing of Materials, with a view to studying this very question of the dry-rot fungus. Thanks to the studies of this commission, there have been obtained certain facts, which, to some degree, give us a definite knowledge of this redoubtable enemy. From these investigations it appears that the rotting of the wood can be very rapid, and that it is often caused by mushrooms which attack the tree while it is still growing. The vegetable fibres of these mushroom growths are invisible to the naked eye, and can only be seen through the microscope by observers familiar with vegetable anatomy. Botanists, at least, might be able to recognize the presence of this fungus growth at the time of felling. But there is another kind of decay which cannot be discovered at the time of felling, and which reveals itself only after it has reduced the pieces of wood to powder — the principal agent in this decay is the "merulius lacrymans." Wood affected by it presents a yellowish-brown color, and is covered by light specks of clear white, which have the appearance of filaments of gray cotton-batting interwoven with one another. These form irregular white sheets, in the midst of which appear yellowish plaques in the form of little flakes, which finally become covered with bright orange-colored dust, formed by the innumerable spores or seed-vessels of the fungus. This fine dust is easily scattered, and can thus infect sound wood. Fortunately, all these seeds do not germinate and only a small portion meet with conditions favorable for their development. Among these favorable conditions humidity is of the chief importance. Certain remedies have been suggested for stopping the propagation of the evil: creosote, currents of dry air, dilute sulphuric-acid, sulphate of copper (one kilogramme to 10 litres of water).

"In any event, for us architects," M. Olive says, at the end of his essay, whence I have drawn the statements herein, "it is enough to state that botanists, men conversant with such matters that is, confess their inability to detect this plague early enough to take precautions against it, and that they have not yet found any efficacious means of stopping its growth, and causing it to disappear. This being so, why should the architect be held responsible for a destruction caused by the fungus? Yet, nevertheless, judgments have been given compelling both architect and contractor to indemnify the owner of the building for loss occasioned by the "merulius lacrymans." On the other hand, a recent decree of the Conseil d'Etat has settled the jurisprudence of the matter in a more reasonable sense. The floor of one of the halls in a certain school fell; the experts recognized that the catastrophe was brought about by the rotting of the wood caused by the fungus, whose existence had not been detected when the wood was being built in. The Conseil d'Etat dismissed as defenders both the architect and contractor alike; and this is the theory that M. Olive would like to have recognized everywhere, and there is no architect who will be found to oppose him. Supporting this conclusion, M. Lalanne, Vice-President of the Société Centrale, would like to see the same principle applied to the cases where wood is destroyed by the worms vulgarly called "*vrillettes*," whose inroads always begin in the builder's yard or in the house.

M. Moyaux recalls in this connection that having to tear down a small house, about thirty years old, he discovered that all the timber, flooring and beams were attacked by these "*vrillettes*," and that posts 18 to 20 centimetres square were reduced to the thickness of an umbrella. All this is not very reassuring; hence, the following expression of opinion has been unanimously adopted at the Congress of 1902: —

"In consideration of the fact that it is practically impossible to discover, in wood apparently sound at the time of being built-in to a structure, the presence of a deposit of eggs which will engender "*vrillettes*," or of spores which later must develop the filaments of the "merulius lacrymans"; and considering, further, that this deposit can be made at any moment, through an external agency, the Congress expresses the belief that the responsibility of the architect in such cases should not be involved."

And now let us hope that this aspiration may be taken into consideration by the tribunals, and that the courts may show themselves less harsh toward architects, whether or no they have won their diplomas, — the "*vrillettes*" and the "merulius lacrymans," unfortunately, not being influenced by diplomas.

AMERICAN INSTITUTE OF ARCHITECTS.

PROGRAMME of the Thirty-sixth Annual Convention, to be held in Washington, D. C., December 11, 12 and 13, 1902.

Order of Proceedings. — Wednesday, December 10.

Meeting of the Board of Directors at 10 A. M. in the Octagon, Eighteenth Street and New York Avenue, Washington, D. C.

Thursday, December 11.—*Morning Session.*

The members of the Institute will meet in the Assembly-rooms of the New Willard Hotel at 9.30 o'clock; will register their names; the President will appoint a Committee of Three on Credentials of Delegates, and at 10 o'clock there will be a short address of welcome by Col. John Biddle, U. S. A., Engineer Commissioner, District of Columbia, after which the President of the Institute, Mr. Charles F. McKim, will make brief remarks, when the Convention will be declared open for business.

Order of Business.

1. Report of the Board of Directors.
2. Report of the Treasurer and reference to the Auditing Committee.
3. Reports of Chapters, a synopsis of which will be read by the Secretary.
4. Reports of the Standing Committees: —
   - (*a*) House and Library Committee, Robert Stead, *Chairman.*
   - (*b*) Education and Publication Committee, H. L. Warren, *Chairman.*
   - (*c*) Foreign Correspondence Committee, Glenn Brown, *Chairman.*
   - (*d*) Contract and Lien Laws Committee, Alfred Stone, *Chairman.*
   - (*e*) Applied Arts and Science Committee, W. G. Preston, *Chairman.*

5. Reports of Special Committees: —
   (*a*) Legislative Committee on Government Architecture, George B. Post, *Chairman.*
   (*b*) Delegate to National Conference Electrical Code, and to meeting of National Fire Protection Association, Alfred Stone, *Delegate.*
   (*c*) Conference with Architectural League on Competition, Codes and Coöperation, R. Clipston Sturgis, *Chairman.*
   (*d*) Committee on Competitions, R. Clipston Sturgis, *Chairman.*
   (*e*) Improvement of Washington Committee, W. A. Boring, *Chairman.*
   (*f*) Fine-Arts Commission and Bureau of Architecture Committee, Robert S. Peabody, *Chairman.*
   (*g*) Municipal Improvement Committee, Frank Miles Day, *Chairman.*
   (*h*) World's Congress Committee, W. S. Eames, *Chairman.*
   (*i*) Metric System Committee, James Knox Taylor, *Chairman.*

Luncheon served in banquet-hall at 1 o'clock. Ladies in attendance with members are invited.

Afternoon Session, 2 o'clock.

1. Appointment by the President of two Committees on the Nomination of Officers and Place of Meeting for Thirty-seventh Convention.
2. Appointment of Special Committees to consider and report on recommendations contained in the Report of Board of Directors, of the Reports of Chapters, and of the Standing and Special Committees.
3. Papers on "The Improvement of Washington," illustrated by lantern-slides.
   (*a*) Daniel H. Burnham.
   (*b*) Frederic Law Olmsted, Jr.
   (*c*) Charles Moore.
4. Report of Credential Committee.

Evening Session.

The members will meet at the Library of Congress at 8.30 o'clock to view drawings and models submitted by the Park Commission, D. H. Burnham, C. F. McKim, Augustus St. Gaudens, and Frederic Law Olmsted, Jr. Explanation by member of the Commission.

Friday, December 12. — Morning Session.

1. Paper: "The Relations of the Architect and the Engineer" — Captain John Stephens Sewell, Engineer Corps, U. S. A.
2. Reports of Special Committees.
3. Unfinished business of the previous day.
4. Ballot open for the election of officers.

Luncheon served in the banqueting-room at 1 o'clock.

Afternoon Session, 2 o'clock. — Held in Assembly-hall of the New Willard.

The Development of Municipal Improvement will be the principal topic for consideration. Papers and discussions illustrated by lantern-slides.

   (*a*) W. B de las Casas. "The Organization for Municipal Improvements."
   (*b*) Albert Kelsey. "The Modern City."
   (*c*) Owen Fleming. "Improvements in London, Eng."
   (*d*) E. L. Masqueray. "Water Effects in Landscape as applied in St. Louis Exposition."

Saturday, December 13. — Morning Session.

1. Reports of Committees appointed at the opening session and their consideration.
2. Unfinished business.
3. Miscellaneous business.
4. Ballot closed and announcement of officers elected and the place of meeting for the next Convention.

Afternoon Session, 2 o'clock.

1. Unfinished business.

Exhibitions, December 10 to 14.

1. Drawings and photographs illustrating the proposed improvements of Washington by the Park Commission; on view in the Congressional Library.
2. Exhibition of the competitive drawings for the new Municipal Building, Washington, D. C., in the Octagon, corner Eighteenth Street and New York Avenue, N. W.

Delegates will be distinguished by a red ribbon, and will occupy seats from the front row as far back as is necessary for their accommodation.

Members of the Institute who are not delegates are entitled to enter all discussions, to offer resolutions and motions, and to vote on a proposition that it is "the sense of the meeting."

Prompt and full attendance on the successive sessions at the hours indicated is requested, otherwise the business of the Convention cannot be fully accomplished.

Committee of Arrangements. — Glenn Brown, Robert Stead, Wm. A. Boring, Edgar V. Seeler.

Per order of the Committee,

GLENN BROWN, *Secretary, A. I. A.*

NOTES AND CLIPPINGS

ECONOMIES OF THE SO-CALLED STEEL TRUST. — The December *Century* contains a paper on the "Steel Trust," by Henry Loomis Nelson, which embodies statements of an authoritative character concerning that organization, including the paragraphs which follow, setting forth the claims of the Corporation as to the economies which it has brought about. Mr. Nelson says: "Among the leading causes of low prices is low cost of production, and this is obtained by the economies which the combination has rendered possible. The fact that economies are possible is clear. In the first place, not one of the subsidiary companies possessing ore owned every kind of ore which it needed in its work. The Illinois Steel Company and the Carnegie Company, for example, were obliged to purchase ores for mixing with their own. The United States Steel Corporation buys no ore. In the second place, there is an enormous saving in the item of transportation. The great fleet of the Corporation sails about the lakes, stopping at the mines for loading, departing at once on receiving the cargo, notified then or on its passage at what wharf and for what furnace the ore is to be delivered. There is no loss of time, as there used to be when the boats, belonging to different and competing companies, were obliged to wait their turn at the loading-wharf, while there was further delay at the destination, either by reason of failure of land transportation, or because the furnace was not ready for the ore. Now the ore is carried directly to the furnace at which it is needed, and the former waste is saved. Another economy

is the consequence of the possession by the company of virtually a complete equipment for the iron and steel business. Orders that once were taken by one mill can be distributed among the several mills which formerly were competitors. This not only secures promptness in executing the orders, but where once the mill machinery was changed as it passed from the making of one size to the making of another of pipes or rods or other forms, there is now no such loss of time, for sizes, like forms, can be distributed to the proper number of mills. There is also economy in administration; there is no waste of effort and of men in competition for orders; and the product once sold through scores of agents is now disposed of by a few. But the chief advantage of this combination is expected to be gained through economy of production, not in the number of salaries saved, and not merely in the utilization of existing methods and means of manufacture. No one can question the fact that in competition there is great waste; the question is whether the consumer gains or loses by the struggle which results in this waste. It is true, however, that those who now are interested in the United States Steel Corporation have been saved enormous expenditures of material, and have also been saved losses which might have brought serious disaster to all directly or indirectly dependent on the iron and steel business. There is no reason now why the group of men who carry on from 70 to 75 per cent of this business should build a single mill more than the demands of the business warrant, and if we recall the war which was in progress at the time of the formation of this Corporation, the importance of this will be manifest. The manner in which the Corporation is administered, however, is of the first importance. The question here is whether the men who have combined are taking every advantage of the opportunities for effecting the purpose which they profess to have in mind."

New Building-laws for Paris. — John K. Gowdy, United States Consul-General at Paris, in a dispatch to the State Department, reports: "New regulations concerning the erection of buildings in Paris have just been issued by the municipal surveyors, as the decrees hitherto in force (though they dated no farther back than 1882 or 1884) did not satisfy modern requirements in the matters of hygiene, comfort and luxury. The height of buildings is thus fixed: If the road is less than 12 metres (39 feet) wide, the height of the building must not exceed the width of the street by more than 6 metres (19½ feet). On a roadway 12 metres wide, the house may therefore be 18 metres (59 feet) high, and for every additional meter in the breadth of the road, a quarter of a metre (about 10 inches) may be added to the height of the house until the limit of 20 metres (nearly 66 feet) to the eaves is reached; but no building may exceed that. In all dwellings, whether situated on a public or private road or in a courtyard, the height of the ceiling of the ground-floor apartment, and also that of the entresol, shall not be less than 9 feet 2 inches. Projections — bases of columns, balconies, corbels, bow-windows, etc. — are subject to certain general regulations, which may be modified in special cases. Thus, if a roadway is 52 feet or more wide, the regulation width of the balconies may be increased by one-fourth. A new and useful clause in the decree provides that any shutter, blind or sunshade placed not more than 10 feet above the pavement must either be within the body of the wall or must not open outward. There are also minute regulations concerning verandas, awnings, sun-blinds, outside lamps, cornices and signs." — *N. Y. Times.*

Humors of the Custom-house Officers. — There are many artistic jests, not intentional, but all the more amusing, in the decisions of the Treasury Department under the tariff-law, published every Thursday under the title of Treasury Decisions. When the United States General Appraisers at New York are called upon, by some protest against a decision of the Collector of Customs, to ascertain and declare, for instance, whether "a screen made of wood, silk and cotton, the panels of which are ornamented with landscapes and figures painted in oil" is to be considered as "a manufacture of cotton, wood and silk, cotton chief value," or as "a painting in oil or water-colors," it is evident that there is an opportunity for ponderous legal definitions which are not without their comical side. It is certainly amusing, though the importer may not see it, to have a "screen made of wood, silk and cotton, the panels of which are ornamented with landscapes and figures painted in oil," returned for duty as "a manufacture of cotton, wood and silk, cotton chief value." As the invoice value of the screen is $1,200, it is quite surprising to note how valuable the cotton (which, incidentally, has a painting upon it), must be. The force of the point is enhanced by the fact that if the object is "a manufacture of cotton" it must pay a duty of 45 per cent *ad valorem*, whereas if it is only "a painting in oil or water-color" it need pay only 20 per cent *ad valorem*. The decision of Mr. Somerville, General Appraiser, is that the screen is a "painting in oil or water-colors." It is, therefore, dutiable at 20 per cent, and the decision of the Collector is reversed. We approve of the decision, but the legal argument by which it is arrived at excites wonder, awe and amusement. Screens, it seems, are not enumerated *eo nomine* in the present Tariff Act, except in Paragraph 382, which refers only to those which are *ejusdem generis* with "mats, rugs for floors, screens, covers, hassocks, bed-sides, art-squares," which are made wholly or in part of wool, and which are made subject to the same rate of duty as is imposed on carpets or carpeting of like character. The General Appraiser is therefore bound to follow certain rulings of the Circuit Court for the Southern District of New York in parallel cases, which he does, without much enthusiasm, though the equitable and sensible nature of these rulings is self-evident. For example, a certain lot of "fans composed of silk and bone," decorated with paintings in water-colors, were held to be dutiable, not as manufactures of silk, but as paintings. This ruling was made upon the theory that at least two-thirds of the value of the fans was imparted to them by reason of the painting, and not by reason of the material upon which the painting was made. So in the case of a lot of paintings in oil upon panels of papier-maché, designed to go in the frame of a false door, which were held to be dutiable as paintings, and not as manufactures of wood. So also in the case of certain Japanese wall-decorations made of paper, paper and cotton, or of narrow strips of bamboo joined together with cotton cord, having upon them representations of human figures, birds, etc., in water-colors, which were held to be dutiable as paintings, and not according to the component material. The last ruling of the Circuit Court upon an analogous subject is found in White *vs.* United States (113 Fed. Rep., 855). It was there decided that ceilings painted on wood, taken from a palace in Italy, should be classified as paintings, and not as manufactures of wood. "The value of the wood," remarked the sapient judge, "as compared with the paintings, is infinitesimal." It is thus to be observed that while the mental processes through which these conclusions are arrived at seem somewhat more complicated and ponderous than necessary, the decisions are obviously sound, reasonable and just. — *Boston Transcript.*

Thawing Water-pipes by Electricity. — A regular occupation for the electrical force at Sault Ste. Marie is the thawing of frozen water-pipes. The work has been carried on by William Gorby for the last six years, and his work was begun on a hint given by a college professor. He tried it at the first opportunity, and found that the pipe was in service in a few minutes. Since that time he has thawed out all sorts and sizes of water-pipes, at a great saving of money to the owners. The largest thawed out was a 4-inch cast-iron pipe which was frozen more or less for 200 feet. It took half an hour to get the water running through it. A 250-kilowatt transformer is mounted on a sleigh, although nearly all the pipes could be thawed out by a 500-light transformer. The primary wires (2,200 volts) are bared, and the current led through a water rheostat to the transformer. The secondary is connected to the frozen pipe at two places, and the current switched on. In the ordinary house-service pipes, the water begins to flow very quickly, frequently within a minute. Although it may seem dangerous handling the primary current in this way, it is declared that no accidents have happened, and the apparatus has never failed in getting a frozen pipe working. — *N. Y. Evening Post.*

Artificial Island to be built in New York Harbor. — A new island is to be built in New York Harbor, between Ellis Island and Bedlow's Island, for the erection of a hospital for the care of immigrants suffering from contagious disease. This is one of the improvements recommended by Supervising Architect Taylor, who has been at Ellis Island making an investigation of the needs for additional accommodations for the United States Immigrant Station. He has recommended that the main buildings be enlarged at a cost of approximately $300,000; that the existing hospital be enlarged at a cost of about $100,000, and that an island of several acres be built up and a hospital erected on it at a cost of about $250,000. His recommendations have been approved by Assistant Secretary Taylor, and he has been directed to prepare plans and estimates for the work. When this has been done Congress will be asked to make the necessary appropriations. The improvements are made necessary by the rapid increase in the number of immigrants arriving at New York. — *N. Y. Tribune.*

The Manuscript of Ruskin's "Seven Lamps of Architecture." — J. Pierpont Morgan, according to a dispatch from London, has made a most interesting addition to his collection of literary treasures by purchasing for $25,000 the manuscript of John Ruskin's "*The Seven Lamps of Architecture.*" "*The Seven Lamps of Architecture*" was written by Ruskin in the autumn of 1848, soon after his marriage to Miss Euphemia Chalmers Gray, who afterward became the wife of Sir John Millais, P. R. A. Ruskin's brief married life was marked by a period of great literary activity, and a few months after Miss Gray became his wife he felt free to pursue the completion of a task which he had some time before set himself — the writing of a book in which some of the principles he had sought in "*Modern Painters*" to enforce in the case of painting should be applied to architecture. The Seven Lamps were those of sacrifice, truth, power, beauty, life, memory and obedience. It was published on May 10, 1849, and has been the most widely circulated of all Ruskin's larger works. It was the first of them to be illustrated. — *N. Y. Times.*

Brick Foundations. — It was only a few years ago that any one who walked along the street where a good building was being put up saw nothing but stone foundations. This condition has changed. Builders used to think that a man who had a brick house with a stone foundation and slate roof had reached the acme of excellence. As it is now, stone foundations are rarely known. The old stonemason is now practically out of a job. And for what reason, may we ask? Merely because of the excellence of brick. A better foundation, one more solid, one cheaper, one more satisfactory, one straighter and altogether better can be built from brick than from stone. It is one of the changes that have been made within recent years because of the high character of brick. Stone may be used for facing for alleged artistic reasons, but it is backed up by brick, and below the facings we find brick. This was slow in coming, but at this time the best buildings of all classes are provided with foundations not of stone, but of brick, and for the reason that brick is the better material. — *The Clay Worker.*

The Ashes of Columbus now in Seville Cathedral. — The ceremony of depositing the ashes of Christopher Columbus in a special mausoleum was carried out in the Cathedral last month with befitting solemnity. The coffin was borne on the shoulders of a party of naval seamen and behind it walked in procession the Archbishop of Seville, the Cathedral Chapter, the Minister of Marine and a number of other dignitaries. — *Boston Herald.*

NOTES AND CLIPPINGS. 87

THE case of the painter in New York State who was expelled from the painters' union because he had belonged to the State militia has excited much interest throughout the country. It seems that the painter, William Potter, after his expulsion from the union, wrote to every master-painter in the town in which he lived, asking for employment, and received letters from all, refusing it, on the ground that they could not employ non-union men, some of them expressing their regret that they were unable to do so. In consequence of this, Potter applied to the courts, alleging that neither the union nor any of its members had any property out of which damages could be collected, and praying that an order might be issued, commanding the union to reinstate him. It is pleasant to learn that an order to this effect was promptly made, and, unless the union restores him to his standing, all its members are liable to punishment for contempt of court.

THERE is no need of dwelling on the un-American tyranny and degradation of a system by which a gang of confessed paupers can rule absolutely an honorable profession in a community of considerable importance, as all this has long been familiar to everybody; but the point in which this case differs from any other is that the courts have, apparently for the first time, issued to a union a definite command, and thereby put unionism generally in a position of great perplexity. It is obvious that if the members of unions can, by command of courts, be compelled, not only to desist from oppression, but to do acts of justice, they become like ordinary citizens, and the absolute and irresponsible power, practically of life and death, with which they have kept their victims in terror, disappears. It is needless to say that if a man expelled from a union on account of belonging to the militia can be reinstated by the public force which carries out the decrees of courts, the men who have been deprived of their living in the same way on account of being too old, or not having been born in Belgium, or being too ambitious and industrious, or not drinking enough beer at a certain saloon, or having incurred in some way the ill-will of an influential "champion of labor," will soon be besieging the courts for justice, and the tyrants who by starvation and murder have established their authority over the best class of citizens that we have in this country will at last find a curb put upon their energies. The "labor champions" understand all this perfectly, and it is certain that every possible effort will be made to evade the direct conflict of authority between the courts and the unions which the Potter case has raised, either by getting Potter quietly away to some other place, and finding him satisfactory employment, on condition of his letting the case drop; or by raising some different issue, which will save the union the humiliation of submission to the constituted authority in the vital matter of the admission of a member to their ranks. What the result will be in the present instance no one can tell, but the issue, having been once raised, is sure to make its appearance again.

WHAT it would be a great advantage, in the end, for the unions to be subjected, like other associations of citizens, to the control of the courts is unquestionable. Nothing has done more harm to the union workingmen of this country than the feeling of great and irresponsible power over other people, which could be exercised arbitrarily or maliciously, and practically without restraint, so long as the members of the unions were careful not to save up money for their families, which might be held liable for damages. Although the general sense of honesty and decency, which is very strong among those who work hard, has kept them at ordinary times within reasonable bounds, the excitement of strikes has led even the better class of union men to unjustifiable measures, and the impunity which these have found, joined with the steadily degrading influence of the premium placed by union methods on improvidence, have cultivated in the union members a contempt for law, and for the rights of other people, and an indifference to the duties and responsibilities of citizenship, which are particularly dangerous in a democracy like ours, which is largely ruled, and has hitherto been well ruled, by workingmen. The compulsory incorporation of unions, by restoring the liability of corporate property for the debts or misdemeanors of the union, as well as by freeing the individual property of the members from such liability, would do very much to encourage workingmen again to make provision for old age or misfortune, as well as to feel themselves again sharing all the duties and responsibilities of citizens; and the recognition of the authority of the courts over them would complete the assimilation of workingmen to the rest of the community which has made our country what it is. That those who have found profit for themselves in separating workingmen into a class apart should dread their incorporation again into the great body of American citizenship is to be expected; but the tendency toward such a change in the position of working people is clear, and there are many indications that the abolition of the barriers between the so-called "classes" which theorists and demogogues have for so many years been trying to establish will be followed by a mutual respect and regard which has never been known before, even in this country. There has never been a time when so little of the pride of family, one of the most hard-hearted varieties of that sin, existed here, it having been all but swept away by the flood of new wealth which has overwhelmed it; and, although there is such a thing as the pride of wealth, it rests on so insecure a basis as not to be very dangerous; while, as a matter of fact, nearly all our very rich men have themselves been workingmen, and are not only proud of the fact, but use their knowledge of the needs of workingmen, and their sympathy with them, in a way which signifies more for the future of the Republic than most people imagine. When we reflect that it is not much more than a hundred years since Marie Antoinette, if we may believe the legend, when she heard that multitudes of her subjects were without bread, wondered why they did not eat cake, and then observe Mr. Andrew Carnegie devoting enormous sums to providing, with anxious and wise care, those advantages for the poor boys and girls of the future of which he felt the need when he was himself a poor boy; or Mr. Charles M. Schwab, brightening the existence of the thousands of people who work under his direction by his unfailing interest and kindness; or the Bishop of New York, to whose impartial sympathy employers and employed resort with equal confidence; or the Tenement House Commission, through which the very poor have been brought nearer to their more fortunate fellows than ever before; or the thousand and one ways in which poor people are made to feel the personal interest and consideration of richer ones, the devices of designing politicians and demagogues to set the poor against the rich, and to keep them poor that they may do so more effectually, seem horrible anachronisms, which must, sooner or later, be swept away, and which every American who loves his country and his countrymen should help to sweep away as quickly and effectually as possible.

THE recent successful tests in New York of the practicability of sending a stream of water from a fire-engine into the upper stories of the new "Flatiron Building," which is about three hundred feet high, have revived the public interest

Entered at the Post-Office at Boston as second-class matter

in the stand-pipe system, which alone makes such a feat possible. It is not long since some distinguished fire-engineer announced that everything above the twelfth or fifteenth story in a modern office-building was beyond the reach of any appliances at the command of fire-departments. It is evident that ordinary hose would not resist the pressure necessary to lift a stream of water to a height of three hundred feet; but there is no difficulty in fitting a building with permanent wrought-iron pipes, tested at a thousand pounds' pressure to the square inch, and so arranged that water can be pumped by fire-engines directly into them, and so conducted to any height. Years ago, when seven stories was the usual limit of height in mercantile buildings, it was a common practice to place on the street front of such buildings one or more vertical wrought-iron pipes, with a single or double coupling near the sidewalk, for making connection with a steam fire-engine, and an outlet in every story above, to which a hose could be attached in case of need. All the connections were closed with brass caps, attached to a chain, so that they could not be lost, but easily removable in time of fire. The same system has now been revived for the protection of high buildings, and might, with advantage, be required in all structures used for storage, manufacturing, mercantile or office purposes. For a lofty building the lower coupling should always be double, so that the power of two engines can be united to force water through the pipe; and it is now common to place the pipe either outside the building, or, more usually, just inside the wall, where it is safer from freezing, but near a line of windows, so that firemen can reach it from the outside, with ladders. In the case of a three-hundred foot office-building, outside ladders, unless in the form of a permanent fire-escape, would be out of the question, and the position of the stand-pipe for fire use is then determined by accessibility. In either case a good stand-pipe, as the tests at the "Flatiron Building" show, is an invaluable security. Even on the roof of the structure a pressure-gauge showed forty-seven pounds' pressure in the pipe, so that the water could easily have been forced a hundred feet higher still.

A VERY interesting paper was read before the London Agricultural Association a few weeks ago, by Mr. F. C. Eden, on "Roof Coverings," and the discussion which followed the reading brought out with peculiar emphasis the "eternal conflict" between the useful and the beautiful which gives the profession so many anxieties. As Mr. Eden began by quoting Goethe's saying, "Take care of the beautiful, for the useful can take care of itself," experienced architects can imagine what he thought of roof-coverings. His opinion that no roof is either more useful or more beautiful than one of good, hand-made, hard-burnt shingle tiles, not less than half an inch thick, will be shared by most American architects, and many of them will also agree that such tiles should not be selected for uniform color, and that a little warping in the burning is rather an advantage than otherwise; but those who have listened meekly to a client's animadversions on their attempts at picturesqueness are likely to hesitate before adopting, at least as a rule of practice, his opinion that the best ridge for a tile roof is made with plain half-round tiles, with a thick fillet of white mortar over each joint, and a bottle stuck in the end, as a finish over the gable.

SOME of Mr. Eden's other ideas of roof-finish would hardly appeal to the average client. Speaking of lead roofing, he mentions certain old English churches covered with this material, which have no gutter, but in which "the lead hangs easily over the eaves like a flounce, which gives a curiously forlorn look, not without charm." We imagine that an architect who accompanied his church building-committee on a visit of inspection of the "forlorn" effects which he had contrived for their benefit would never forget the occasion. In regard to projecting rafter-ends, also, he would be a bold architect who would venture to follow Mr. Eden's advice, and "space them unequally, and vary their sizes," however convinced he might be personally of the advantages of this arrangement. Within certain bounds, however, these suggestions are valuable. We once had a very considerate and satisfactory client whose instructions were confined mainly to one requirement — that everything about his house should be "square, true, plumb and level"; and the young architect who thirsts for an opportunity to astonish the world by the picturesqueness of his work will do well to ascertain beforehand his client's views on the subject; but having made sure of this point, some of Mr. Eden's observations might be applied with profit. In a tile roof, for example, he advises spacing the rafters far apart, so that the laths, when loaded with the tiles, will sag between them; and although this gives a suggestion of an old horse's ribs which is not quite pleasant, a certain safe sagging unquestionably adds much to the beauty of a roof, throwing the distressing parallel edges of tiles, slates or shingles into varying curves. In repairing the roof of the fifteenth-century house known as Ockwells Manor, Mr. Eden says that the purlins were found to be set at such a level that the rafters did not touch them by about an inch until loaded with the tiles, the effect being to throw the completed roof into gentle undulations, the prominent portions being over the main trusses. This effect must have been intended, and it illustrates curiously the passion for the picturesque which characterized the Middle Ages, and which has been so ably traced, in another field, by Professor Goodyear.

THE remarks made by the audience upon Mr. Eden's paper were about what might have been expected. One architect happened to have a reversionary interest in some real estate in Kent, "where," as he said, "could be found the features dealt with by Mr. Eden," such as oak timbers, hand-made tiles, and so on. The cottages on the property were exceedingly picturesque, and were often sketched or painted by artists, but they had one defect — from the landlord's point of view — that they were uninhabitable. Another hearer, while he agreed with Mr. Eden that rainwater gutters were not always desirable, and that a choked gutter or conductor would often do more harm in a few minutes than dripping eaves would do in as many years, observed that local building regulations always required rainwater gutters, whether they were picturesque or not; and a third "disagreed with almost all Mr. Eden's conclusions," for the very sensible reason that architects had to satisfy their clients in their houses, rather than themselves, and that clients were not likely to appreciate an inordinate picturesqueness, however gratifying it might be to the young artists who did not have to live in the houses. On the whole, however, the members of the audience agreed, as artists, with Mr. Eden, the doubt in their minds being whether architects were justified in imposing their own notions of picturesqueness on their employers.

STUDENTS of art do not know so much as they ought about the prizes open to them in this country. A few days ago the noble Lazarus Scholarship for mural painting, which gives to the winner three years' residence in Europe, with the ample income, for a student, of a thousand dollars a year, was awarded to the author of the best out of only seven competing designs. If artists realized that this great prize is only second in value to the Prize of Rome in the French School of Fine-Arts, and that, in these days of increasing demand for good mural decoration, the winner of such a prize has his whole future practically secure, the competitors should be counted by hundreds, and the competition itself should be one of the great events in the artistic world. Instead of that, in 1896, when the scholarship, which is triennial, was first awarded, there were only three competitors; in 1899 there were six; and this year one more has joined the lists. Although the three winners of the prize, Mr. Breck, in 1896, Mr. Schwartz, in 1899, and Mr. Rylands, this year, have all been pupils of the New York Arts Students' League, the scholarship is not restricted to New Yorkers. On the contrary, the competition is open to all unmarried male citizens of the United States who can pass a satisfactory examination in the history of architecture, free-hand drawing, and elementary French and Italian, and the sketches submitted are judged by the most accomplished experts in the country. American artists are accused, perhaps with some reason, of being too conceited to venture their work in competition with that of others. If there is any truth in this notion, the sooner they change their minds, the better it will be for them. Nothing does so much to clear out of an artist's head the fog raised by the flattery of his friends and the newspaper reporters as to try his strength in competition before a good jury. If he wins, he gains a better idea of his own capacities, as well as of his limitations, than he could get in any other way; and if he loses, he has the inestimable advantage of finding out where his weak points are, and in what ways his competitors surpass him, to say nothing of the increase of power which every man gains by doing the very best of which he is capable, and cannot gain otherwise.

BRONZE DOORS IN ITALY.

UPON every side artistic Italy is worthy of remark and attention; and if from the solemn "monuments" we descend to the complementary and decorative parts of these same monuments, in every one, or almost every one, we shall find objects worthy of study. To-day, I mean to discuss the matter of door-valves in wood and bronze; and even if I limit myself to the chief types, we shall find many models, an acquaintance with which will not be useless. I beg the reader to be assured that the information which I give is not improvised, but is authoritative and exact, particulars in which the writers of to-day are not over-careful.

For the sake of brevity I will not begin with the Greek and Roman epoch, but limit myself to the Paleo-Christian epoch. I call your attention, therefore, to the wooden door-valves, the most ancient of the Christian epoch. These are the doors in the basilica of Sta. Sabina at Rome, the objects of a wide and serious consideration by many writers of many countries. M. Kondakoff, the celebrated historian of Byzantine art, since June, 1877, has concerned himself with these doors, and aims at showing the high value of the opinion expressed by De Rossi, the prince of Christian archæologists, and of Cavalcaselle and Crowe, as well as of Doppert, to the effect that these doors date back to the sixth century, and not to the twelfth or thirteenth century, as has been supposed. Our author proves the earnestness of his opinion by a comparison with similar monuments, especially with the sarcophagi and ivory diptychs of the fourth, fifth and sixth centuries. Lately, a writer of high standing, M. Grisar, published on the same subject a very elaborate essay, which reached almost the same conclusion. This author, who also attempted to fix the exact date of the doors of Sta. Sabina, satisfied himself that they must have been begun about the year 435, the time when the basilica itself was finished, and since these doors exhibit figured panels not all wrought in the same style, M. Grisar, far from admitting that the sculptures are of different dates, tries to prove that several contemporary artists of different degrees of ability carried out the work. The subjects are allied with the iconography of Christian cemetaries: the series is not complete, since ten of the fables have been carried off by some one. These Roman doors deserve attention, too, because, earlier than any other to our knowledge, they exhibit the Crucifixion, and certain writers have seen in these doors the model of the celebrated door by Bernward († 1022) in the Cathedral of Hildesheim; but the resemblance is not really a striking one. The same thing may be said of the resemblance which they have tried to establish between the Roman doors and the chief doorway of the Cathedral of Spalatro, which dates from 1214. It is enough to say, however, that the doors of Sta. Sabina form one of the most important monuments of primitive Christian art.

Italy also boasts another very ancient monument of this class, one less known than the doors already spoken of, namely, the doors for the principal entrance to San Ambrogio, at Milan, which were removed in 1750 because of their ruinous condition; being at that time replaced by modern doors, incorporating certain portions of the originals. I have always considered these fragments as work of the eleventh century; but recently a student of the subject has shown that these sculptures date back to the same time as those of the door of Sta. Sabina. I can hardly give my adhesion to this new opinion emitted by Herr Goldschmidt. But, in any event, we are here in the presence of the remains of wood-carving of really venerable antiquity.

But it is not the wooden doors which in point of antiquity form the most remarkable group on the Peninsula. Italy could hardly be richer in bronze doors of the Byzantine type, and whoever would study this class of monument must, perforce, address himself to Italy. All writers who have given attention to Italian art of the Byzantine period have discussed the influences that this art exercised over the national traditions, some expanding and others restraining them. The truth is that this influence was not exercised with uniformity; a certain provincial admiration for Greek work has been remarkable, and even to-day is very evident. Elsewhere, it was less felt, and disappeared altogether at an early date. Aside from the city of Ravenna, in the North of Italy, the Byzantine influence was powerfully felt in the South, and an important witness to this is the many door-valves to be found in the Southern cities of Italy. This does not prove that there were none of these in the Northern and Central Provinces of the country, and here I mean the carved or engraved work, the most ancient specimens not dating back farther than the second half of the eleventh century. At this time, and in the twelfth century, bronze doors, particularly those executed in Constantinople, had an extraordinary vogue in Italy, but as soon as Italian artists attempted to imitate them the fashion ceased and, side by side with doors unquestionably of Byzantine origin, the Peninsula decorated itself with doors which betrayed their national origin. In this connection, that is to say, on the matter of the influence exercised by Byzantine work upon the authors of our bronze sculptured work, which I shall presently mention, one might write a long dissertation; but this is not the right place, or, at least, not the right time, for entering upon such a discussion. I will, therefore, limit myself to the most important facts, the ones best established.

There will be found amongst the illustrations the bronze door-valves of S. Zeno at Verona, one of the Northern cities of Italy, which fondly cherishes this venerable monument of the eleventh and twelfth centuries. These doors are really older than the time which we are studying, but they have not come down to us in their primitive state; for in the twelfth century they were very materially worked over, and of the ancient parts there only remain the left valve and some of the lower bas-reliefs upon the right valve. The carvings in general are crude, especially those of the eleventh century, but the general decorative effect of the door is particularly remarkable.

Nevertheless, any of my readers who might desire a model of door-valves of the twelfth century should not lose sight of the bronze doors of the cathedral at Benevento, in the south of Italy. The work in question is a monument of exceptional beauty for its time, and its general air and artistic worth connect it directly with the school of art which produced the celebrated doors of Andrea da Pontadera at Pisa, and Lorenzo Ghiberti at Florence, to such a degree as to enable one to affirm that the door at Benevento holds the same place in the art of the twelfth century as is held by the doors of Pontadera and Ghiberti. The door exhibits forty-three scenes from the history of the life of Christ; and this sacred composition is quite unique in the twelfth century. Never at this epoch had sculpture or painting composed so complete a story of the life of Jesus, and unfortunately the author's name is now unknown.

The doors at Benevento are sometimes compared with the two doors at Troia and Ravello, in the south of Italy, but if the details of the sculpture upon these doors remind one of those at Benevento the resemblance of the *ensembles* is less noticeable.

To summarize matters as much as possible: we shall make the acquaintance of a number of monuments, that is to say doors, some decorated with bas-reliefs, others engraved, the images being inlaid with metallic wire. The doors of the latter class are of the greatest antiquity: amongst them we find the doors to the Cathedral of Amalfi (1062), the Abbey of Montecassino (1066), of S. Paul. Outside the Walls of Rome, executed in 1070, at Constantinople, by the sculptor Staurakios; the door of S. Ange "sul Gargano" (1076) in the cathedral at Salerno (1077); the Church of the Saviour at Atrani (1087), and at the Cathedral Troia (two doors) 1119 and 1127; those by Barisano da Crani, in the Cathedral of Ravello (1179); the door at Pisa, executed by Bonanno Pisano, destined for the Cathedral of Monreale (1186), a work later than those by the same artist executed in 1180 for the cathedral of his natal city, which burned down in 1596, and the doors of S. Clement at Casoria (1191); of the Cathedral of Benevento, end of the twelfth century; and of S. John Lateran, at Rome (1196), etc.

As I have already said, in this series of monuments, rich though very incomplete (I give a list of doors later on), the doors have been executed either with images and ornaments incised and filled-in with gold or silver wire, or with bas-reliefs of small dimensions. Sometimes, as in the case of the door to the Boemondo Chapel, at Canosa, the Mussulman influence has the upper hand, and the ornaments are conceived in such a manner that they might properly enrich the doorway of a mosque. This should not excite surprise, as we know that we here deal with a province of Southern Italy dominated by the Normans, who had also conquered Sicily, giving to it a government and eclectic culture: and furthermore, in Sicily, the Normans found an old civilization — the Mussulman and the Greek, Byzantine art and the art of the Arab mixed together, at times one influence getting the upper hand, and at another the other, as in the Cappella Palatina at Palermo, with its ceiling enriched with stalactites, and I might say, as in the door at Canosa, if this had not arrived in Italy from Constantinople. Nevertheless, the fact of having accepted for a Catholic church an ornament of Oriental character is very significant, and the curious contrast is explained in the same manner in Apulia as in Sicily, the Government being the same.

Annexed is a short list of Italian bronze door-valves, naturally limited to the epoch of the Middle Ages, which has left us a great number of these works of art that have come down to us in a generally satisfactory condition. In addition to the name of the structure, I give the year or the epoch, the place of origin and, possibly, the name of the author; and I will add that this list of mine corrects inaccuracies in lists elsewhere published.

DOORS ENGRAVED AND INCISED.

Cathedral of Amalfi	1062	Constantinople.
Abbey de Montecassino	1066	Constantinople.
St. Paul, Extra Muros, Rome	1070	Constantinople.
Monte S. Angelo a Gargano	1076	Constantinople.
Cathedral of Salerno	1077	Constantinople.
S. Salvatore, Atraul	1087	Constantinople.
Chapel of Boemondo at Canosa	End of XI Century,	Ruggero d' Amalfi.
S. Mark's, Venice	1085	Constantinople.
S. Mark's, Venice	1112	Imitation by a Venetian Artist.

DOORS DECORATED WITH BAS-RELIEFS.

S. Zeno, Verona	X-XII	Century partly German work.
Cathedral of Troia	1119	Oderisio Berardo.
Cathedral of Troia	1127	Oderisio Berardo.
S. Bartolomeo, Benevento (destroyed)	1150-1	Oderisio Berardo.
Cathedral of Trani	1160	Barisano di Trani.
Cathedral of Ravello	1179	Barisano di Trani.
Cathedral of Pisa	1180 (?)	Bonanno da Pisa.
Cathedral of Pisa (destroyed)	1180 (?)	Bonanno da Pisa.
Cathedral of Monreale	1186	Bonanno da Pisa.
Cathedral of Monreale	End of XII Century,	Barisano di Trani.
Abbey of S. Clemente, Casoria	XII Century (?).	
Cathedral of Benevento	End XII Century (?).	
S. John Lateran, Rome	1196	Umberto and Pietro da Piacenza.

Now we have some slight knowledge of several of the Italian sculptors of the Middle Ages, three of whom especially interest us: Oderisio Berardo, Barisano di Trani, and Bonanno da Pisa; two

from southern Provinces, the third from Tuscany, that is to say, from one of the central Provinces. The last two named are sufficiently well known. The first, on the other hand, is almost a new name, even in Italy; yet some would, mistakenly, like to attribute to him the most magnificent door of the twelfth century, that in the Cathedral of Benevento; perhaps for the reason that this sculptor was a citizen of that city, for this reason being sometimes styled "Oderisio Beneventano." The fact that he is not the author of the doors at Benevento is demonstrated by a comparison of these door-valves with those of the Cathedral at Troia, which certainly are due to him: having been executed, as we have seen just now, the principal door in 1119, and the secondary door in 1127. I am sorry not to be able to halt longer over this subject; so, apropos of Oderisio Berardo, I will only add that M. Barbier de Montault has imagined that this Berardo (who is not Berardi, as we sometimes find him named) was a Frenchman of the name of Beraud.

Perhaps the door at Benevento was executed by the Greeks, for there is a tradition to this effect; and for my part, I am not unwilling to accept it, merely adding that it was quite possible that it should have reached Italy from Constantinople. Now, let us leave, for the present, the Mediæval epoch, and at the very opening of the Renaissance we shall find a door of admirable beauty, one of the most exquisite ornaments of the Italy of the fourteenth century, the work of Andrea da Pontadera, falsely styled da Pisa, he being really a citizen of Pontadera, one of the suburbs of Pisa.

Andrea da Pontadera influenced the artistic spirit and thought of his time in an exceptional manner. Born in 1270, he died at Florence in 1348; and during this long lifetime of seventy-eight years, we know with certainty of only a single work of his, the door with which we are now dealing. This is found in one of the secondary entrances of the Baptistery at Florence, and Vasari, who stated a great many facts which are not facts at all about our Tuscan artists, commits an error in refusing to credit him with the sole paternity of the Florentine door; but Vasari, as already has been remarked, would not deserve serious consideration if his statement had not been accepted by the eminent authorities Crowe and Cavalcasselle in the following words: "The chief work of Andrea," they say on page 3 of Volume II, "is certainly the bronze door of the Baptistery of Florence, in which, to the excellence of the composition and distribution due to Giotto, he knew how to add, with equal skill, a simplicity of expression, which admirably renders the chief idea of the subject chosen for treatment." This opinion cannot be for a moment sustained in face of the work. Andrea's gracious and tender style has no likeness with the profound, forceful gravity of Giotto's work. Moreover, Andrea began his work on the Baptistery door in 1330, when he was sixty years old, and no one can believe that an artist of his stamp, a real leader of his school, as he was, could accept a divided commission: a master of his stamp could not have been so humiliated. Well composed, as the door as a whole certainly is, it deserves examination more because of the many bas-reliefs, which divide it into twenty-eight panels; twenty of which are devoted to the life of St. John, and eight to the illustration of the virtues. The beauty of these images, the serenity and simplicity of the composition, make of Andrea's door a monument of extreme interest, a marvellous source of æsthetic pleasure. After examining this door, one understands the incomparable power of the two other doors of the Baptistery, the work of Lorenzo Ghiberti.

In Italy one cannot speak of bronze doors without having his thoughts turned to those doors which Ghiberti sculptured for two of the entrances to the Baptistery at Florence. The Baptistery has three doors, and every one remembers the competition which was held for the first door, which brought face to face several of the leading sculptors of Italy, artists as celebrated as Jacopo della Quercia, and Filippo Brunelleschi, the great architect. At the last moment the struggle lay between Ghiberti and Brunelleschi, who each executed a bas-relief which is still preserved in the National Museum at Florence; and everybody now knows that in 1403 Ghiberti received the commission for executing the door, which, still in a good state of preservation, commands our admiration, at the Baptistery. The composition of this door greatly resembles the door-valves by Andrea da Pontadera, so much so that they might be confounded, a fact which indicates how much the spirit of Andrea's genius influenced such a master as Ghiberti, whose second door Michael Angelo proclaimed worthy to be the doorway to Paradise.

The valves of this door date back to 1425, and in them Ghiberti abandoned the distribution of parts adopted by Andrea, and felt that it was fair for him to enter his bas-reliefs into direct competition with the painting of his times. He made paintings, as it were, out of his sculpture, surrounding each scene with an architectural or landscape background, richly staged. These doors were richly gilded, and here and there are still to be seen bits of the original gilding, but the present coloration of the doors is, to-day, that of bronze.

A matter discussed in these last years is the cause which might have destroyed the ancient gilding, and a very conscientious student declares that in modern times the doors were given a coat of paint. This statement, denied at first, has at length been admitted; for documents have been found which confirm the story that the doors of the Florentine Baptistery did receive a coating of bronze-colored paint: so we should be grateful to those who have made moulds of these doors, that we are, to-day, able to see traces of gold on Ghiberti's work, for the material used in making the moulds tore away the bronze paint, but left the gilding. This may appear doubtful to the reader, but I have the documents which support my statement.

Ghiberti's second door exerted a very marked influence throughout Italy, and the monumental bronze door of the basilica of St. Peter's at Rome, ordered by Pope Eugenius IV, from the Florentine architect and sculptor Pietro Averulino, called "Il Filarete" (died 1465 ?), follows the theme of Ghiberti's second door; so, too, does the little bronze door — a very pretty bit of sculpture — with which Jacopo Sansovino, about 1540, decorated the entrance to the sacristy of St. Mark's at Venice. As for the door at Rome, it is in merit far beneath what one might expect, when account is taken of the fact that it was intended for the noblest temple of the Christian religion. Life and character are lacking in these valves upon which Averulino had several collaborators, but amongst whom certainly was not Simone di Giovanni Ghini, as stated by Vasari.

I am sorry not to describe for the reader, at length, the door of the Castle Nuovo at Naples — very remarkable from the historic point-of-view — bronzework dating from 1462-68, and the doors of the north sacristy of the Cathedral of Florence, executed by Luca della Robbia, between 1447 and 1474, and originally ordered in 1437 from Donatello; and I much regret it, for the latter work is of the first class, sometimes forgotten, for the reason that Luca della Robbia's fame rests on his enamelled terra-cotta work. During his career Donatello did model the bronze doors of the sacristy of San Lorenzo in Florence, but the work adds nothing to the renown of this great master of the fifteenth century.

If we turn to the illustrations, particularly to the wooden doors at Lucca, Monteoliveto Maggiore, in the province of Siena, Parma and Pistoja, desire seizes me to discourse upon Italian Renaissance wood-carving, especially in that exquisite Tuscany, where bloomed the genius of Ghiberti, Donatello and Michael Angelo; for it is Tuscany, the home of so many admired sculptors, that produced a quantity of carved wooden doors, which decorated our monuments, even in the Middle Ages, as, for instance, the door-valves which adorn the Cathedral at Lucca, and the Baptistery at Pistoja. And since we have many works from this company of wood-carvers, a large part of whom were also architects, or sculptors, or painters, attaining sometimes the highest excellence with their works, we have a sufficient explanation for finding amongst these carved doors veritable *chefs d'œuvre* of composition. A certain architectural frigidity characterizes this class of doors, and the use of caissons, which is very often repeated in the ceilings of the halls and rooms in the time of the Renaissance, gives a rather monotonous aspect to our fifteenth and sixteenth century doors, which, nevertheless, in the course of the last half of the latter century, to some degree abandoned the rigid formula which I mention, and are enriched with *motifs* which Classicism would not admit.

As a sample of the transition between the Renaissance and the work of the Baroco period, we have the bronze doors at the main entrance to the Cathedral of Pisa. Here we perceive an effort of fancy which aims at an independence wholly unknown to the artists of the "high Renaissance," as my friend E. Muntz would say. The storied doors are generally attributed to John of Bologna or "Giambologna," the dean of the craft, to whom Italy owes a quantity of fountains. This master sculptor, born at Douai, France, 1524, and who died in Florence in 1681, must have received the order for these door-valves, and also for those which closed the two side doorways of the cathedral; but, although after rather indefinite data, the ascription of the work to Giambologna has been agreed to by most writers, recent investigations have shown that the actual part which the Flemish master had in these doors is really very modest, and might practically be left out of consideration. These doors were modelled by several artists of the school of Giambologna; such as Giovanni Caccini, Pietro Francavilla, Gaspare Mola, Angelo Serani, Pietro Tacca, etc. Moreover, the architectural design cannot be credited to the master, but should be attributed to Raffaello Pagni. This makes it apparent that an important series of sculptures at the end of the sixteenth century (the doors at Pisa were begun in 1596, and the master founder, Domenico Portigiani, who did almost all the founding during that period, died in 1602) were carried out by a group of sculptors most of whom had been almost wholly lost sight of.

A. Melani.

THE RELATION OF NATURAL TO ARTIFICIAL BEAUTY IN LANDSCAPE.

It chanced seven years ago, when we had to chronicle the untimely and particularly pathetic death of John Stewardson, that we had just noticed in *Lippincott's Magazine* the last piece of writing he had time to complete: a forecast of American architecture, and this we obtained permission to lay before our readers a few weeks later.

In the same way it happened that on the day we learned of the equally regrettable death of John Stewardson's friend and partner, Walter Cope, the mail brought us the report of the Fairmount Park Art Association, which contained the following lecture delivered before the Association recently, in all probability the last piece of writing by Mr. Cope: —

In announcing the subject for discussion this evening I feel that I owe you an apology for using such a broad, comprehensive title. Certainly, I do not intend to inflict on you a comprehensive discussion of the subject. It is too broad and touches too many details for me to attempt anything like a thorough treatment in one evening. "The Relation of Natural to Artificial Beauty in Landscape" is, in fact, a subject on which volumes might be written.

And first, as to the word "landscape," — I intended to use it in its widest sense as applying to any scene, whether that scene contain any element of man's handiwork or not. At the present time the subject of "landscape-gardening," "landscape-design," "landscape-architecture," or whatever it may be called, is receiving a great deal of attention, but in speaking of artificial interference with Nature, I should like to abolish the word "landscape" and use, instead, the words "out-door design," reserving "landscape" for that broader meaning which would cover every scene, whether natural, artificial or partaking more or less of both, anything, in short, which the eye may meet under the open sky.

At this age we are in the midst of great structural and engineering undertakings to meet the practical needs of our present civilization, with little thought as to their artistic expression. But times will change and the practical developments of applied science will some day give way to more definite efforts to make the face of the earth more beautiful. It may be a question only of a generation or two when the imagination of the multitude may cease to be moved, as it, undoubtedly, is to-day, by the great developments in transportation, the building of huge buildings and swift steamships, and by the constant improvements in electrical propulsion and communication. And when we shall have solved all these questions of applied science and are content with our achievements in that direction, we may turn our efforts to still greater achievements in an artistic way. To-day, those in whom the artistic sense is dominant are in the minority and this has always been so and probably always will be. But to-day differs from past ages in this fact, that the great majority of people in this age do not really care for artistic expression, do not care as much for the beautiful as they do for what we commonly call "the practical." To-day the artist occupies a relation to the great mass of humanity almost analogous to that which the mediæval alchemist or scientist held in the day when it was the artist who counted, and who captured the applause of the multitude. It is true that the support of the multitude is constantly increasing, but as yet this support has not swept everything before it, and a utilitarian and purely practical tendency is still dominant. The artist of to-day is not in need of better criticism. He has as good criticism as any age has produced, but he is in need of a greater amount of criticism and of the backing of the majority of the people, the criticism of the masses which finally, if not immediately, condemns the inartistic and upholds that which is sound and true in art.

Whatever scene our eyes may light upon, whatever landscape we may contemplate, there can be only two factors — two agencies — which determine its effect upon our minds, upon our sense of the beautiful — Nature and Man. Nature, of course, is a very wide term, but we know what we mean. It is the supreme, the eternal, the ever-present factor. We cannot escape from it entirely if we would, for even man in his works is governed by Nature's own laws. No one of them can he undo or abrogate. The primary laws of physics must govern everything which he builds, and the artistic expression of his building must reflect an acknowledgment of natural laws. But in distinguishing between these two agents, I mean to refer to Nature as that which she does without the aid of man; what she would have done had man never lived upon the face of the earth. On the other hand, in many scenes and many things which we love to look upon there is predominant the other agency, and our delight in its contemplation at times transcends even that which we feel in looking upon Nature; the thought that this stone has been hewn and set, this building has been reared, this path has been cut, these trees have been planted by *man* and to satisfy man's needs and ideals. Perhaps no two of us could agree upon the intensity of pleasure derived from the contemplation of a great cathedral, on the one hand, or the majesty of a rock-ribbed mountain, or the boundless sea, upon the other, nor is it worth while that we should agree. To some of us Nature appeals more than art, though I believe that to most of us each appeals with almost equal force, according to our varying moods.

It follows, then, that if we are to arrive at the true sources of artistic enjoyment we must cultivate and love and study first of all *Nature* and after that man's history, man's ideals, all, in fact, that has led him to express his wants, his aspirations, in physical form. This last is nothing more nor less than the study of architecture in its broadest sense. For all that man builds with an eye to use and beauty is architecture in the sense that it is governed by one system of principles and laws. From time immemorial man has built houses and temples and bridges, has hewn roads and laid out gardens and wrought whatever pleased him upon the face of the earth to satisfy his needs, material and spiritual. And from time immemorial it has pleased him, and it pleases us to-day, and will always please our descendants, to follow certain methods, certain principles of dimension, direction and proportion in that which we lay out and build. These methods are, no doubt, deduced primarily from our innate sense of natural laws. But it is scarcely necessary to go into the source of them. Suffice it to say that it is an indisputable truth that man prefers to set stones level, to build walls straight, or, at least, symmetrically curving, to make level places on which to stand or walk, whether they be floors beneath a roof or terraces under the open sky. His sense of mastery over Nature is expressed in doing things not as Nature would do them. Nature upheaves and splits and tumbles down her rocks. Man hews them into blocks and sets them level and true and rears them into walls. So it always has been — so it ever will be.

In every landscape, then, these two elements must remain distinct. We cannot absolutely unite them nor deceive ourselves into thinking that we can. We cannot modify to any extent worthy of consideration the process of natural growth, or at least such modification can be but temporary. Nature is absolutely continuous and persistent. We must then regard ourselves only as intruders — invaders. It is true that we can interfere with Nature, but it is my purpose to point out that it is not as interferers that we should regard ourselves. As invaders we may, for we could not avoid the position if we would, unless, indeed, we return to absolute savagery.

About the middle of the century just passed, there grew up a school of landscape-gardening, so-called, which was, perhaps, a natural reaction against the extreme and lifeless formalism into which architecture had descended. This school made a complete revolution in the principles which had always before that time governed all artificial interference with the face of Nature. It did not propose to do merely what man had always been pleased to do in the way of laying-out and building and planting, but instead proposed rather to imitate and follow Nature on the lines which she has always reserved to herself. This school still has its disciples, and the results of its work are all about us and have caused, to my mind, a most deplorable subversion of the laws and the principles upon which beauty in landscape must depend. Nature is entirely able to do without the aid of man, and it is equally true that it is impossible for man to imitate Nature without making himself and his work more or less ridiculous. When he attempts it, he must cast to the winds all the methods, all the principles which he has developed in centuries past, and he must play at his game as a child would play at horse. But every once in a while he has to leave his play to attend to the serious matters of life, to build a house or a flight of steps, and these he has to do on the same good old lines that have always prevailed in architecture. He may build his silly little rockeries in would-be imitation of Nature and cut his meaningless winding walks, but he cannot cease to build civilized buildings, he cannot be content to live in caves or rude, shapeless huts.

The moral of all this is, let Nature alone, except where, to satisfy your own practical needs, to satisfy your own ideals of the beautiful, you invade her sacred domain with works that are frankly and freely designed upon lines not imitative or in competition with her, but rather on lines which have commended themselves to man as necessary, reasonable and beautiful from his own particular point-of-view, lines which embody all which he has ever developed as an expression of his own mastery over the earth.

Can we, then, intrude upon Nature in anywise without destroying its charm? Decidedly we can. We may invade Nature with our works and find the result all the more charming; and, in the same manner, Nature may, and does, invade our works only to increase their charm. But the source and reason of our invasion must announce itself frankly. We must feel that this space through the forest has been cleared and levelled in order to meet some human need, that it reminds us of the existence of man and enforces the *human* element, and so serves as a foil or contrast to Nature's work. To look at the other side, what can be more beautiful than the work of man overgrown by Nature — the ruined abbey wrapped in ivy, or the old Italian garden, where the balustrades are half smothered in vines and the vistas down the long paths and terraces are framed between giant cypresses, growing without restraint, long after the builders of those stately balustrades and fountains are forgotten!

Nature, in her own wildness and ruggedness and majesty, we cannot rival, and she, on her side, makes no attempt to rival us. The majesty and beauty of the lonely mountain-side we cannot create, but we may invade it without destroying its charm. Nay, more, we may introduce the human element in a way only to heighten and increase that charm, and it is just where those two elements meet, each in its purity, its frankness, its directness, that we often find the very highest and keenest sense of the beautiful. Can anything be compared in beauty with the views from out the terraced gardens of the Italian lakes, across the deep, smooth surface of the water to the great mass of the Alps beyond? Is a flower ever more beautiful than where it has grown in the crevices of a mouldering ruin? And which is most desolate — the city street, devoid of one touch of natural growth, whether of leaf or flower, or the unbroken expanse of a trackless plain? We have our moods when each of these may please us and Nature has every advantage both in majesty and beauty, but it remains that man is a social being, and, as a rule, he loves to be reminded of the existence of his fellow-man both past and present. He will never resent the evidences of that existence if they occupy a reasonable and proper place.

To come, then, to details: Where and how may we invade Nature? First, we *must* build our houses, our cities, we must bridge our rivers and ravines, we must lay out our roads, even our railroads, and we must go even farther. We must, if we are to satisfy our sense of eternal fitness, make our terraces and gardens where, while asserting our dominance, we can hand over a larger share to Nature's decoration of trees and flowers. Nay, we can even take these trees and flowers and arrange them in formal lines, as we might build a wall, according to our own ideals of what man should do. Nature would never do so of her own accord. An avenue of trees planted at regular intervals, or a trimmed hedge, is as much and as confessedly artificial as the road which they skirt. The box-borders of a garden are, in a sense, as architectural as a stone balustrade. They are simply the works of man in a living medium instead of in a dead one. It is merely a question of how much we shall do of this sort of work, how much is appropriate in a given place to emphasize

this mastery of man over Nature. Manifestly, it must depend upon the dominance with which we wish to assert, the extent to which we wish to remind ourselves of, the human element. A planted avenue has no place in the midst of an uninhabitable plain. It belongs as part of a house, some human arrangement made for man's use and delight. But in proportion as we separate ourselves from centres of human life should we restrain ourselves in making artificial arrangements of planting. A garden is nothing but a great out-door room, a house, so to speak, under the open sky, in which the levels, the width of the paths, should be determined by the same principles of design as we would apply within our houses in the arrangement of our rooms, but whose decoration and coloring, so to speak, are turned over to Nature. And a park made for the use of the multitudes of the city will, in the same way, find its greatest beauty in allowing man's work and Nature's to follow each along its own lines. Why is an avenue of great trees more majestic than an equal number of trees equally spaced, but artificially dotted at random over a given area? The avenue in its arrangement, in its spacing, is *man's* way of arranging trees. It is like a peristyle of great columns; but an equal number of trees equally spaced and yet at random is neither man's way nor Nature's. It expresses neither one thing nor the other, either to the lover of art or to the lover of Nature. Nature does not plant her trees like a crop of corn at suitable intervals and of equal age and size, and it is only where there has been an unsympathetic and unnatural and Philistine interference on the part of man, whether in planting or in cutting down, that we find trees grouped aimlessly, but at equal intervals.

Nature does not build river-walls or bridges or roads any more than she does houses, much less does she make railroad cuts or embankments. What, then, should be our rule in dealing with these? The cuts and embankments for railroads our landscape-gardeners have, fortunately, generally given up in despair. Surely, if not discouraged, Nature will take better care of these than man can possibly do. She will gradually shroud them in trees and thickets and hide the ugly bare gashes that the hand of the engineer has made. Our Wissahickon drive is a beautiful example of this. Did it ever occur to you how frightful, how hideous the Wissahickon must have been when that drive was made — the rocks tumbled down into the stream in great masses? Left alone, Nature has made it utterly beautiful. But what of our river-walls and bridges? Do you think to make these beautiful by building them carelessly, roughly, on lines that are not true and perfect and beautiful architecturally and at the same time cut off all chance for Nature to hide their naked ugliness? Or should they be built as we would build any work which we are pleased to call a true work of art, a true masterpiece of architecture? Shall they be carefully designed and laid out on perfect curves as we would a great building? Certainly, — why not? And the only limit in the matter of costliness and perfection of finish should be the predominance which we wish to give at a given place to the human over the natural element. The well-hewn and graded slopes and levels and bridges of a great mountain-pass may rightly be treated as merely utilitarian, laid out on the lines of the most utter reasonableness, the best engineering, — just, for instance, as the Wissahickon drive, — without undue expense of finish or perfection of curve. Nature will take care of them if she is left to herself, and as time goes on the ravage of man's hand will be lovingly hidden by moss and leaf, and there will be nothing to mar our sense of the reasonable and beautiful. But in a great city or its park or within the well-kept precincts of a country place close to the house, where man must be constantly reminded of his own existence, where people congregate, there it is appropriate that the greatest architectural perfection, the most careful study of design, should be given to every artificial work. We are so trained to think that what we build in the shape of a house must be carefully studied by men who have given their lives to the subject, whose life-work it is to design, that in this last century we have forgotten that all building, all artifical interference with the face of Nature, as I said before, is a part of the same thing, — is only the visible expression, — the physical expression of man on the face of the earth. And the same principles of design that determine the proportions of a façade, — whether an arch shall be a little higher or a little wider, — those same principles govern the dimensions that we would spread out on the face of the ground. A flight of steps out under the open sky is just as much a matter of nice design and proportion as a façade of a building. We are not used to thinking so, especially here in this part of the world, but I believe we are coming to it, and every one did think so before the beginning of the century just past. All out-door design was considered as only a part of architecture, and the same nicety and skill applied to it as in the building of houses. The idea is not only unfamiliar to us of the present day, but it is one I have myself found very hard to put into practice. We have all of us grown up in an atmosphere of believing that the work a man does with pick and spade is an entirely different thing from what he does with hammer and saw; but it should not have been so considered.

But let Nature, so far as she will, clothe this work of ours — whether it be simple or elaborate — in her own way, and still the effect will be more and more beautiful: The two elements will stand in stronger and stronger contrast to each other, not in discord, but in utter harmony and agreement. I by no means urge elaboration or overmuch ornament in that which we do. In this we should be governed by the same rules of good taste and restraint that should characterize every architectural work.

In this country we have been so affected by the school of landscape-gardening, to which I have referred, that we are afraid of the doctrine of formalism. The American of to-day, when he sets about improving the landscape, is very apt to think that he should confine his formal work to buildings, and, after that, pitch into Nature with spade and axe and pruning-hook and impress upon her the fact of his existence by thinning out trees in one place, spotting young trees aimlessly about in others, laying out meaningless and meandering roads and paths and building rustic bridges and what not, with the idea that he is showing his sense of harmony with Nature. If he builds walls or outlying works in stone he feels called upon to give them what he terms a rustic appearance. He fits their tops with jagged pieces of stone, paying but minor heed to lines and levels and to the question whether any wall is needed or not. Now, there never was a piece of stone-work that suffered from being too well and decently laid, and there never was a path that looked the better for curving to a given spot when the curve was due to no natural obstacle and did nothing to make the grade easier. And when we come to the cutting and planting of trees as practised, perhaps more particularly in this neighborhood than any other place that I know of in the world, I can scarcely restrain a feeling of bitterness. What other part of the world has been more richly endowed by Nature with noble native trees than ours, or what more beautiful forest undergrowth can we find than that which springs naturally where it is allowed in the woods of Pennsylvania? Why should we insist on discarding our native growth in favor of trees which are not at home in our country-side and never will be? The pointed spruce, which belongs among the rocks and precipices of the mountains or the rocky coasts of New England, has no sympathy with our softly rounded hills — its aggressive, pointed form needs the contrast of huge rocks and cliffs to harmonize with any open landscape. Can the poor, insipid maple (that is perhaps a little hard) compare in beauty with our sturdy native oaks and chestnuts and sassafras? And as to undergrowth, — why do we insist on cutting off the supply which Nature is always providing of young trees that will, in time, take the place of the taller ones as they die? And why, too, in cutting down our thickets, do we deprive the birds of their nesting-places and the ground of its natural store of moisture, so necessary to the health of trees? There is a good old word in our language which is becoming obsolete in this part of the world, and the fact bespeaks our lack of appreciation of what Nature will do for us if we let her. It is the word "copse," or "coppice," — that natural tangle of trees, little or big, with broken outlines against the sky, a mere fragment of woodland, perhaps, but in itself offering a thousand beautiful studies in rounded or broken outline of twig and foliage. Where can we find more lovely masses of broken skyline, of color, light and shade and blossom than along our untouched hedge-rows? What has the nurseryman given us to take the place of these where they have been destroyed?

If, then, we are to invade our woods, let it be only with wood-paths, and let these be as modest as may be where few travel over them; and where the multitudes must needs enjoy the woods, let good, wide, decently levelled and decently kept paths be run. If it is distressing to see a rough railroad-cut or an embankment in the midst of beautiful mountain-scenery, it is equally so to see a wood overrun by people. I know of nothing more unpleasant than a picnic-grove. There is in it only the feeling of desecration. Where people, then, must congregate beneath the shade of trees, let broad walks be provided in a decent and formal way, a way to acknowledge man's self-respect and, at the same time, his reverence for Nature, and let those parts of the woods not open for such walks be kept sacred, if possible, from human footprint or touch.

If trees must be planted (I except avenues), plant them as Nature would, not at "suitable" distances and each one just as big as the nursery will afford, but sow them hit or miss as Nature does and close together or far apart as chance may place them, and not all of a size. For, if you are to grow a wood or a grove, you must leave to Nature to determine which young tree shall outstrip its neighbors. If you cannot persuade yourself that this will produce a beautiful effect, go into any wild natural wood and see how the roots of even the finest trees are interlocked and their trunks almost united in places. It is by this very overcrowding that Nature produces her most beautiful effects of light and shadow, of contrast; it is the first cause of all picturesqueness in bough and foliage. *Luxuriance* of natural growth should be our aim.

On the barbarous practice of lopping trees I need scarcely comment, but let me make another protest. Having planted flowering shrubs, why should we trim them into rounded balls every winter and thereby cut off most of the bloom-bearing wood? In their proper places the trimming of hedges and box-borders and yews into stiff architectural shapes is one thing, but to trim shrubs, which are beautiful because they bear long, feathery sprays of flowers, has no excuse. It is generally from last year's wood that the flower-bearing shoots spring, and to cut these off each winter means little bloom in the following spring or summer. We need waking up in some of these things. All about Philadelphia this is the practice among the gardeners. People who believe that they have beautiful places and have set out plants to grow allow their gardeners to sweep over them every spring and trim these feathery shrubs into round buttons; it is senseless, aimless, ugly, unheard of! I do not know where it came from, but it certainly prevails in the districts around Philadelphia. If flowering shrubs *must* be cut down, well and good, but take them down entirely, just as you pick out a fern from the midst of a group without marring the beauty of the rest. Trimming

a flowering shrub is as absurd as trimming a maiden-hair fern with a pair of shears.

To sum up: I would urge simply that we take Nature more thoroughly as we find her and as she would be if we let her alone, that we treat her with more respect and allow her free sway where we acknowledge her right to exist at all, and that in all we do of artificial work, whether it be to build houses, to level and open roads, to lay-out walks and gardens, we do all with an eye to the eternal fitness of things, not hoping to improve upon Nature, but merely to make beautiful works of our own. These cannot, if they are really beautiful and reasonable, ever interfere or mar to any extent the beauty of the landscape, but will only serve in the long run to heighten its interest and charm. If this country should ever become depopulated in future ages, let the stranger wandering over it feel not only the beauty of its natural hill and forest and river, but, as well, the beauty and perfection and dignity of all that we have left behind us.

Before closing I have just one suggestion to make — one thought to lay before you — and I do it with all due deference, but with the greatest seriousness. The Fairmount Park Art Association has, it seems to me, devoted itself exclusively to only one field of art — to Sculpture — and that, one of the most advanced and developed and intellectual phases of art — one of the finishing touches. "Fairmount Park" and "Art": these two words are associated in my mind in a way which finds, I confess, a very incomplete reflection in the work of your Association. There is a far wider and more appropriate field for art in Fairmount Park than you have ever touched. The fact is that, until there is a place that needs sculpture for its decoration, sculpture is merely an intrusion. To place miscellaneous statues without reference to any scheme architectural in its broadest sense, as I have endeavored to explain, is treating neither sculpture nor Nature fairly. There should be the connecting link, "The Out-door Design," as I have called it, which leads up to sculpture and requires sculpture as its highest accent. What you have been doing is too much like varnishing a board before it is planed or before it is made into anything. With all due deference I would like to suggest that your Association should take up the study of the truly artistic possibilities of Fairmount Park with perhaps greater reverence for Nature, and for art as applied to it, and less concentration upon sculpture alone. The artificial works that have been perpetrated within the limits of Fairmount Park have, unfortunately, been executed with little artistic thought and skill. They are, to be frank, many of them abominably bad and a bitter disappointment to those who know that beauty instead of ugliness might have been created in many places. Nature has been desecrated in many ways, both in laying-out and planting, while the finer touches have been omitted almost entirely or left entirely to the work of your Association. Cannot the Fairmount Park Art Association stand for an insistence on more artistic work in Fairmount Park in the way of bridges, walls and roads? Must we from year to year look on while the beautiful wild banks of the Schuylkill are lined with vulgar river-walls, built with less beauty of curve or precision of line than a railroad would use and yet dressed in ostentatious fringes of jagged stone? I know, of course, that your work is conducted quite independently of the commissioners of Fairmount Park, and that the ill-judged and badly designed works within the limits of the Park are not your work. But, all the same, you have taken upon yourselves with your name a responsibility which the public of today, and, still more, of the future, would hold you to if it could. Can you not formulate, with all the means at your command and with all the weight which your membership carries, some plan by which the great possibilities of the Park may be realized? While you are paying your thousands to artists the city is paying its tens of thousands to workmen. Is there no method by which these two forces may be brought to work in one common channel to one common end?

WALTER COPE.

SOCIETIES

THE LATE JOSEPH M. WILSON, MEMBER OF THE PHILADELPHIA CHAPTER, A. I. A.

RESOLVED, That in the sudden and lamented death of Joseph M. Wilson, a Fellow of the American Institute of Architects, we are called upon to mourn the loss of a man distinguished by high professional aspirations and attainments, a dignified and courteous gentleman and a citizen of distinction. As members of the Philadelphia Chapter A. I. A. and as individuals, we mourn his loss and honor his memory.

Mr. Wilson was elected an Associate of the American Institute of Architects in 1871, and a Fellow in 1876. During his whole connection with the Institute he aided with voice and pen in the advocacy of the highest ideals of professional practice and honor. Our sympathy is duly tendered to his family and business associates in their bereavement.

Resolved, That this resolution be entered upon our records and copies sent to his family and to the firm of which he was for many years the honored head.

THE FAULKNER HOSPITAL, WEST ROXBURY, MASS. MESSRS. KENDALL, TAYLOR & STEVENS, ARCHITECTS, BOSTON, MASS.

THE problem presented to the designers of the Faulkner Hospital, a fireproof suburban hospital of about fifty beds, was a somewhat unusual one, as the only possible location on the lot purchased was on a slope, to the south, of about 20 feet to the hundred.

A "pavilion" plan seemed most desirable, and especially so in this case, as the funds at hand precluded the possibility of building more than two-thirds of the proposed plant at first, and the unusual slope of the ground necessitated the combination of the administration, operating-department, nurses' home, service, heating and laundry in a single narrow building.

This central combination building is four stories in height and, as the pavilions can properly be of but two stories, the exterior was studied to produce a low domestic effect — the different departments disposed on the various floors as shown in the accompanying plans, with the kitchen, laundry and servants' rooms on the top floor.

The general scheme is to use one pavilion for male patients, the other for female, with the surgical cases on the first floor, and the medical cases on the second floor. Still further classification is possible with the isolation and private rooms provided.

The construction is of steel and concrete, vaulted walls, steel studding, and hard plaster. Exterior of water-struck hard brick, wide joints of white mortar, so laid as to produce the diaper shown. Trimmings of granite, terra-cotta and copper.

The floors are of maple, marble and terrazzo; finish of ash, and everything is of the most solid and substantial character.

NOTES AND CLIPPINGS

COLORING MUSEUM CASTS. — The Art-director of the Bremen Museum has astonished his fellow-citizens by coloring and painting his immense collection of casts in imitation of the marble or bronze of the originals.

The work has been done with the sanction and help of Professor Ruedorffer, of Munich, and according to the *Kunstchronik*, the result has been greatly to enhance the interest of the collection, and relieve the monotony of long lines of white plaster figures. — *N. Y. Evening Post.*

Heating Shops by the Fan System. — Henry I. Snell, writing in *Cassier's Magazine* on the fan system of heating, says that the first shop heated by this system was furnished in 1873, and that now nine-tenths of all the large modern shops are using it. With it a fan-blower or an exhausting-fan of suitable design is located at any desirable place within or without the building. At the discharge outlet of the blower, or the inlet side of the exhauster, a proper amount of steam-heating surface is placed in the form of coils, cast-iron sections with vertical pipes of steel, or any of the various forms of cast-iron radiators, enclosed in steel-plate casings or brick chambers and connected with the fan. At the discharge outlet of the fan should be a main warm-air duct from which will lead various branches, properly designed and located, with outlets for the most efficient distribution of the warm air. For supplying the heating coils live steam may be furnished from the boilers, or exhaust steam from the engines driving the works. The power for driving the fan may be supplied by a steam-engine, electric-motor, or belt transmission from main shafting. The cost of installing a fan-system is very often less than the instalment of a system of direct or indirect steam-heating, or hot-water heating, of equal effectiveness. The determining quantity in the cost is the amount of galvanized-iron air-distributing pipe, which is a varying quantity in shops of the same size and exposures, depending upon the existence and location of party-walls or office-rooms, and the location of the apparatus.

Italianized English. — The opening of the tunnel in the heart of the Eternal City, through the Quirinal Hill and under the royal palace, has brought forward the interesting question of what it shall be called. At first the English word tunnel was used, as a matter of course, the pronunciation being peculiar, but still recognizable, until a cry was raised by the purists, who insisted that as there was an Italian word it should be used. The choice lay between "galleria" and "traforo." The *Giornale d'Italia* opened a kind of referendum among the best-known authors and literary people, the result being that the majority were for "traforo," which means "through a hole." While in England foreign words, especially Italian ones in music, are accepted in their entirety, such as "crescendo," "piano," "allegro," etc., in the Peninsula they are always Italianized, which produces some most ludicrous results. For instance, beefsteak has been turned into "bistecca," which is applied not to the kind of meat, but to the mode of cooking it, so that one demands beefsteak of veal without a smile, the waiter not having the remotest idea that you are using or misusing a foreign word. Another term is "tramway," which has been made over into "tramvia," and, of course, means the same thing. Then there is meeting, which has become "miting," and to which another syllable has been added, making "mitingaio," which signifies a man of high-flown language who impresses the masses. — *Pall Mall Gazette.*

Even a Draughtsman can be a Hero. — In the crowd that watched the fireworks display in Madison Square Park on the night of election day was a man of fifty, a draughtsman, employed by a contracting-company of this city. He was near the men who were setting off the pieces, and when the explosion occurred, a big piece of one of the iron mortars tore off one of his legs. Panic and confusion followed the disaster. There was no immediate aid for him, nor for a small boy lying near by. The man called for aid for the child, but, though using four languages, he could not make himself heard or understood. He lay there until a dying man called for a priest. No one else responding, the injured man dragged himself over the intervening distance and managed to raise the poor fellow in his arms, while a priest, opportunely arrived, administered the last rites. Then the unnamed hero patiently lay, waiting for assistance, meanwhile pressing his thumb on the severed artery. After a half-hour's delay, he reached the hospital. There the surgeons said that his life was saved only by his cool precaution. At the hospital the patient was cheerful, even joking over his maimed condition. Only one thing worried him; he feared he would lose his situation. Learning of this, his employers promptly sent him word that his place would be kept open. Now, the only trouble they have on his account is because of his constant requests that some of the office's work be brought him at the hospital. He had been engaged on an important set of drawings, and to pacify him, he has been allowed to work at a few of the plans while lying in his cot. — *N. Y. Evening Post.*

Incandescent Lamps. — The manufacture of an incandescent electric-lamp is of special interest because many of the operations have heretofore been regarded as trade secrets and carefully kept from the public. The delicate filaments which produce the light are formed by squirting a paste made from cellulose (wood pulp) through dies, from which it emerges in the form of fine threads, which when dried are tough and flexible. These threads before they are dry are formed into the desired shape. They are then packed in carbon-dust and subjected to intense heat for many hours. The cellulose is completely charred, and the filament now practically consists of charcoal. It is then suspended in an atmosphere of hydro-carbon vapor, in a vessel in which a partial vacuum has been made, and a current of electricity sufficient to bring it to incandescence is sent through it. This decomposes the hydro-carbon, and a carbon-soot somewhat resembling graphite is deposited on the filament. This is technically known as "flashing." After this treatment the filament has a metallic lustre resembling polished steel. The glass-bulbs are blown in moulds to secure absolute uniformity, and as they come from the glass-house they are perfectly smooth at the rounded end and have a long open neck. To the rounded end is fused a short length of glass-tubing opening into the interior of the bulb. This is subsequently used for connecting the bulb to the exhaust pump. For making the connection through the glass between the carbon-filament and the wire the most satisfactory material is platinum, because it adheres firmly to fused glass and because it expands and contracts at the same rates. If this were not the case when it got hot through the passage of the current it would either expand more or less than the surrounding glass, and either break it or make a space through which air would leak. So through the little glass stopper which will eventually project down into the neck of the bulb are fused two platinum wires. This stopper, which has a flange at one end, is now called the mount or stem. Next, the filament is fastened to the ends of the platinum which projects from the stem. This is accomplished by means of a special cement which will stand a red heat. Over this paste is deposited a layer of carbon. The paste is then dried in an oven, and the stem, with its attached filament, is fastened onto the bulb by fusing the flange on its upper end about the neck of the bulb. After this joint is carefully tested to be sure there are no leaks, the exhaustion of the air is accomplished by means of a mechanical air-pump, the last traces of gas or air being removed from the bulb by chemical means. When the vacuum is sufficiently high the tube through which the air has been exhausted is sealed off by means of a small lamp, leaving the small round tip seen on the spherical end of the finished lamp. The lamp is now practically completed, and is sent to the testing-department. Here it is subjected to a series of severe tests before it is considered ready for the market. If it passes these successfully the base (the portion by means of which it is screwed into a bracket) is cemented on, and the completed lamp goes to the shipping-department. — *The Electrical World.*

Streetside Trees in Washington. — With the same care that a Tammany district-leader studies the voting strength of his bailiwick, Col. John Biddle, the Engineering Commissioner of the District of Columbia, enumerates the trees in the public streets. This year the total number of trees residing in the district highways was 84,487. The death-rate of trees for this year was 647; the new trees set out numbered 2,600. The varieties used for planting this year were elms, lindens, Norway, silver and sugar maples and pin and willow oaks. A nursery containing 22,000 seedlings is also maintained for the purpose of providing a supply of trees for annual planting. Washington, more than any other American community, is a city of trees. The broad avenues and low buildings combine to offer the least possible amount of protection from the Southern sun, and only the shade of the numberless trees makes the streets tolerable in summer. Of late years the asphalt paving has caused a great mortality in trees. Not so many years ago Pennsylvania Avenue, from the Treasury Building to the Capitol, was a finely-shaded promenade, along which Congressmen walked almost in procession up to the Capitol in the morning and back in the afternoon. Those trees are gone now, and the pleasant morning stroll is impossible when the sun begins to strengthen. — *N. Y. Tribune.*

Anthracite Coal. — Anthracite coal, which we are all so anxious to get just now, was, less than a century ago, when the first efforts were made to market it, denounced as a fraud. The people of those days declared it was impossible to burn such "stone." At the close of the eighteenth century, in 1791, the Lehigh Coal Company tried in vain to sell in Philadelphia the new fuel which had been found on its property in Carbon County. Several attempts were made to burn anthracite, but for a long time the results were uniformly unsatisfactory. Finally, in 1815, the secret was accidentally discovered. Tests had been made in a rolling-mill at Schuylkill. After repeated attempts to make it burn by means of frequently raking the fire, the workmen gave up the experiment in disgust, filled the furnace with the worthless "black stones" and left it. Returning a few hours afterward they were amazed to find a fierce fire with a terrific heat, and thenceforward the problem of burning anthracite was solved. But the people were slow to believe that it was possible to get heat by burning the black stones. As late as 1833 one Charles Miner wrote as follows: "While we push forward our labors at the mine, hauling coal, building arks, etc., we had the greater difficulty to overcome of inducing the public to use our coal when brought to their doors, much as it was needed. We published handbills in English and German, stating the mode of burning the coal, either in grates, smiths' fires or in stoves. Numerous certificates were obtained and printed from blacksmiths and others who had successfully used the anthracite. Mr. Cist formed a model of a coal stove and got a number cast. Together we went to the several houses in the city and prevailed on the masters to allow us to kindle fires of anthracite in their grates erected to burn Liverpool coal. We attended at blacksmiths' shops and persuaded some to alter the 'too-iron,' so that they might burn the Lehigh coal; and we were sometimes obliged to bribe the journeymen to try the experiment fairly, so averse were they to learning the use of a new sort of fuel so different from what they were accustomed to." But even these methods were slow to overcome popular prejudice. It was only when, through a sudden rise in the price of charcoal, the manufacturers began to use anthracite that the new fuel found its way into favor. — *Toronto Mail and Empire.*

The Reichsrath Fountain in Vienna. — The grand fountain at the approach to the Reichsrath in Vienna, the imperial Parliament House, has recently been finished. From the centre of a great basin of marble rises a pedestal with a colossal figure of Minerva. Against the four sides of the pedestal are groups of figures larger than life. In each group two figures represent Austrian rivers, so that eight rivers in all are symbolized. Between each pair a stream of water pours from a jar into the basin, while behind are genii and cupids. — *N. Y. Evening Post.*

NOTES AND CLIPPINGS. 103

THE newspapers call attention again to the enormous cost of modern dwelling-houses in New York, which now far surpasses anything known in London or Paris. In Paris, although, as in New York, the population is divided between the many poor and well-to-do people who live in tenement-houses or apartments, and the few rich who have a whole house to themselves, the Parisian "hôtel," or single dwelling-house, is a much simpler affair than the New York mansion. For a building-lot, twenty-five feet wide and one hundred feet deep, in the middle of a block on Murray Hill, which still continues to be the fashionable quarter, seventy-five thousand dollars is considered a low price, and few houses are built on such lots which cost less than one hundred thousand dollars, above the value of the land; while, within the present year, sixty-seven houses have been built, valued at from five hundred thousand to six hundred thousand dollars apiece. Two causes seem to favor this enormous increase in the cost of dwellings for rich people, and for land suitable for them; one being the great influx into New York of very wealthy people from all parts of the country, who come there to enjoy the luxury of the second city in the world, and are ready to pay almost any price for a foothold; while the other is the very limited area in New York which is really desirable for the best class of houses. In Paris, the newcomer and his family can settle in the Faubourg Saint-Germain, or in almost any part of the large district between the fortifications and the river, west of the Madeleine, or in the "annexed district" of Neuilly, without feeling themselves cut off from fashionable society; and the proposed demolition of the fortifications will still further extend the fashionable district; but, in New York, the pleasanter parts of the town are surrounded by the tenements of a vast and increasing foreign population, contact with which is fatal to the pretensions of any family to fashion. So sharp is the boundary-line between the fashionable quarter and that occupied by the foreigners that a New Yorker can almost infer the nationality of an unknown person from being told where he lives. Of course, there are comparatively inexpensive regions in New York where artists and men of letters can live together, just as Paris has its Latin Quarter; but the New York Bohemia is by no means so pleasant as that of Paris, and the people who live in it must submit to be elbowed at every step by unsavory Poles, Russians or other foreigners. To sensitive persons, who object to such contacts, Fifth Avenue and the neighboring streets form, therefore, a sort of Paradise of respectability, in which every one desires to take refuge who can afford to do so; and, as there are now plenty of people who can afford themselves such a luxury, they, practically, bid for it against each other.

THE New York newspapers are, perhaps, unnecessarily astonished at the price just paid for the Trinity Building, which brought one hundred and ninety-eight dollars per square foot; and some of them indulge in rather wild dreams of the future of Manhattan real-estate. As a matter of fact, the price paid for the building was rather low, considering the advantages of its situation. Mr. Mills is said to have paid about three hundred dollars per square foot, twenty years ago, for land in the middle of a block, on Wall Street, for the sake of giving his Broad-Street building a Wall-Street entrance; and the Trinity Building, fronting on Broadway, almost at the head of Wall Street, with another street in the rear, and Trinity churchyard on the south, should be intrinsically worth more per square foot than any property on Wall Street, and, perhaps, more than any other estate in New York. In the same way, the Park Street Church estate, in Boston, recently sold at about one hundred and forty-four dollars per square foot, was a bargain for the purchasers, who, although they are restricted as to the height of the building that they can erect on it, have unlimited light on three sides, while the subway cars and trains bring about ten thousand people an hour to their door.

THE Philadelphia Parkway Association, of which Mr. Albert Kelsey is the Secretary, has issued a very pretty and interesting pamphlet in aid of its scheme for cutting a wide parkway in a straight line from the City Hall, through Logan Square, to Fairmount Park. Architects who know Philadelphia do not need to be told of the comparative poverty of the city in dignified features; and the City Building itself, although one of the costliest and most magnificent municipal structures in the world, cannot be seen, as a whole, except from a point so close that its architectural effect is spoiled. It is estimated that the new parkway will not cost more than five million dollars, and this sum should easily be made up by the increased value of the land fronting upon it. Apart from this, however, a street of this kind through the middle of a city so closely and monotonously built up as Philadelphia would be a great public benefit. Beautiful and interesting as Fairmount Park is, it seems a long way off from the poorer quarter of the city, and a wide street through the middle of this portion, leading straight to the Park, planted with trees, and itself constituting a charming promenade, would be a great blessing to the people who now rarely, or never, see the Park.

ALTHOUGH, fortunately for the owners of twenty-story office-buildings, no general light and air easements are recognized in this country, there are circumstances in which the tenant of a building can legally prevent the light from being cut off from a window important to him. A case involving this principle was tried a few days ago in New York, where the tenant of an office in a large building on Forty-second Street sued for an injunction to restrain the owner of the building from making an extension of it which would cut off light from a window in the office in question. The court held that the contract of lease between the owner and the tenant implied that the latter should continue to enjoy, during the term of the lease, so far as any operations of the owner were concerned, the same amount of light and air that the premises received at the beginning of the lease; and that the owner could not rightfully diminish such light and air. An injunction was, therefore, issued against the owner, and he, and other owners in New York, will, henceforth, have to ask leave of their tenants before darkening their windows.

A RATHER extraordinary development in American economics is just now attracting the attention of the newspapers. Our readers know something of the proceedings of the window-glass trust, which, a few years ago, conceived the idea of shutting off competition by making friends with the glass-blowers' union, and supplying its officials, as is reported, with several hundred thousand dollars' worth of shares in the trust, with the understanding that the union would drive out of business all the independent window-glass factories, by refusing to allow union men to work in them. This contrivance was

Entered at the Post-Office at Boston as second-class matter

perfectly successful, and, within a few months after it was put in operation, every independent window-glass manufactory in the country had closed its doors. As usually happens in such cases, however, the trust soon found that the weapon which had proved so efficacious against its competitors had two edges; and the union began to try its hand at keeping to itself some of the advantages which it had so easily procured for its partner. The number of union members was restricted to about two-thirds the force requisite for operating the factories of the trust, so as to guard against the possibility of any member being left unemployed; and new members were admitted only under severe conditions, and on payment of an admission fee said to be five hundred dollars; while the output of glass by the trust was limited to a quantity prescribed by the union. Things have gone on in this way for two or three years, and, curiously enough, it is workingmen who have been the first to rebel, the Knights of Labor, of which the glass-blowers' union is an assembly in good standing, having officially prepared a petition to Congress to have window-glass, which now pays a duty of about one hundred per cent, put on the free list, for the reason that the duty prevents the adoption of improved methods of manufacture, unsettles business through arbitrary changes in prices at the dictation of the confederates, and makes the Government of the United States a partner with "this greedy monopoly of manufacturers and blowers, who are a detriment to the industry, and a curse to the country."

THE high-tariff orators have so often wept with joy over the beneficent results to the workingman of protective duties that this appeal of the most respectable and most powerful labor organization in the country to have the duty altogether removed from one of the most highly-protected manufactures will come upon them like a cold shower-bath. There is not the slightest probability that window-glass will be put upon the free-list for two years, at least, for the obvious reason that if the Knights of Labor were gratified by being enabled to buy English and Belgian window-glass at half the price that they now pay for it, they would soon be clamoring for the privilege of buying eggs and butter and meat and vegetables from the Provinces for half what they now pay, and clothing and blankets and shoes and leather and wool and a thousand other things, for prices approaching those for which the same things, often made in America, and exported, are sold abroad; and the system of high protection would begin to crumble away.

MR. CHARLES SOOYSMITH proposes to apply to the construction of the Pennsylvania Railroad tunnel under the Hudson River, which is now assured, the freezing-process already used in sinking mine shafts, by which soft earth around the excavation is frozen, so as to keep its place until the supporting lining can be put in. The soil under the Hudson River, opposite New York, is a fine silt, of great depth, and seems well adapted to treatment by freezing. In order to reach the silt with the chilled brine used for freezing, it will be necessary to drive a small "pilot tunnel" through the middle of the proposed excavation, in which the main pipes will be carried, distributing the brine around it by means of radiating-pipes.

MR. H. J. CAMBIE, of the Canadian Society of Civil Engineers, has made a curious and important observation upon clays. It appears that a portion of the Canadian Pacific Railway passes though a valley almost without rainfall, through the bottom of which flows the Thompson River. Above the river are high clay bluffs, forming the edge of a sort of table-land, some two hundred feet above the river. When irrigated, this clayey table-land is fertile, producing several crops of hay a year, and the farmers utilize it for that purpose, irrigating it with water from the river or its tributaries. Since irrigation of the land began, some forty years ago, there have been many land-slides. One of these, a few years ago, carried a tract of about a hundred acres directly across the river, forming a dam seventy-five feet high, and completely blocking its course; and another recently damaged the railway. In consequence of the latter, suit was brought by the railway company, to prevent the farmers from irrigating their fields, on the ground that the irrigation softened the clay subsoil, allowing the ground to slip. This view was confirmed by experiment, the experts, of whom Mr. Cambie was one, finding that while ordinary clay, in the moist condition in which it is usually found in the ground, will not absorb any more water, and is only superficially affected by washing, clay that has once been so completely dried as to lose its cohesive property absorbs water like a sponge until some sixty per cent of its weight has been added, when it falls into a liquid mud, nearly as fluid as water. Even when the clay has not become powdery by drying, but has taken the form of indurated lumps, it will still soak up water until converted into fluid mud. As the clay of these hayfields exists, to a great extent, in the form of such dry lumps, it seemed probable that copious irrigation through the season might liquefy it, so as to allow the ground over it to slide; while the objection that the clay on the immediate bank of the river was not affected appeared to be answered by the fact that this clay, being constantly kept moist by the water of the river, preserved its solidity.

A CONTRIBUTOR to the New York *Tribune* has sent long and rather attractive descriptions of what he calls the "municipal activities" of certain English cities, particularly in Yorkshire. He is evidently a partisan of collectivism of this sort, and the showing which he makes is tolerably good, although the fact that Sheffield, one of his model towns, "is barely beginning to receive substantial returns" from its "large investments in municipal undertakings," some of which have been five years in operation, suggests to the skeptical mind a suspicion that, when the bills for repairs and renewals, which, under ordinary circumstances, begin to be formidable soon after the fifth year, are all paid, the "substantial returns" may look a little less substantial. We have no desire to undervalue municipal enterprise in behalf of citizens, but it is notorious that the temptation to neglect renewals and repairs, for the sake of making a good financial showing, is too strong for most municipal managers to resist; and, as has already happened in at least one case, a "municipal activity" which showed gratifying returns from year to year may suddenly have to be abandoned, with most of the capital sunk in it, for the reason that the plant had been so neglected and abused, in the effort to show a good income over expenses, that, when it finally broke down, there was nothing worth saving in the whole equipment.

AN illustration of the British "reverence" for art is afforded by the recent discovery, in a "rockery" on an estate in Essex, of a piece of marble, or, rather, of two pieces, bearing a Greek inscription of the fifth century B. C., and another piece, sculptured, which turns out to be a missing portion of the Parthenon frieze, belonging to the group of horsemen in the Panathenaic procession. The inscribed slab of marble is known to belong to a monument set up in Athens in honor of the volunteers from Cleonæ who fought on the side of the Athenians in the battle of Tanagra against the Lacedæmonians and Eubœans, and is also known to have been brought to England about 1770. According to the accounts, it was picked up in Athens by Stuart, who was then engaged in writing his great book on the "*Antiquities of Athens*," and sent, with some other marble fragments, in charge of a sea-captain of his acquaintance, to Smyrna, where he expected to find it on his way home to England. When Stuart reached Smyrna, however, his marbles had disappeared, and it was not until after his arrival in England that he found them in the hands of a Mr. Jones, to whom they had been presented by a naval officer. The inscription was at that time copied and published, but Stuart seems never to have claimed his property. Meanwhile, a noted antiquary, Thomas Astle, is known to have been in the neighborhood, and is quite likely to have bought the old stones of Mr. Jones, and to have carried them off, for the rockery which they until recently adorned stands upon an estate which once belonged to him. We may surmise that, on the death of Astle, who, at least, knew something of the value of his marbles, his surviving relatives lost no time in clearing out the "old rubbish" which he had collected, and that anything so uninteresting as old Greek bas-reliefs or unintelligible inscriptions soon found their way to the ash-barrel, whence they seem to have been rescued by the gardener, in search of lumps of rock for sheltering ferns. Although the rains of a hundred and fifty years have ploughed "grooves" in the face of Phidias's aristocratic young horseman, the figure does not seem to be any worse off than the mangy wrecks which represent, in the British Museum, the rest of the frieze.

THE THIRTY-SIXTH ANNUAL CONVENTION OF THE AMERICAN INSTITUTE OF ARCHITECTS.[1]—II.

THE Committee on Foreign Correspondence reports steady increase of exchanges and correspondence.

The "*Proceedings*" and the "*Bulletin*" have been sent to forty-six foreign societies, to nineteen foreign periodicals and to fifty foreign correspondents. The book on gardens published under the auspices of the Institute was forwarded to forty foreign societies.

Societies in the principal cities of the world have been requested to send the Institute their building and municipal regulations, and replies have been received from London, Paris, Berlin, St. Petersburg, Buda-Pesth and Brussels. St. Petersburg has asked information about the course of study in our schools, and has received with thanks the information desired.

The Committee on Contracts and Lien Laws has, in conjunction with a committee appointed by the National Association of Builders, revised and published the uniform contract.

The joint Committee has endeavored to preserve as much as possible of the form in use for the past thirteen years, leaving out objectionable features, simplifying and adding some clauses. The most notable omission is that of the clause designating the architect as the agent of the owner.

Article II has been modified to clearly show the architect's ownership of the plans and specifications, and that the charges for the architect's services and use of plans are to be paid by the owner, thus condemning the unprofessional practice of making contractors pay for detail drawings.

The Arbitration Clause has been made more effective, to facilitate settlements out of court of disputes not adjustable by the architect.

The Committee had before it the form of contract approved by the Royal Institute of British Architects, a Washington form, and numerous forms from individual architects, and believes it has, under legal advice, provided a form to meet emergencies which deals justly with owner and contractor, which will admit of almost universal application and be used even more than the previous form. Of the latter were sold about 40,000 copies per year.

The Committee thinks that general adoption of this form of contract will give it a standing in the courts which no individual contract could possess.

The Committee to report on Reports of Special Committees submitted the following: —

The Committee on Conference with the Architectural League on Competition, Codes and Coöperation asks to be discharged, offering no suggestions except a general recommendation for some appropriate action to clear up doubtful clauses in the Code of Competitions.

The Committees on Legislation for Government Architecture and on Fine-Arts Commission and Bureau of Architecture simply report progress and state that, on account of conditions already existing, favorable in many points-of-view, they find it unadvisable to urge any decided changes at present.

The World's Congress Committee has no recommendations to act upon, in view of the postponement of the St. Louis Exposition.

As to the other Special Committees, appreciation of the work of each is noted; the aid of every member of the Institute in furthering the important work of the Municipal Improvement Committee is urged, and, finally, attention is called to the importance of matters before the Committee on Competitions and the supreme necessity, where competitions are necessary, for a clear statement of conditions, with competent advisers and with judges of the highest standard.

Following are excerpts, copies, or résumés, of the more generally interesting of these Special Committees' reports: —

The report of Mr. Alfred Stone, the delegate to the National Fire-protection Association and to the National Conference on Standard Electrical Rules, contained matter of interest. He had been appointed upon request of the Fire-protection Association that a representative of the American Institute of Architects attend its annual convention, and attended in that capacity a convention in Philadelphia in May last.

The membership of this Association is drawn from stock fire-insurance companies, and mainly from persons having charge of the improvement and inspection of risks. The objects are: "to promote the science and improve the methods of fire-protection, to obtain and circulate information on this subject and to cause coöperation in matters of common interest," but with no regard to insurance-rates.

Mr. Stone met with a cordial reception. There were discussed: "Danger of Fires in Breweries"; "Fireproof Construction"; "Uniformity of Construction"; "Protecting Coverings for Doors and Windows"; "Automatic Sprinklers," etc. Mr. Stone remarked that the architect's education and experience fit him to appreciate better than the insurance-companies the requirements in such special cases, and also that the companies have suffered largely from bad construction, for which the architect has been sometimes responsible, the owner often through unwillingness to pay the extra cost of fire-protection, for which until lately the insurance-companies have given him no allowance. He notes a great change already effected and a greater in prospect through coöperation of insurers and insured, and points out how the architect can advance this improvement by advocating better methods of construction and by inducing the companies to recognize these better methods and to make corresponding reductions of rates.

He recommends the Institute to continue its representation, as invited, at the conventions of the Association.

The delegate also attended the National Conference on Standard Electrical Rules, endorses the effort to establish a uniform code of rules for the country, such as now enforced in large cities with material gain in safety to life and property, and recommends that the Institute continue its representation at these conferences.

A resolution that the Board of Directors be authorized to appoint delegates in accordance with these recommendations was passed.

The committees on a Fine-Arts Commission and a Bureau of Architecture carefully discussed the subject of a "National Bureau of Architecture" and other fine-arts, and drew up various suggestions. At first they hoped to prepare a working-scheme for a commission or bureau that would ensure the execution of work in Washington on the lines prepared by the Park Commission. They hoped, too, that purchases of works of art by the Government might be made under expert advice, that the building work of the Government might either be put under one control, or that the different Departments might adopt methods as intelligent as those of the Treasury Department.

It was found, however, that the members of the Park Commission (who were well informed as to Washington affairs) felt that although the consummation of the scheme to place the work of the Government under the direction of a commission or bureau, created for the purpose was eminently desirable, yet it would be unwise to press this question upon Congress until after the work of the Park Commission had been submitted and passed upon by Congress and its value estimated. They thought it should be remembered that this Commission was created through the efforts of the Institute of Architects, and to propose the appointment of another Commission before the work of the first has been publicly justified would seem premature and unwise. They urged that with delay the proposition might be brought up with much better chance of success.

These opinions controlled the Committee. They were the more willing to remain inactive seeing that the number of buildings produced under the Treasury Act would soon be much greater and probably be standing argument for a general change; and, besides, they saw other Departments, like those of Agriculture and War and the District of Columbia, adopting methods similar to or, perhaps, better than those in use by the Treasury Department.

The attitude of the Government towards artistic work has been constantly and rapidly improving. The question seems to be whether when the disposition towards art is in such an improving condition it is well to be contented or to strive for still better things during these favoring conditions. Until now the Committee, following to a great degree the urgent advice of the Park Commission, have thought it wiser to delay action.

The Report of the Committee on Competitions, an interesting one, reads as follows: —

"There have been no stated meetings of the Committee during the year. The Code which resulted from our first report was an experimental one and there is evidence that it has already had a beneficial effect on the conduct of competitions. Those who draughted the Code thought it undesirable to state that certain forms of competition were disapproved and considered it sufficient to name the existing forms and point out what results were desirable and how best obtained.

"In one instance, at least, the attitude of the framers was misunderstood, and it was claimed that a competition where certain competitors were paid one price, certain others another price, and others again paid nothing, for rendering the same service, was a form of competition approved by the American Institute of Architects. If the Code was generally understood to have this meaning the Committee suggest that it be modified, or some explanation appended. The new duties of the Committee have not been exercised to any great extent. The Committee has stood ready to advise when requested, but have not thought it incumbent upon them to offer advice unasked, or to interfere when unsatisfactory conditions of a competition have been brought to their attention by others than those directly interested.

"The operations of customs and public opinion are steadily trending towards a clearer understanding of the interests that are served by a competition, and the best way of reaching results. The public, as well as the profession, are beginning to appreciate the importance of the jury; and the more undesirable forms of competition are being gradually eliminated.

"When all is said there is one supremely important condition in any competition which far outweighs any consideration of the number of those who compete, or the payment to the competitors, and that is the employment of professional service both for the programme and for the award. No competition may rightly be called improper if it is fairly stated and fairly judged. The best man will compete under the Tarsney Act, although there is no compensation; first-rate men entered the competition for the Washington Hospital. In both cases the assurance of fair play was the sole operative factor.

"In view of this fact it is evident that a great responsibility rests on any architect who is asked to serve as expert either in drawing up or judging a competition. With him, to a large extent, rests the

[1] Continued from No. 1408, page 93.

future of competitions. Even the most careful man acting in this capacity is apt to be betrayed by his committee.

"Our attention has been called to the result of a competition recently held for the Foundry Methodist Episcopal Church in Washington. The Committee pledged themselves not to open the envelopes containing the names of the competitors until a final selection was made — which final selection was to be made by the Quarterly Conference on the report of the Committee and its adviser.

"One of the envelopes was opened by the Committee before the decision of the Conference, and the Committee had a consultation with the architect, whose plans were modified in essentials and then accepted by the Conference. Their professional adviser, Mr. James Knox Taylor, was not consulted in this action, and it is greatly to be regretted that a competition, in which the chief security for justice lay in the acknowledged position of the professional adviser, should have been decided in direct violation of the terms of the programme, to the injury of the other competitors and of the professional adviser, who was unwittingly involved in this scandal.

"The Committee wish to reiterate what is, indeed, the publicly expressed opinion of the Institute, that the best results are obtained without competition, but that where competitions are necessary, good advice in the programme and fair judging and award by competent experts are the most important features. Finally, that the limited properly paid competition is the properest form, producing the best results for the owner and encouraging the self-respect of the architect. To be asked to compete on such conditions is an honor; to be asked to compete on other terms is not an honor, but a request for a favor.[1]

"The method of selecting the architects to compete for the Liverpool Cathedral opens up a new phase of the matter which has possibilities. The authorities in their general circulars ask any man who has done church work which he considers worthy to send them photographs or drawings of such work, and the Committee, from the actual performance, will select the competitors. From this position it is but a step to select an architect in the same way; in other words, to let the competitors submit for judgment, not studies for the proposed building, but drawings or photographs of similar work which they have done, with such evidence as they wish or the Committee desire as to their ability, and have the competition decided on the ground of past performance — which is, after all, a better guaranty to the client than a clever plan or a happy solution of a problem.

"In closing, the Committee would urge that every member use his influence to discourage competitions where they are not essential, and to see that programmes are carefully drawn up and the work fairly judged, where competitions are necessary. But above all, that they should exercise the greatest care and discretion when acting as professional adviser."

The Committee on Municipal Improvement reports a paper prepared by the Chairman for the American Park and Out-door Association on "The Relation of the A. I. A. to Municipal Improvement," in general drawing particular attention to the part of the Institute in the appointment of the Washington Commission and to the admirable work of that Commission. This paper was read by Mr. Albert Kelsey at the meeting of the Association held in Boston in August, from which meeting resulted a Committee on Federation of many societies of kindred aims, on which the Chairman (Municipal Improvement Committee A. I. A.) has been invited to represent the Institute. The Committee stands ready to give advice in specific cases to any local body. The Committee is in receipt of numerous reports from correspondents showing a great general interest in municipal improvement and describing the progress of the movement in several cities. An abstract of these reports will be printed in the "*Proceedings*."

During the afternoon session of Thursday the Convention heard papers on "The Improvement of Washington" (illustrated with lantern-slides) by Daniel H. Burnham, Frederic Law Olmsted, Jr., and Charles Moore.

The latter is printed with this account of the doings of the Convention.

The Evening Session of Thursday was held at the Library of Congress, where the members met at 8.30 o'clock to examine and have explained to them the drawings and models submitted to the Senate Committee on the District of Columbia by the "Park Commission," D. H. Burnham, C. F. McKim, Augustus St. Gaudens, and Frederic Law Olmsted, Jr.

The Morning Session of Friday, Dec. 12, Second Vice-President Alfred Stone in the Chair, opened with the reading of a paper by Captain J. S. Sewell, Corps of Engineers, U. S. A.

Then followed some discussion of matters kindred to the subject of this paper, the Chairman remarking that Boston has a standardized specification such as Captain Sewell recommended, and Mr. Andrews following with an interesting account of the coöperation of architects and engineers in the planning of Boston schoolhouses. A paper by Mr. Smithmeyer on "The Evolution of Design" was read. Mr. Gilbert offered the following tribute to the memory of Walter Cope: —

"In the recent sudden death of Walter Cope, this Institute has lost one of its most distinguished and valuable members. Mr. Cope was born in the year 1860 and had therefore reached only his forty-second year. Yet in spite of the comparatively few years that he had been in active practice, the firm of Cope & Stewardson had produced many buildings of the highest interest.

"Commencing their more important and characteristic work with Denbigh Hall at Bryn Mawr College at a time when John Stewardson was still alive, the firm has executed at Bryn Mawr, at Princeton, at the University of Pennsylvania, and at Washington University, St. Louis, a series of collegiate buildings of a beauty and appropriateness that have fixed the attention and aroused the enthusiasm not only of architects and educators, but of the general public. Adopting a type of later English Gothic or Jacobean and modifying it to meet the requirements of local materials and of modern methods of instruction, Mr. Cope (who, after the death of John Stewardson, was, in all artistic matters, the unquestioned head of the firm) gave to his collegiate buildings an expression of eminent fitness to their uses, while still markedly insisting upon the continuity of our architectural traditions.

"It was, however, not alone in college work, but in buildings of the utmost diversity of purpose, that his talents were manifested. Judged by the standard which Matthew Arnold holds as the true test of artistic and literary performance, excellence sustained at a high level through a great volume of work, Walter Cope's buildings must be regarded as having reached the foremost rank of contemporary architectural achievement.

"In maintaining the standards of professional conduct established by the Institute, Mr. Cope was unswerving and inflexible. Upon his companions the impressions left by his work are of his constant sincerity, his spontaneity and truthfulness, his joy in art, his splendid scorn of wrong."

A resolution was offered by Mr. R. S. Peabody in respectful memory of the late Senator MacMillan.

Resolved: That by the death of Senator MacMillan our art has lost an active and appreciative advocate. For his broad-minded interest and intelligent coöperation with architects and artists in their efforts to beautify Washington our profession and the country will long remain his debtor.

The matter of the admission to the Institute without examination of graduates of architectural schools was brought up. Professor Warren expressed his opinion that "special course" students should be examined before admission, but that holders of a degree in architecture from schools, having a four years' course, which are departments of architecture in chartered institutions of learning should be admitted without examination.

It was decided that a list of schools be prepared.

An amendment admitting holders of degrees from foreign institutions was referred back.

Mr. Gilbert reported fund of $15,000 raised toward payment for the Octagon House, from subscriptions of members present at the Convention.

In the Afternoon Session of Friday papers were read as follows: W. B. Las Casas on "Organization for Municipal Improvements," Albert Kelsey on "The Modern City," Owen Fleming on "Improvements in London."

These papers were illustrated with lantern-slides and were all of great interest. Mr. Fleming's paper on "London," which was read for him, will be published later. Mr. Owen Fleming is Secretary of the Architectural Board of the Council of London in charge of improvements.

In the Morning Session of Saturday, December 13, Second Vice-President Stone in the chair, much unfinished business was satisfactorily despatched. The members had previously, by invitation of the President of the United States, met at the White House and were conducted over the building and shown the work of remodelling which has been done by Mr. McKim.

On meeting in the Convention-room a paper was heard from Captain Sigsbee, U. S. N., on a project of his for permanent marble review-stands in Lafayette Square.

Mr. Marshall, of the New York Chapter, brought up the question of an architect being called upon to give bond to fully discharge his duties and to guarantee his construction and limit of cost, which proposition the New York Chapter desires to reject.

Some miscellaneous business before the Convention being disposed of, the Convention adjourned at the end of the morning hour with the casting of ballots and announcement of officers elected and the place of meeting for the next Convention.

Ballots for election of officers resulted as follows: *President*, Charles F. McKim; *First Vice-President*, Frank Miles Day; *Second Vice-President*, Alfred Stone; *Secretary and Treasurer*, Glenn Brown; *Board of Directors*, Robert S. Peabody, William B. Mundie, Isaac C. Ditmars; *Auditing Committee*, S. A. Treat, Wm. G. Preston.

The following were elected: *Fellows of the Institute*, W. R. Mead,

[1] The Committee had some correspondence in connection with the McKinley Memorial at Philadelphia and took the following stand in regard to the jury, the quotations being from personal letters from members of the Committee: "The experts should be decided upon and named in the programme. The character of these gentlemen will, in many cases, induce men to enter the competition or to refrain from doing so."

"It seems to me in every way desirable that the jury should be selected and named in the programme. For such a competition, especially where the jury are to have the assistance of another committee, three seem to me better than five, and as a mere suggestion I would say they should be, one a sculptor, one an architect familiar with monumental work, and one a landscape-architect or an architect familiar with landscape work."

an eight-horsepower motor, which gives normally 2,000 revolutions a minute. The motor is well covered, so as to prevent all penetration of water, and a continuous current of 525 volts can be applied. Above are two bobbins: On one is wound the wire upon which the current is received, the extremity being exposed in such a manner as to allow connection with a hook suspended from the tram or electric-light wire; on the other bobbin is wound the return wire, the free end being connected with a cast-iron block to be fastened to one of the tramway-rails. There is beneath the covering a compartment containing two circuit-breakers, a circuit-closer, and a commutator. To start the apparatus, it is only necessary, after connecting the two wires to the line giving the energy, to close the circuit and start it running slowly with the rheostatic guide; the guide being fastened to the circuit-breaker the motor runs normally. The time necessary for starting is about a minute. The bobbins on which are wound the conductors can receive 200 metres (656.167 feet) of insulated wire; if to this are added the 200 metres of hose on the reel and the thirty-five metres (114.83 feet) to which the water can be thrown, it is seen that a distance of 435 metres (1,427.16 feet) can be covered. The distance that the water can be thrown, nearly 115 feet, is accomplished with an orifice of 18 millimetres (.7 inch), and a volume of 350 litres (92.46 gallons) a minute. The whole machine can be placed on a hand-cart or on a little two-wheeled wagon drawn by one horse. Its total weight, with accessories and two men on the seat, is about 1,040 kilogrammes (2,292.78 pounds). The motor and pump are not longer than a metre (39.37 inches) and about one-half a metre (19.685 inches) wide and one-half a metre high. Behind the machine is a reel capable of holding 300 metres (984.25 feet) of hose, two lances, a ladder with hooks, an axe, a hydrant-key, a nozzle, etc. The weight of this reel, equipped, is 330 kilogrammes (727.518 pounds). The idea of this pump, which is the only one of its kind in France, if not in the world, was suggested to M. Robert Lefebvre, the captain of the Rouen Fire Company, by a conversation he had last year with a German engineer at the Berlin Fire Extinguishing Exposition. This latter had conceived the idea of an electric-pump for cleaning the walls of buildings, etc. If sand thrown by an electric-pump could clean buildings, why could not water thrown in the same manner extinguish fire? In the solution of this question, the electric fire-pump was born." — *N. Y. Evening Post.*

Sewage-disposal at Pittsfield, Mass. — About two years ago the authorities of Pittsfield, Mass., decided that some more advantageous method of disposing of the sewage than allowing it flow into the Housatonic River was necessary, and active measures were taken to install a more hygienic system. The sewage is now pumped a distance of two miles and a half from the outskirts of the city to large filter-beds, where it trickles through the filtering-material, consisting of sand, to underdrains, and thus is discharged, clarified, into the river. The pumping-station, by means of which the operation is performed, is believed to be the first electrically driven pumping-station for sewage-disposal in this country. According to the *Electrical World and Engineer*, the pump is especially designed for this class of work. The valves are of the clapper type, leather-seated and are free from any possibility of becoming clogged. The pump is triple-acting, and has a capacity of 2,000,000 gallons in ten hours, delivering at a pressure of seventeen pounds per square inch, the lift to the filter-beds being about 54 feet. The pumping-plant is operated only during the daytime, and to provide for the disposal of sewage during the time it is not in operation large storage reservoirs of some 1,500,000 gallons' capacity have been built underground between the pumping-station and the screen-house in the rear. These reservoirs are three in number, and are roofed with brick arches. To prevent any offensive odor from escaping from the reservoir, ducts are provided for carrying all gases, etc., to the base of the chimney on the power-station. Should the draught of this chimney be insufficient to carry off such vapors as may arise, a rotary-fan has been placed at the base of the chimney to assist in the ventilation. This fan is not yet in operation, but as it is to work both day and night, and as the circuit to the pumping-station is cut off at the central lighting-station when the pumps are not in operation, it is probable that a water-motor will be used for running the fan. A complete system of hot-water heating, with radiators, has been installed. — *Fire and Water.*

The Use of Petroleum in making Pig-iron. — Two Russian engineers, named Pitersky and Ivanoff, have devised a process by which petroleum can be utilized in the production of pig-iron in connection with a certain quantity of solid fuel. In a paper read before the Baku Technical Society, the following description of the process was given: The solid fuel is placed in a special generator, into the lower part of which are introduced the heated gases from the combustion of petroleum. The fuel, charged from above, gradually falls to the bottom and becomes heated; dry distillation results, and the gaseous products are drawn off from the upper part of the generator and utilized for fuel, while the resulting coke continues to descend. The products of combustion entering the lower part of the generator pass over the incandescent coke, are deoxidized, and are thus available as reducing agents, which can afterward be used in the second furnace. This furnace, which is used for producing iron, resembles an ordinary blast-furnace, from which it merely differs in having a tube running down the centre. The ore and fluxes are placed in the circular space between the walls of the furnace and the central tube, the latter being charged with a quantity of coal sufficient to supply the iron with the required equivalent of carbon for converting it into pig-iron, also, if necessary, with fluxes for changing the composition of the slags. The circular space and the central tube are provided with covers to retain the gases. The heated reducing gases from furnace No. 1 are made to enter the lower part of furnace No. 2 through several openings. The gases at first melt the ore and slag. In ascending, without changing their composition, they convey their heat to the materials, and they begin to act chemically, by reducing the iron-oxides, absorbing their oxygen, and becoming converted into carbonic-acid. Although the gaseous medium gradually acquires pronounced acid properties, the effect of the carbonic-acid is counteracted by the fall in the temperature. The spent gases collecting in the upper part of the furnace are utilized as fuel, the reduction process being preferably carried out by means of carbonic-oxide. The central tube terminates at the place where a temperature of 900 degrees Cent. prevails. The atmospheric medium at this horizon being of a reduced nature, the carbon dropping into the charge could only be utilized in combining with the iron to form pig-iron. The pig-iron and slags produced are tapped in the usual manner. The molten pig-iron from furnace No. 2 is run into the Bessemer converter. The pig-iron is converted into steel; the gases are led into generator No. 1 and serve for producing pig-iron in furnace No. 2. — *Iron Age.*

Jokes in Bricks and Brass. — In the year 1679 the Danes made a descent on Hamburg, then, as now, the great seaport of the German Confederacy. But the good people of Hamburg had had warning of the contemplated attack. They were ready, and the Danish soldiers met with so hot a reception that they were only too glad to take a hurried departure, leaving many of their number dead and dying behind them as a result of the conflict. The Hamburgers struck a coin to commemorate the event, and one of these coins has lately been sold among a collection which belonged to a deceased collector in Berlin. On one side are these words: "The King of Denmark has been to Hamburg. If thou wouldst know what he achieved, look on the other side." You turn the coin over, and the other side is — a blank! There are more than one of these historic jokes to be seen in various parts of the world. A notable one is a monument in the market-place at Coblentz. When Napoleon's conquering army marched through this city on its way to crush Russia, a French general erected this monument to celebrate this victorious progress, and on it carved an inscription setting forth the fact that Coblentz had been added to the French Empire, and signed with his own name. A few months later and a Russian general entered the town, but in pursuit of broken regiments of starving Frenchmen. He saw the monument and read the grand inscription. He did not blot it out, but, with grim irony, he carved beneath it, "Seen and approved by me," and he added his name. So the words remain to this day. There is a curious old almshouse in the Herefordshire town of Leominster. On the outside wall is a rude carving of a man armed with a heavy hatchet. Underneath are these words: "He who gives away all before he is dead, let him take up this hatchet and chop off his head." A former inhabitant of the town was the builder of these almshouses, and so charitable was he that at the age of about sixty he found himself penniless. He ended his days in the very almshouse he himself had built, and before he died requested that this amusing warning might be inscribed for the benefit of posterity. — *Answers.*

Bamboo. — The increasing importation of bamboo seems to indicate that Americans are beginning to appreciate the exceeding utility of that remarkable plant. In the Orient it fills so large a place that it may be compared with iron and steel in the Occident. When dried and cut into slivers it makes nails which never rust. These bamboo nails have recently appeared in a Broadway shop as souvenirs. When a portion of its surface is removed, steamed or heated in a fire, it becomes pliable, and may be bent into various angles. These two properties enable the Eastern cabinet-maker to manufacture it into stools, chairs, tables, screens, étagères, trunks and armoires. In the United States bamboo and rattan are made into ornamental furniture on a small and delicate scale, but the use of the large-sized bamboo for massive and durable furniture has not yet been attempted. Builders in the cities on the eastern coast of Asia use the bamboo for masts, poles, ladders, step-ladders, scaffoldings, painters' stagings, and other purposes where both strength and rigidity are demanded. With equal weights, bamboo is five times as strong as wood, and with equal strength is but one-third as heavy. The joints in the stems enable a workman to lash two poles together without any possibility of slipping, which is not the case with ordinary timber poles. This does away with the necessity of nails, and so increases the life of scaffoldings indefinitely. Every bamboo is practically a series of air-chambers. A boat-hook whose shaft is one of these stems is a life-preserver which will support one or two persons; while a bamboo gaff or boom will keep a dozen persons afloat. In household furnishing and decorations the Eastern reed offers unlimited variety. Thus far it has been employed in this country for picture-frames, easels, fancy chairs, and curtain-poles. In the Orient the larger sizes, which range from 3 to 12 inches in diameter, are sawed into various lengths and used for card-receivers, sugar-bowls, cigar-boxes, hand-trays, spoon-holders, umbrella-stands, drinking-utensils and jewelry-boxes. The larger ones are cut through and sawed with scroll-saws into various patterns, which are utilized as jardinières or the holders of pewter boxes, incense-cases and mantel-ornaments. When softened by hot water and split into thin strips these can be woven with cord into veranda and window shades, door-mats, and hall-mattings. When split still finer the strips can be braided into table-mats, chair seats and backs, dado wall-covers and a floor-covering which is almost indestructible. — *N. Y. Evening Post.*

Waterfall near Chihuahua, Mexico. — William P. Dunham, a prominent Denver mining-man, has returned from Mexico recently. In addition to a tale of the vast mineral wealth of the Mexico district, Mr. Dunham also has a story of a wonderful waterfall, which probably enjoys the distinction of being the highest waterfall in the world. The fall is known by the Indian name of Basaseachic, and is located about 190 miles west of the city of Chihuahua, near the summit of the Sierra Madre Mountains. The elevation of the mountain is 6,500 feet above sea-level. The cascade falls 978 feet. — *N. Y. Tribune.*

S. J. Parkhill & Co., Printers, Boston, U. S. A.

of marked unity of style. The Argive school of sculpture, from which came Miron, Phidias and Polycletus, pupils of one master, Agelidas, was the nursery of the Attic. Dr. Waldstein, with that skill in comparative study that distinguishes him, has collated these remains with the recognized works of Polycletus, discovering in them personal characteristics which mark them all as the work of a single school, if not of a single hand, which he holds to be the hand of Polycletus himself. He finds it necessary to revise the current estimate of Polycletus, and even his own, being convinced that this sculptor was "the most purely Classic artist of antiquity," and adding: "Polycletus is the sculptor of beauty, as Phidias is sculptor of sublimity, Praxiteles of grace and pure Greek sentiment, and the Bergamenians and Rhodians of action." The whole of Dr. Waldstein's essay is an interesting lesson to those who would know what the comparative study of art means.

In mechanical execution the book is of the best, a handsome folio, not intolerably big. The illustrations are not only technically excellent, but full of charm. Photogravures show well the delicate beauty of the sculptures: admirable half-tones set forth the views, the pictures of the lesser finds, and the skilful drawings in which Mr. Tilton embodies his courageous restorations. — *W. P. P. L. in the Boston Transcript.*

BOOKS AND PAPERS

THE D. Van Nostrand Company publishes in this country a translation of Paul Charpentier's book on timber,[1] which will find a welcome among the multitude of persons in this country who have begun to interest themselves in the production and use of timber. M. Charpentier begins at the beginning with his work, furnishing, after a botanical survey of the subject, some excellent chapters on sylviculture, clearing and replanting, and the exploitation of forests, followed by others on the allied subjects of the drying, seasoning and preservation of timber, and its protection from insects and diseases. To these are added some valuable chapters on the accessory products of forest exploitation, and methods of staining wood, and of utilizing timber wastes. As may be supposed, the book does not pretend to be a treatise on carpentry, or even on the strength of timber, but takes up wood as a substance, showing how it grows; what are its different varieties, their properties and the places where they are found; the methods of converting the different species into useful products, and the purposes to which these products are applied. Nothing just like this has, so far as we know, been done in English for many years; and scientific forestry, as well as the scientific utilization of timber, is so recent a study, that the ancient text-books are of very little use. It would be too much to say that M. Charpentier's work is everything that the American student can desire. Too little is said about American timber trees, and what is said about European timber is not always perfectly clear, as where we are informed that, out of a total annual consumption of twelve million cubic metres of Norwegian timber, ten million cubic metres are used for "household requirements and cultivation of land," and only a million and a half for firewood and building purposes; but it is, at least, comprehensive and most modern, and its defects can easily be overlooked for the sake of its merits. It is due to the translator, also, to say that much of the value of the book in its English form is due to the skill and care with which he has done his work. A more difficult treatise to translate well it would not be easy to find, but Mr. Kennell has accomplished his task with great intelligence, and with a smoothness which is gratifying to the reader.

WHAT Professor Carpenter's book on the heating and ventilation of buildings[2] should have passed through four editions in seven years is sufficient evidence of its value, and the fourth edition, which has been in great part rewritten, and increased in size about one-third, is more valuable than ever. The chapters which are entirely new relate to the mechanical systems of heating and ventilation which are now so justly in favor; to fans and blowers, and to school-house heating and ventilation; and these will be found particularly valuable to architects, whose most serious problems of the kind most often present themselves in connection with the heating and ventilation of school-houses by means of fans. A few years ago, the architect could shift all the responsibility for the designing of such an apparatus on the contractor, but that time has gone by, and the architect of a large school-house or public building, even if he relies upon a contractor, or a consulting expert, for details, must know approximately the sizes of pipe and ducts that will be needed, the extent and position of radiating surfaces, the dimensions of the boiler, and the necessary size of the chimney; and he is expected also to be able to give advice as to the kind of boiler to be used; to know when steam or grease traps will be necessary, and where they should be placed; to understand the relative advantages and disadvantages of horizontal and vertical engines, and to judge where inlet and outlet registers should be placed, and how much, if any, direct radiation should be introduced for night-work. If he is ignorant of these matters, his building cannot be economically and conveniently designed; and it is not too much to require of an architect at least sufficient knowledge to enable him to plan his building in such a way that it will not have to be altered subsequently to get in the necessary apparatus. As a resource in matters of this kind Professor Carpenter's book can hardly be too highly praised. The rules and tables which it gives for ascertaining the sizes of pipes, conduits and flues, radiators and registers, are not only reliable, but easily understood and applied, and invaluable descriptions are given of nearly all the recent devices, in the shape of improved boilers, temperature-regulators, fans and blowers, and electrical heating-apparatus, which the architect is likely to meet with, and in regard to which it is peculiarly necessary that he should be able to refer to the judgment of an expert, instead of depending upon the reckless and ignorant laudation, if not monstrous misrepresentation, which the travelling agents of the patentee often see fit to offer him. As every architect knows, the business of heating and ventilation is infested with the loquacious vendors of patent grate-bars, by the use of which sixteen pounds of water can be evaporated by burning one pound of coal; of powerful ventilators, consisting of a three-quarter-inch pipe, with one end inserted in the kitchen range, which will keep the atmosphere of a house as fresh and balmy as a June morning; of infallible grease-extractors, smoke-consumers and other devices, recommended by an imposing list of patrons, whose names are, in some cases, either forged or fictitious, but in regard to the merits of which the architect is often unable to judge accurately for himself. Where Professor Carpenter's book does not treat specifically of the appliance in regard to which information is sought, he generally gives principles which will enable an intelligent architect to form an opinion for himself in accordance with which he can conscientiously advise his client, and the latter, who expects the architect to know all about such matters, is always pleased to find that he was not mistaken in his anticipations.

NOTES AND CLIPPINGS

ELECTRIC FIRE-PUMP IN ROUEN. — Thornwell Haynes, United States Consul at Rouen, gives the following description of an electrical fire-pump used in that city: "It is composed of a centrifugal-pump, and

In the scheme for the development of the Mall, the plans contemplate along B Street, North, and B Street, South, a series of white marble buildings to be devoted to the scientific purposes of the Government, including the museums most frequented by vis tors to the capital. Such buildings so placed would give great dignity as well as continuity to the approach reciprocally to the Capitol and to the White House. Under the provisions of an Act of Congress, plans have been prepared by Messrs. Lord & Hewlett for a new Agricultural Department building, and the appropriation for the structure is confidently expected at the present session. The competition was conducted with the assistance of the Park Commission, and if the building shall be erected as planned, a pace will be set for the series on the south side of the Mall. Congress has provided also for plans for a new building to relieve the overcrowded National Museum, and these plans are now being prepared by Messrs. Hornblower & Marshall. Unfortunately, it is now contemplated that this building shall be of brick and terra-cotta. In case this idea shall prevail, the series on the northern side of the Mall (where the new building is to stand) will begin with a serious handicap. The problem now is to make it apparent to Congress that a great and important museum-building should have a character of its own in keeping with the treasures displayed within its walls and worthy of the Government it represents. Those who have immediate charge of the work are fully alive to the situation.

As is well known, the Commission's plans contemplate the purchase of the squares south of Pennsylvania Avenue from the Treasury to the Capitol, and the erection thereon of public or quasi-public buildings, among them a municipal building for the District of Columbia. The ideal location for the District-building is the site now occupied by Centre Market; but the importunate condition of the District in respect to a public building was such as to lead Congress to order the purchase of the square between Thirteen-and-a-half and Fourteenth Streets, and the competitive plans for the new structure will be exhibited to the members of the Institute at this meeting. Thus, while a departure is made from the exact site, the adherence to the general scheme is most gratifying.

In this connection it is worthy of record that the Daughters of the American Revolution, moved by a desire to aid in the park improvements and actuated also by a sense of future advantage to their own cause, have purchased as a site for their Continental Hall, Square 173, the second square south of the Corcoran Gallery of Art. This location, facing the White Lot, is certain to become a most desirable site for a semi-public building. It is to be hoped that other societies will acquire the two lots remaining, and that due regard will be had for architectural effect, so as to secure harmony among the buildings framing this portion of the park system.

An important, even an essential, feature of the park plan is the reclamation of the flats of the Anacostia, or eastern branch of the Potomac River, a project divided as to its cost. The improvement of the lower stretch of the river belongs to the National Government proper; and the Army engineers have long had plans for dredging the stream and depositing the soil behind channel-walls of stone. The recent River and Harbor Act carries an initial appropriation of $150,000 for this portion of the work, and contracts are now in process of award. Along the upper stretches of the river the improvement is a District of Columbia matter. The Commission recommended as at once the least expensive and the most effective treatment the creation of a water-park, the waters being held back by a dam and islands being created by dredging, as the topography permits. Until the titles to the property to be submerged and otherwise used shall have been established it will not be possible to go on with this portion of the plan.

Congress, however, has already taken steps to have the question of titles settled; and such is the urgent nature of the improvement from a sanitary standpoint that it cannot long be delayed.

The Senate Committee on the District of Columbia in its report calls attention to the fact that the plans of the Park Commission were the resultant of two coincident movements; one, technical in character, being the action of the American Institute of Architects at its annual meeting two years ago; the other a popular movement for the embellishment of the national capital, set on foot at the time of the celebration of the one hundredth anniversary of the removal of the seat of government to the District of Columbia. Among the objects proposed at that celebration was the restoration of the White House as the residence of the President of the United States, a project the imperative nature of which was already recognized by Congress. By reason of a most fortunate chain of circumstances a President alive to the importance of having the work done in the most thorough and artistic manner came to be entrusted with the task. It is in no way invidious to say that if the selection of an architect for this delicate undertaking had been left to this body the choice would have been the man whom President Roosevelt did select — the President of the Institute of American Architects. How well he has carried out the work, with what thorough respect for the traditions of the house, with what comprehensive knowledge of the universal language of his profession, with what noble self-restraint he has subordinated decoration to architecture, and with what modesty he has made the old mansion speak its own speech and not that of an individual architect — all these things you may see for yourselves.

The importance of the work on the White House by way of teaching the highest lessons of dignity, restraint and historic tradition, coming, as it does, at the very beginning of what we fondly hope is a new era in Washington, cannot be overestimated. To link the age that is past with the age that is waiting before has been the constant endeavor of the Park Commission; and the restoration of the White House affords a supreme example of such continuity.

Thus briefly and imperfectly I have sketched for your encouragement the progress of plans as yet scarcely a year old. In this connection I cannot forbear to advert to the fact that the one man in Congress with whom the work of restoring the L'Enfant plan and carrying it to its ultimate conclusion through the plans of the Park Commission was a passion has passed from the scene of endeavor. Suddenly, unexpectedly, at the moment of highest usefulness and promise, and just as he was beginning to see the fulfilment of plans and purposes pursued through thirteen years of strenuous and intelligent effort, Senator MacMillan's career on earth was terminated. It had been his expectation to press upon the attention of Congress at this session a combination of all the scattered authorities over District parks and reservations, and to create a single body capable of employing experts to perfect the details and to carry out thoroughly and vigorously the comprehensive scheme of the Park Commission. That task now devolves upon others; and it should be the duty of the members of the American Institute of Architects to exert their constant and determined influence towards the creation of such a board of control. By so doing they will complete a task to which they have already set their hands and, as I believe, their hearts also.

THE ARGIVE HERÆUM.

THE excavation of the Heræum of Argos for the American Institute of Archæology and the American School at Athens under Dr. Waldstein, whose eminent services to classical archæology are known to a great part of the readers of the *Transcript*, is the most considerable exploration of its kind that our countrymen have accomplished, and only next in value to the work done at Olympia by the German Government and at Delphi by the French School. It is a special cause for congratulation, because in this country such work gets no help from public funds, and must be carried through with self-denying effort by institutions whose means are small, and by private subscription. The first volume of the report has just been published by Houghton, Mifflin & Co., introduced by Dr. Waldstein's general sketch of the excavations, and containing detailed notices of the work of the American expedition in its several departments.

What makes Olympia, Delphi and the Argive Heræum interesting to study more than other places in Greece is that Greek art as much as Gothic centred in worship. All the arts, architectural, plastic and decorative, were lavished on temples and shrines. The fact that the Heræum was held for 2,000 years in paramount sanctity attracted to it a great accumulation of offerings such as in classical Greece and later in Christendom made the wealth and splendor of favorite shrines. In after centuries it was forgotten and its identity lost. In 1831 the site was first rediscovered by an English officer, General Gordon, who verified it by tentative excavation. More than twenty years later the Greek scholar and poet Rangabé made some further examination, imperfect, and soon given up for want of funds.

It was not till 1892 that, under the direction of Dr. Waldstein, excavation was undertaken there by American archæologists with the thoroughness and orderly method of modern scholarship. The volume now published contains, besides Dr. Waldstein's interesting notice of these excavations, a detailed account of the architecture of the Heræum by Mr. Edward L. Wilson, of its sculpture by Dr. Waldstein, its inscriptions by Mr. R. B. Robinson and Professor Wheeler, and a sketch of the geology of the plain and hills of Argolis by Dr. H. S. Washington. Vases, bronzes, and some other important subjects are left to be discussed in the second volume.

The commanding situation of the Heræum on a height at the head of the plain of Argolis made it a midway station for the three great Argive cities, Tiryns, Mycenæ and Argos. It survived them all, maintaining its religious preëminence for 2,000 years, down to the end of the classic period. Though every part of this long life has left its memorials, the finds are unequally distributed in time. Of the smaller objects found almost all are of early date. Terra-cottas, vases, bronzes, gems, and the like present the primitive styles in a multitude of examples; but of the classic period there are very few. Yet the primitive objects found here, the vases especially, have a bearing on some important questions of the history of art that gives them peculiar interest. Dr. Waldstein believes that the publication of them will make it necessary to revise in some respects the classification of ancient vases.

In architecture, though there is a continuous series of remains coming down from the oldest temple, to which our explorers are inclined to assign the very early date of the nineteenth century B. C., and which was buried in 423 B. C., the building of which the most important and significant remains survive is the second temple. This was built immediately after the destruction of the first, in the high summer of Grecian art, dating, it is believed, between the Parthenon and the Erectheum. So of the sculpture, substantially all of which belonged to this temple, a great many fragments have been recovered. There are no whole statues, but many beautiful heads, several in singularly good preservation, some admirable torsos, one or two nearly complete figures from metopes, and a great number of smaller pieces, all of the best period, of exquisite workmanship, and

G. L. Heins, J. L. Mauran, Elmer Grey, Ralph Adams Cram; *Honorary Members:* Samuel A. B. Abbott, of Boston; Andrew Carnegie, of Pittsburgh; Emil Vaudremer, of Paris. *Corresponding Members:* George R. Shaw, of Boston; John Jas. Burnett, of Glasgow; Bannister F. Fletcher, of London; Mervin McCartney, of London; Leonard Stokes, of London; A. H. Bloomfield, of London, and Wm. M. R. French, of Chicago.

The city of Cleveland was chosen for the next Convention.

THE IMPROVEMENT OF WASHINGTON.[1]

A LITTLE less than a year ago, one of the most brilliant and most successful members of the American Institute of Architects came to Washington to see the models and drawings prepared under the direction of the Park Commission. He was on his way to Italy for needed rest, and also for study that would be helpful in his profession. At the time of his visit, the exhibition was being made ready at the Corcoran Gallery of Art, but enough pictures were on the walls to give a fair idea of the lines along which the Commission had worked. Six months later, this same architect, being again in the city, said: "That hasty and incomplete view I obtained of the work of the Park Commission made a radical difference in my visit to Europe. I had never before appreciated the relations between landscape and architecture. The park plans enabled me to see Italy and Paris with new eyes, and thereby added vastly to my enjoyment and benefit."

This instance is not exceptional. The park plans came at a time when architects all over the land were beginning to feel that it was their duty, and that it might also become their privilege, to consider not alone the individual client, but also the people as a body; and especially that public buildings should be so placed as to enhance the unity, the dignity and the beauty of the city. Years of abundance have piled up capital and interest is low; and it is now both possible and profitable to build not alone for the present generation, but also for posterity. The only element now needed to accomplish in the the United States results surpassingly great is a keen but friendly rivalry among cities to excel in civic beauty and dignity as well as in commerce and manufacture. Having secured the power to live, it now remains to cultivate the joy of living. This is to be attained by making beauty a part of the every-day life of all the citizens. To this end no one thing contributes more than beautiful buildings beautifully placed, and ample parks adapted to the refreshment of both the mind and the body. Unless the Washington Park plans shall point the way to the study and practice of civic beauty throughout the United States they will fail of their highest results. In this work the American Institute of Architects, which was so potent a factor in originating the Park Commission, has a duty to perform that is too obvious to need argument.

The models, pictures, maps and plans illustrating the work of the District of Columbia Park Commission were exhibited at the Corcoran Gallery of Art for six weeks beginning on January 15, 1902; and on the same day the preliminary reports of the Senate Committee on the District of Columbia and of the Park Commission were submitted to Congress by Senator McMillan. President Roosevelt and the members of his Cabinet were present at the opening of the exhibition; and, as opportunity has offered, the members of the Administration have given to the Commission and to the plans hearty, intelligent, effective, aid and support.

It was never for a moment the purpose of Senator McMillan to seek the formal approval of Congress for plans to produce which had required the experience and training of years and the intense and absorbing study of months on the part of men who had achieved the highest measure of success in their life-work. To understand the plans requires patient study, because they aim not only to satisfy the eye trained to the perception of beauty, but they also make a direct appeal to the intellect, by reason of their seasonableness and of the historic consciousness which they embody.

Questions of art and taste are not proper subjects for discussion by any deliberative body; and Congress is accustomed to refer such questions to committees or commissions and to accept or reject an individual project at the time when the question of making an appropriation for it comes up. Moreover, many portions of the plans do not need specific Congressional action, but may be carried out by the heads of one or other of the Executive Departments, by the Commissioners of the District of Columbia, the Secretary of the Smithsonian Institution, or the officer in charge of public buildings and grounds, provided the particular individual has taken the pains to inform himself as to the plans and is in sympathy with the project. Happily, thus far, only one officer of the Government has been found who is not both willing and anxious to carry out the plans of the Park Commission. The development of the Mall system substantially along the lines laid down by Peter Charles L'Enfant under the immediate direction and supervision of George Washington and Thomas Jefferson is, by common consent, the keystone in the arch. On this depends the future of the National Capital. If the plans for this portion of the work shall be carried out, then the city of Washington will become a consistent work of art, possessing unity, dignity and beauty. If the Mall plans fail, then Washington will remain a collection of unrelated units, and the greatest opportunity ever presented to the governors of a capital city will be ignorantly, ruthlessly, wantonly cast aside. It is easily within the possibilities that Washington may become more dignified, more beautiful, more consistent in plan than Paris; and yet with a great price Paris purchased unity and dignity, whereas to Washington it is a birthright, requiring only nurture and development.

As the improvement of the Mall is the key to the development of the Capital, so the removal of the railroad from the Mall is the condition precedent to any adequate development of that space.

What properly may be called the dynamic force of the plans prepared by the Park Commission, combined with the persuasive powers of the chairman of that body, is shown by the fact that a part of the report is a reasonable proposition on the part of the Pennsylvania Railroad Company not only to sacrifice its commercially strategic position in the Mall, but also to go to great expense in promoting the general scheme by erecting at a point selected by the Commission a union railway-station of such architectural character and so fitted and furnished as to be an adequate and suitable gateway to the Capital of the United States.

The proposed union station, in size longer than the Capitol by 8 feet and 8 inches, will not only accommodate the seven railroads now entering the District of Columbia, but also provision is made for the accommodation of any new road which may secure hereafter the right to construct its lines into the District; and the national character of the structure will be recognized both by the monumental character of the building itself and its location in relation to the Capitol, and also by certain arrangements within the structure whereby the President and guests of State will have separate and suitable accommodations when entering or leaving the city of Washington.

A bill to carry out these ideal arrangements having passed the Senate and having been reported to the House with the unanimous favorable recommendation of the Committee on the District of Columbia of that body, the successful outcome of this project before the 4th of March may be anticipated with confidence.

The main axis of the great composition designed by the Park Commission as the completion of the L'Enfant plan has for its beginning the Capitol and for its centre the Washington Monument. It is essential to the integrity of the composition that the western limit of the axis shall be marked by an object worthy to stand with the two great structures mentioned. This end once accomplished, the result must be a civic composition the greatest in extent known in the modern world. After mature consideration and after consultation with those in position to give advice on such a subject the Commission recommended that the main axis be a suitable memorial to the one man in our national history who by common consent shares preeminence with George Washington — to Abraham Lincoln.

This suggestion met a prompt response on the part of Congress; a Lincoln Memorial Commission was created and $25,000 appropriated to provide for the plans. The consultations already held give promise that the type of memorial proposed (a great portico in the Doric or the Corinthian order) and the location suggested by the Park Commission will be recommended to Congress. If these views shall be accepted, then the ultimate development of the space from the Monument westward to the Potomac, an area a mile in length, must proceed according to the plans of the Commission.

On the west front of the Capitol grounds the Commission have laid out Union Square, as they have named it, a space resembling the Place de la Concorde in Paris; and this area they would adorn with statues of Grant and his two great lieutenants, Sherman and Sheridan. The Grant statue, or memorial, has been provided for, and it is within the power of the statue commission to locate it in the space recommended by the Park Commission. There is reason to believe that this location will be the one selected, and thus another stake will be driven. The location of Sheridan on Grant's left should follow without question, since no action on that project has been taken. Nor should there be great difficulty in changing the location of the still uncompleted statue of Sherman to a site on Grant's right. The present location on the axis of the Treasury is the culmination of the long series of blunders and misfortunes that have attended this statue from its inception. No comic opera contains a more absurd conceit than the position gravely maintained in connection with the Sherman statue; namely, that on the death of the artist a commission to execute a work of art becomes an asset of his estate, to be traded on by the heirs as their art knowledge, or lack of it, may dictate and the funds at their disposal may permit. Added to this absurdity is the location of the statue of William Tecumsch Sherman in John Sherman's rightful place. It is quite unnecessary to discuss the pedestal that has been prepared for the Sherman statue. It speaks for itself most loudly. It is to be hoped that the whole business will prove an awful and an effective warning.

Turning now to a pleasanter theme: the proposed union station has been adverted to as the gateway of Washington. There is a gateway by water as well as by land. Where the Anacostia joins the Potomac is the long, narrow space, beautiful for situation, known as the Washington Barracks; and there Congress has provided for the construction of the Army War College and the School of Application for the Corps of Engineers.

The main college building, with its formal gardens, will look down the Potomac to the old town of Alexandria, rich in Colonial memories, and on towards Mount Vernon, the extreme southeastern limit of the proposed park system. The officers' quarters flanking the parade grounds will present along the river front a series of porticos, with their line of white columns standing in order like a regiment on dress-parade. This work is now being carried out according to plans eminently satisfactory to the Commission.

[1] A paper by Charles Moore, Secretary of the Senate Committee on the District of Columbia.
